The remains of the Dionysiac theatre at Athens, the prototype of all later theatres, were excavated in 1862, when the proscenium, orchestra, and lower rows of seats were found in a fair state of preservation. It must have held 30,000 people; the cavea reaches from the foot of the Acropolis hill to close under the upper circuit wall. The rock-cut cavern, which was faced with the choragic monument to Thrasyllus (320 B.C.), seems to have opened behind the highest row of seats; the face of the rock is here scarped to a curve concentric with the lines of seats. The most interesting discovery was that of a row of 67 marble thrones in the front row, each inscribed with the name of one of the chief Athenian priests or with that of a secular official.[7] The cavea was divided into 13 cunei; a low wall separated the auditorium from the orchestra. The front or "riser" of the stage is decorated with fine reliefs of deities on large marble slabs. These existing features are mostly restorations of the time of Hadrian, but the reliefs themselves are of much earlier date. The floor of the orchestra is very late, formed of roughly laid slabs of stone, with a large central lozenge in marble, which may mark the limits of the thymele, and is apparently part of an earlier pavement.

---

[1] See Texier and Pullan, *Asia Minor*, London, 1865.

[2] The well-preserved theatre at Tauromenium, in Sicily, still has these niches, which are contrived in the dwarf wall on which the columns of the upper gallery stood.

[3] Earthenware vases, which are sometimes found under the floors of mediæval church stalls, were probably placed there through a mistaken notion that this was carrying out Vitruvius's recommendation.

[4] The central door, used by the chief actor, was the "royal door."

[5] Hence the Roman proverbial phrase, "deus ex machina."

[6] This is shown by Jacobs, *Verm. Schriften*, iv. p. 272, and Passow in *Zimmermann's Zeitschr. f. d. Alterth.*, 1837, No. 29.

[7] These thrones are of various dates, ranging from the reign of Augustus or even earlier to that of Hadrian; see *Papers of the American School of Classical Studies at Athens*, vol i. p. 123. Similar Greek theatre seats of earlier date still exist in the choirs of some churches in Rome, where they were once used for the episcopal or celebrant's throne. These were probably brought to Rome during the imperial period for use in the Roman theatres or amphitheatres. The finest example of pure Hellenic work is in S. Pietro in Vincoli: it is decorated with delicate honeysuckle scroll-work in relief.

The position of the Dionysiac theatre, with many of the chief temples of Athens in sight, and with its glorious view of Mount Hymettus, the blue waters of the Ægean Sea and the islands of Salamis and Ægina, should not be forgotten in reading the dramas of the great tragedians, with their impassioned appeals to the glories of nature and their allusions to the protective presence of the divine patrons of Attica.

Outside Athens the largest Greek theatres were those at Megalopolis (Paus., viii. 32), Cnidus, Syracuse, Argos, and Epidaurus. By the end of the 4th century B.C. every important Hellenic city possessed its theatre, and new ones were built or old ones restored throughout the whole period of Roman domination. The most perfect existing example is that at Aspendus in Pamphylia,[1] a building of the 2d century of our era, in which the early Greek model has been closely followed. Aspendus is the only place where the whole scena with its three orders of columns is still standing, and every row of seats exists in almost perfect condition. In this theatre the whole interior appears to have been covered by an awning,[2] supported along the top of the scena by wooden poles set in rows of perforated corbels like those on the Colosseum in Rome. The earlier Greek theatres were probably unsheltered from the sun. Next to Aspendus, the theatre of Tauromenium, in Sicily (see TAORMINA), is the best preserved, at least as far as regards the scena and the upper gallery round the cavea. That at Myra, in Lycia (Fig. 1), is also in good preservation.

The Roman Theatre.—In the main the theatres of the Romans were copied closely from those of the Greeks, but in the Greek theatre the orchestra occupied more than a semicircle, while the Romans made it exactly half a circle. The accompanying diagrams (see Fig. 3) show the principle on which the plan of each was set out.[3] The Romans also introduced another important change, in many cases constructing theatres on a level site, not scooped out of a hill-side as in the case of Hellenic theatres. This necessitated an elaborate arrangement of substructures, with raking vaults to carry the seats of the cavea, and also an additional visible façade with tiers of arches following the semicircle of the auditorium. The design universally adopted for this appears to have been tiers, usually three in number, of open arches, with intermediate engaged columns, each tier being of a different order, as is still to be seen in the remains of the theatre of Marcellus in Rome.[4] The development of the use of the stone arch, and still more the use of concrete for forming vaults, enabled the Romans to erect their theatres on any site. Those in Rome were placed in the level plain of the Campus Martius.

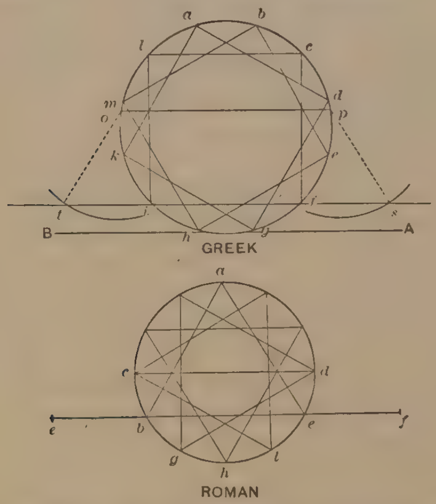

FIG. 3.—Diagram to show the principle on which the Plans of the Greek and Roman Theatre were set out.

During the Republican period the erection of permanent theatres with seats for the spectators was thought to savor of Greek luxury and to be unworthy of the stern simplicity of the Roman citizens. Thus in 154 B.C. Scipio Nasica induced the senate to demolish the first stone theatre which had been begun by C. Cassius Longinus ("tanquam inutile et nociturum publicis moribus," Liv., *Epit.*, 48). Even in 55 B.C., when Pompey began the theatre of which remains still exist in Rome, he thought it wise to place a shrine to Venus Victrix at the top of the cavea, as a sort of excuse for having stone seats below it—the seats theoretically serving as steps to reach the temple. This theatre, which was completed in 52 B.C., is spoken of by Vitruvius as "the stone theatre" *par excellence*: it is said in the Regionary catalogues to have held 40,000 people. It was also used as an amphitheatre for the bloody shows in which the Romans took greater pleasure than in the purer intellectual enjoyment of the drama. At its inauguration 500 lions and 20 elephants were killed by gladiators. Near it two other theatres were erected, one begun by Julius Cæsar and finished by Augustus in 13 B.C., under the name of his nephew Marcellus,[5] and another built about the same date by Cornelius Balbus (Suet., *Aug.*, 29; Pliny, *H. N.*, xxxvi. 12). Scanty remains exist of this last theatre, but the ruins of the theatre of Marcellus are among the most imposing of the buildings of ancient Rome.

A long account is given by Pliny (*H. N.*, xxxvi. 2 and 24) of a most magnificent temporary theatre built by the ædile M. Æmilius Scaurus in 58 B.C. It is said to have held the incredible number of 80,000 people, and was a work of the most costly splendor. Still less credible is the account which Pliny gives (*H. N.*, xxxvi. 24) of two wooden theatres built by C. Curio in 50 B.C., which were made to revolve on pivots, so that the two together could form an amphitheatre in the afternoon, after having been used as two separate theatres in the morning.

In some cases the Romans built two theatres close together, one for the Greek and the other for the Latin drama, as is the case at Hadrian's magnificent villa near Tivoli. The two theatres at Pompeii are still well preserved, and all Roman provincial towns of any importance seem to have possessed at least one theatre, designed with the semicircular orchestra after the Roman fashion (see Fig. 3). The theatres built under the Roman rule in Hellenic cities seem, on the other hand, to have been usually constructed on the old Greek model, probably because they were designed by Greek architects. This is the case at Tauromenium, Aspendus, and Myra (see Fig. 1). An important exception to this rule is the still well-preserved theatre of Herodes Atticus, at the southwest angle of the Athenian Acropolis, which has a semicircular orchestra. It was built in the reign of Hadrian by Herodes Atticus,[6] a very wealthy Greek, who spent enormous sums in beautifying the city of Athens; he called it the Regillum, after his wife Regilla. Its cavea, which is excavated in the rock, held about 6000 people; it was connected with the great Dionysiac theatre by a long and lofty porticus or stoa, of which considerable remains still exist, probably a late restoration of the stoa built by Eumenes II. of Pergamum. In the Roman theatre the "orchestra" was occupied, not by the chorus, but by senators and other persons of rank (Vitr., iii. 6).[1] The Romans used scenery and stage effects of more elaboration than was the custom in Greece. Vitruvius (iii. 7) mentions three sorts of movable scenery: (1) for the tragic drama, façades with columns representing public buildings; (2) for comic plays, private houses with practicable windows and balconies;[2] and (3) for the satyric drama, rustic scenes, with mountains, caverns, and trees.

---

[1] See Texier and Pullan, *Asia Minor*, London, 1865.

[2] There was also a wooden pent-roof corbelled out over the stage.

[3] See Vitruvius, iii. 8 (Greek theatre) and iii. 2 to 7 (Roman).

[4] This design was also adopted for their amphitheatres, such as the colossea of Rome and Capua, the plan of which resembles the cavea of two theatres set together so as to enclose an oval space.

[5] According to Livy (xl. 51), the theatre of Marcellus was built on the site of an earlier one erected by Æmilius Lepidus.

[6] This theatre was not begun when Pausanias wrote his book *Attica*, and was complete when he wrote the *Achaica* (see Paus., vii. 20). It is illustrated in *Mon. Inst.*, vi., plate 16.

The Modern Theatre.—During the Middle Ages miracle plays with sacred scenes were the favorite kind of drama; no special buildings were erected for these, as they were represented either in churches or in temporary booths. In the 16th century the revival of the secular drama, which, in the reign of Elizabeth, formed so important a part of the literature of England, was carried on in tents, wooden sheds, or courtyards of inns, mostly by strolling actors of a very low class. It was not till towards the close of the century that a permanent building was constructed and licensed for dramatic representations, under the management of Shakespeare and Burbage.[3] In the 16th and 17th centuries a favorite kind of theatrical representation was in the form of "masques," with processions of grotesquely attired actors and temporary scenic effects of great splendor and mechanical ingenuity. In the reigns of James I. and Charles I., Ben Jonson and the architect Inigo Jones worked together in the production of these "masques," Jonson writing the words and Inigo Jones devising the scenic effects, the latter being very costly and complicated, with gorgeous buildings, landscapes, and clouds or mountains, which open to display mimic deities, thrown into relief by colored lights. These masques were a form of opera, in which Ben Jonson's words were set to music. Ben Jonson received no more for his libretto than Inigo Jones did for his scenic devices, and was not unnaturally annoyed at the secondary place which he was made to occupy; he therefore revenged himself by writing severe satires on Inigo Jones and the system which placed the literary and mechanical parts of the opera on the same footing. In an autograph MS. which still exists this satirical line occurs—"Painting and carpentry are the soul of masque" (see Cunningham, *Life of Inigo Jones*, London, 1848).

In Italy, during the 16th century, the drama occupied a more important position, and several theatres were erected, professedly on the model of the classic theatre of Vitruvius. One of these, the Teatro Olimpico at Vicenza, still exists: it was designed by Palladio, but was not completed till 1584, four years after his death. It has an architectural scena, with various orders of columns, rows of statues in niches, and the three doors of the classic theatre but the whole is painted with strong perspective effects which are very unclassical in spirit. Scamozzi, Palladio's pupil, who completed the Teatro Olimpico, built another pseudo-classical theatre in 1588 at Sabbionetta for the duke Vespasiano Gonzaga, but this does not now exist.

In France the miracle play developed into the secular drama rather earlier than in England. In the reign of Louis XI., about 1467, the "Brothers of the Passion" had a theatre which was partly religious and partly satirical. In the 16th century Catherine de' Medici is said to have spent incredible sums on the dresses and scenery for the representation of the Italian ballet; and in the middle of the 17th century the regular opera was introduced at Paris.

At the end of the 18th century the theatres of San Carlo at Naples, La Scala at Milan, and La Fenice at Venice were the finest in Europe; all these have been rebuilt in the present century, but have been eclipsed by the theatres of Paris, St. Petersburg, and other capitals, both in size and architectural splendor.

In the modern theatre the auditorium has changed comparatively little, except that the stalls have gradually encroached upon and almost absorbed the pit. The arrangement of the boxes, stalls, balcony, and gallery are too well known to need description. Few people have, however, any notion of the immense size and extreme complication of the space and machinery behind the proscenium, of which the visible stage occupies but a very small proportion. The stage-floor slopes upwards away from the audience, so that it may appear deeper than it really is by diminishing the foreshortening.[4] Its extent behind the most distant plane of scenery is usually quite as great as that which the audience sees. In addition to this extension of the visible stage there are three other enormous spaces filled with the machinery to work the scenery.

(1) Of these the first consists of the "wings" (Fr. *cou-*

---

[1] The pit and stalls in a modern theatre occupy an analogous position.

[2] These are shown on Græco-Roman vases of the latest type, with paintings of burlesque parodies of mythological stories.

[3] The first building specially erected in London for dramatic purposes was built in 1576-77 by the actor James Burbage, who was originally a carpenter by trade. It was constructed of timber, and stood in Holywell, Lane, Shoreditch, till 1598, when it was pulled down; it was known as "The Theatre" *par excellence*. Of almost equally early date was the "Curtain" theatre, also in Shoreditch; many explanations of its name have been given but the real one appears to be that it was so called from the plot of ground, known as "The Curten," on which it stood. It probably continued in use till the general closing of theatres by order of the parliament in 1642.

The "Globe" theatre, famous for its association with Shakespeare, was built by James Burbage, who used the materials of "The Theatre," in the year 1598. Its site was in Southwark, in a district called "The Bankside," near the old "Bear Gardens." It was an octagonal structure of wood, with lath and plaster between the main framework. It was burnt in 1613, rebuilt, and finally pulled down and its site built over in 1644. Its name was derived from its sign of Atlas supporting the globe. Near it were two less important theatres, "The Rose," opened in 1592 by Henslowe, and "The Swan," opened in 1598 and probably owned also by Henslowe; like the Globe, it was an octagonal wood-and-plaster building.

The "Blackfriars" theatre, another of the Burbages' ventures, was built in 1596 (not 1576, as stated by Collier, *Hist. of Dramatic Poetry and Annals of the Stage* new ed., 1879, vol. i. p. 287), near the old Dominican friary. The "Fortune" theatre was built by Edward Alleyn, the great rival of the Burbages, in 1599-1600, at a total cost, including the site, of £1320 [$6415.20]. It stood between Whitecross Street and Golding Lane. It existed as late as 1819, when a drawing of it was given by Wilkinson (*Londina Illustrata*, 1819). The "Red Bull" theatre was probably originally the galleried court of an inn, which was adapted for dramatic purposes towards the close of Elizabeth's reign. Other early theatres were the "Hope" or "Paris Garden" theatre, the "Whitefriars" and "Salisbury Court" theatres, and the "Newington" theatre. A curious panoramic view of London, engraved by Visscher in 1616, shows the Globe, the Hope, and the Swan theatres.

The plan of the first English theatres appears to have had no connection with those of classical times, as was the case in Italy; it was evidently produced in an almost accidental way by the early custom of erecting a temporary platform or stage in the middle of the open courtyard of an inn, in which the galleries all around the court formed boxes for the chief spectators, while the poorer part of the audience stood in the court on all sides of the central stage. Something similar to this arrangement, unsuitable though it now seems, was reproduced even in buildings, such as the Globe, the Fortune, and the Swan, which were specially designed for the drama. In these and other early theatres there was a central platform for the stage, surrounded by seats except on one side, where there was a "green-room" or "tireynge howse." The upper galleries or boxes completely surrounded the stage, even the space over the green-room being occupied by boxes. This being the arrangement, it is easy to see why the octagonal plan was selected in most cases, though not in all,—the Fortune theatre, for example, was square. An interesting specification and contract for the building of the Fortune theatre is printed by Halliwell-Phillipps (*op. cit. infra*, p. 164). In all its details the Fortune is specified to be like the Globe, except that it is to be square in plan, and with timbers of heavier scantling. The walls are to be of wood and plaster, the roof tiled, with lead gutters, the stage of oak, with a "shadow" or cover over it, and the "tireynge-howse" to have glazed windows. Two sorts of boxes are mentioned, viz., "gentlemen's roomes" and "twoopennie roomes." A woodcut showing this arrangement of the interior is given in a collection of plays edited by Kirkman in 1672.

Much valuable information about the early theatres of London is given by Wilkinson, *Londina Illustrata* (1819), in which are engravings of some of them. See also Collier, *Hist. of Dramatic Poetry*, 1879; Halliwell-Phillipps, *Life of Shakespeare*, 1883; Malone, *History of the Stage*, 1790, republished by Boswell in 1821; the publications of the New Shakespeare Society; the Ninth Report of the Historical MSS. Commission; and a series of articles on early London theatres, by T. F. Ordish, in *The Antiquary*, vols. xi., xii., and xiv., 1885-86.

[4] This device was practiced by the mediæval architects in most European countries, who frequently made the floor of cathedrals and other large churches to slope upwards from west to east, sometimes as much as from two to three feet.

lisses), a series of chambers or platforms on each side of the stage, arranged many stories high, and reaching to more than double the height of the proscenium.

(2) The "dock" or under-space (Fr. *dessous*), extending under the whole area of the stage floor, and about equal in height to the proscenium, is divided into three or four stories by successive floors, and contains long rows of immense windlasses (Fr. *gril*) for raising and lowering scenery, and also an elaborate arrangement of lifts by which actors can suddenly appear or vanish through the stage floor. A very ingenious device called the "star trap," invented by an English mechanician (Fr. *trappe Anglaise*), allows an actor to vanish through the floor without any opening in it being visible. This is done by making the trap door of thin boards (something like a venetian blind) fixed on to flexible bands of steel; the weight of the actor makes these open in the middle and let him through, while the steel springs close the opening as soon as they are released. The whole movement is so rapid that the actor seems to sink through the solid floor.[1] In all mechanical appliances for theatrical purposes England is far ahead of other countries, many of which have adopted English methods.

(3) The third space, and the largest of all, is that above the proscenium—the "flies" (Fr. *dessus* or *cintre*), extending over the whole of the stage, and reaching sometimes to nearly double the height of the proscenium. This also is divided into many floors, and contains rows of great windlasses, by which scenery can be hoisted up out of sight, without folding or bending it. All these three parts of the building are filled with a complicated but most orderly series of ropes, lifts, and machinery of every sort, of which it is impossible here to give a detailed description.

The old method of fixing scenery was to slide it in two halves from the wings in grooves formed in the stage floor: these are no longer used, as much more realistic effects can be gained by supporting scenery from the top, or by building it up with supports of its own, so that, instead of a series of painted planes set parallel to the stage front, castles, cathedrals, or even whole streets are actually built upon the stage, and give striking effects of real perspective.

A rapidly growing tendency now exists to increase the mechanical perfection of the theatre. The extended use of iron instead of wood for the stage floor and the various machines has been a great gain in space and rapidity of working. It is now considered a great object to drop the curtain as seldom as possible, and even the Grand Opera House of Paris is now left far behind in the modern competition for mechanical perfection,[2] though from an architectural point of view it is the most magnificent and costly of all existing buildings of its kind. See Fig 4.

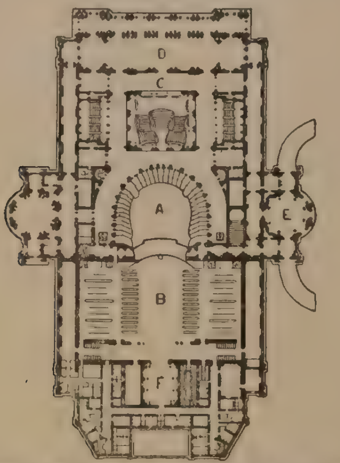

FIG. 4.—Plan of the Grand Opera House in Paris: 200 feet to the inch. A, Auditory. B, Stage. C, Grand Staircase. D, Great Saloon. E, Royal Entrance. F, Green-room.

The latest improvement to prevent delay between the scenes has been introduced in the Madison Square theatre in New York city, which has two stages, one above the other. During the performance of a scene the second stage floor is being prepared in the under-space, with all its scenery fixed, and when the curtain falls the first stage rises into the upper regions and the second floor goes up to take its place. These floors are accurately balanced by heavy counterpoise weights, so that the whole of these enormous masses are moved with comparatively little force.

On the whole, for magnificence of effort and mechanical ingenuity the great London pantomimes are unrivalled. Their transformation-scenes are marvels of the mechanists' skill, and are often devised with very high artistic talent. Unhappily much danger and suffering have often to be undergone by the women who act the part of fairies and the like, suspended high in the air by almost invisible supports, and by the young children who have to squeeze themselves into pasteboard shells representing insects or reptiles.

In addition to the above-mentioned parts of the theatre, which are reserved for the mechanical working of the performance, much space is occupied by the "green-room" for the actors, and rows of dressing-rooms. An immense deal of storage room is also required, and some of the Parisian theatres have large magazines for this purpose in the suburbs. In many cases also the atelier for the scene painters is far removed from the theatre, and thus far better space and lighting for the work can be provided. Fig. 5 shows the plan of the Drury Lane theatre, in many respects the best arranged in London.

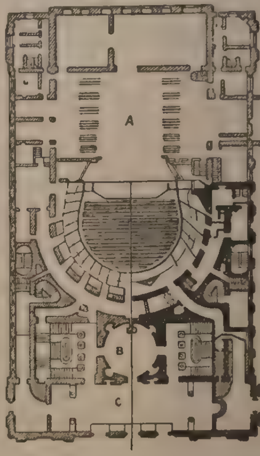

FIG. 5.—Plan of Drury Lane Theatre: 100 feet to the inch. A, Stage. B, Saloon between the Chief Staircases. C, Entrance Hall.

The painting of theatrical scenery has frequently been the work of artists of very high talent, such as Raphael in Rome, Watteau, Boucher, and Servandoni in France, and Stanfield in England. Paintings of very high artistic merit and wonderfully decorative effect are now produced for theatrical purposes, especially in France, Germany, and England.[3] In England especially great historical and antiquarian knowledge are brought to the aid of this branch of art. The landscapes in particular are sometimes works of great beauty, and very beautiful effects of lake scenery with trees and mountains reflected in the water are got by setting great sheets of plate glass over the stage floor, slightly inclined, so that a real reflection is thrown by the landscape painted on the scene behind. Another ingenious device, used by Wagner at Baireuth and also in England for magical scenes, was to form a thin and semi-transparent curtain of vapor, which was sent up by a perforated steam-pipe concealed in a groove in the stage.

The various methods of lighting used are an important item in the production of striking effects. The old system of a row of "foot-lights," with their unpleasant upward shadow, is now almost obsolete. Dip candles were used till 1720, when moulded candles were introduced into French theatres. The next improvement was the lamp of M. Argand, with its circular wick. In 1822 gas was first used in a Parisian theatre, next came the oxyhydrogen lime light, used for special effects, and now electric lighting is rapidly superseding all other kinds.

The old way of producing lightning was to blow lycopodium or powdered resin with bellows through a flame, and this is still used in realistic effects of conflagrations. More effective lightning is now made by flashing the electric light behind a scene painted with clouds, in which a zigzag aperture has been cut out and filled with a transparent substance. Thunder is made by shaking large sheets of iron, by rolling cannon balls above the ceiling of the auditorium, and by clapping together a series of planks strung together on two ropes. Wind is imitated by a machine with a cogged cylinder, which revolves against coarse cloth tightly stretched. The sound of rain is produced by shaking parched peas in a metal cylinder.

---

[1] Other varieties of this, such as the "vampire trap," allow an actor to vanish through an apparently solid wall.

[2] In 1883 M. Reyer's *Sigurd* was refused at the Paris Opera House mainly on account of the absence of the necessary mechanical appliances.

[3] Scene paintings are usually executed in distemper, frequently in an atelier formed in the roof a theatre; the artist partly works with his canvas laid upon the floor, or, where space allows, the painting is hung against a wall and the artist works from a scaffold, with tiers of boarding arranged so that he can reach to any part of the great canvas.

The orchestra is now usually arranged either below or above the proscenium, so that the musicians are not visible. The prompter is placed at one side, in the wings, so as to avoid the disfigurement of the hood-like box which formerly used to cut the front line of the stage into two halves. This is, however, less convenient for the actors.

Till the middle of the present century little trouble or expense was laid out on dresses and accessories. Certain conventional costumes, made of cheap stuff, were used for each part, with but little regard to historical correctness. Armor and weapons were made of pasteboard covered with metal foil, and stage jewelry was made of small cup-like pieces of tin formed with many facets. Now, however, no trouble or expense is spared to get the costumes and various properties archæologically correct; real jewels and the richest stuffs are often used for the dresses, as well as real furniture of the most costly sort for the furnishing of the scenic rooms. As much as £20,000 ($97,200) is sometimes spent before the play can be presented. All this splendor and realism is very hostile to the true interest of the drama; magnificent scenery and costly accessories are expected by the audience, rather than good acting. In some scenes, such as the ball in the first act of Romeo and Juliet, as recently represented at the Lyceum, the words and acting of the chief performers were almost lost in the general bustle and splendor of the scene. Frequently, too, the noise of setting up some elaborate scene behind almost drowns the voices of the actors in front of the drop scene.

Another serious cause of the present low state of acting in England is the fact that a popular play sometimes runs for several hundred nights without a break, thus reducing the performers to the condition of machines. The modern system of expending large sums on dresses and decoration naturally prevents that frequent change of subject which is so desirable, and which in France is provided for by the rules of the Théâtre Français, where acting of a very high order of merit still survives.

The present system, aided by the enormous size to which London has unhappily grown, has completely changed the character of the audience. Instead of an audience largely composed of *habitués*, who by their constant attendance at the theatre had gained some knowledge of what acting ought to be, and were prepared to show their disgust at clap-trap or ranting, we have now practically a fresh and ignorant audience every night, who, by their applause of what is worst and their coolness to real refinement of acting, do much to lower the dramatic standard and demoralize the actors.

LAW RELATING TO THEATRES.

The regulation of the theatre by legislation can be traced back to the time of the lower empire, in which it depended almost wholly upon constitutions of Theodosius and Valentinian, incorporated in the Theodosian Code (tit. xv. 5, 6, 7), and a century later to a large extent adopted by Justinian. In the whole of this law there is an evident attempt at a compromise between the doctrines of Christianity and the old Roman love of public spectacles of all kinds. It deals less with theatrical representations proper than with gladiatorial contests and chariot races.[1] The Theodosian Code provided that the sacraments were not to be administered to actors save where death was imminent, and only on condition that the calling should be renounced in case of recovery. Daughters of actors were not to be forced to go on the stage, provided that they lived an honest life. An actress was to be allowed to quit the stage in order to become a nun. There were also numerous sumptuary regulations as to the dress of actors. None of the law which has been mentioned so far was adopted by Justinian, but what follows was incorporated in *Cod.* xi. 40 ("De Spectaculis et Scenicis"), which consists entirely of extracts from the Theodosian Code of a very miscellaneous nature. Provision was made for the exhibition of public games and theatrical spectacles by magistrates, practically confining them to exhibiting in their own cities. Statues of actors were not to be placed in the public streets, but only in the proscenium of a theatre. A governor of a province was entitled to take the money raised for public games for the purpose of repairing the city walls, provided that he gave security for afterwards celebrating the games as usual. In *Cod.* iii. 12, 11 ("De Feriis") is a constitution of Leo and Anthemius forbidding dramatic representations on Sunday. The *Digest* (iii. 2) classed all who acted for hire ("omnes propter pecuniam in scenam prodeuntes") as infamous persons, and as such debarred them from filling public offices. A mere contract to perform, not fulfilled, did not, however, carry infamy with it. By the 51st of the *Novellæ* actresses could retire from the stage without incurring a penalty, even if they had given securities or taken an oath.

In England, as in other countries of western Europe, theatrical legislation was of comparatively recent introduction. Such legislation was unnecessary as long as the theatre was under the control of the church and actors under its protection (see DRAMA). The earliest regulations were therefore, as might be expected, made by the church rather than by the state. The ecclesiastical ordinances were directed chiefly against the desecration of churches, though they sometimes extended to forbidding attendance of the faithful as spectators at plays of a harmless kind.[2] Sacraments and Christian burial were denied by the canon law to actors, whose gains, said St. Thomas, were acquired *ex turpi causa*.[3] The same law forbade plays to be acted by the clergy, even under the plea of custom, as in Christmas week, and followed the Code of Justinian in enjoining the clergy not to consort with actors or be present at plays (see the *Decretals* of Gregory, iii. 1, 12 and 15, "De Vita et Honestate Clericorum"). As lately as 1603 canon lxxxviii. of the canons of the Church of England enacted that churchwardens were not to suffer plays in churches, chapels, or churchyards.

The Reformation marks the period of transition from the ecclesiastical to the non-ecclesiastical authority over the drama. Precautions began to be taken by the crown and the legislature against the acting of unauthorized plays, by unauthorized persons, and in unauthorized places, and the acting of plays objectionable to the Government on political or other grounds. The protection of the church being withdrawn, persons not enrolled in a fixed company or in possession of a license from the crown or justices were liable to severe penalties as vagrants. The history of the legislation on this subject is very curious. An Act of the year 1572 (14 Eliz. c. 5) enacted that "all fencers, bearwards, common players of interludes, and minstrels (not belonging to any baron of this realm, or to any other honorable person of greater degree)," wandering abroad without the license of two justices at the least, were subject "to be grievously whipped and burned through the gristle of the right ear with a hot iron of the compass of an inch about." This statute was superseded by 39 Eliz. c. 4, under which the punishment of the strolling player is less severe, and there is no mention of justices. The jurisdiction of justices over the theatre disappears from legislation from that time until 1788. In 39 Eliz. c. 4, there is a remarkable exception in favor of persons licensed by Dutton of Dutton in Cheshire, in accordance with his claim to liberty and jurisdiction in Cheshire and Chester, established in favor of his ancestor by proceedings in *quo warranto* in 1499. The stricter wording of this Act as to the license seems to show that the license had been abused, perhaps that in some cases privileges had been assumed without authority. In 14 Eliz. c. 5 the privileges of a player attached by service of a noble or license from justices, in the later Act only by service of a noble, and this was to be attested under his hand and arms. The spirit of the Acts of Elizabeth frequently appears in later legislation, and the unauthorized player was a vagabond as lately as the Vagrant Act of 1744, which was law till 1824. He is not named in the Vagrant Act of 1824. The Theatre Act of 1737 narrowed the definition of a player of interludes, for the purpose of punishment as a vagabond, to mean a person acting interludes, etc., in a place where he had no legal settlement.

---

[1] The word *ludi* seems sometimes to include, sometimes to exclude, dramatic performances. Its meaning in a particular instance depends on the context.

[2] A large number of such ordinances will be found cited in Prynne, *Histriomastix*; Bossuet, *Maximes et Reflexions sur la Comédie*; Mariana, *De Spectaculis*; Smith, *Dictionary of Christian Antiquities*, arts. "Actors" and "Theatres."

[3] For this reason it appears to have been the custom in France for actors to be married under the name of musicians. See *Hist. Parlementaire de la Révolution Française*, vol. vi. p. 381. The difficulties attending the funeral of MOLIÈRE (*q.v.*) are well known.

Before the Restoration there were privileged places as well as privileged persons, *e g.*, the court, the universities, and the inns of court. With the Restoration privilege became practically confined to the theatres in the possession of those companies (or their representatives) established by the letters patent of Charles II. in 1662 (see DRAMA). In spite of the patents other and unprivileged theatres gradually arose. In 1735, Sir John Barnard introduced a bill "to restrain the number of playhouses for playing of interludes, and for the better regulation of common players." On Walpole's wishing to add a clause giving parliamentary sanction to the jurisdiction of the lord chamberlain, the mover withdrew the bill. In 1737 Walpole introduced a bill of his own for the same purpose, there being then six theatres in London. The immediate cause of the bill is said to have been the production of a political extravaganza of Fielding's, *The Golden Rump.* The bill passed, and the Act of 10 Geo. II. c. 28 regulated the theatre for more than a century. Its effect was to make it impossible to establish any theatre except in the city of Westminster, and in places where the king should in person reside, and during such residence only. The Act did not confine the prerogative within the city of Westminster, but as a matter of policy it was not exercised in favor of the non-privileged theatres, except those where the "legitimate drama" was nót performed. The legitimate drama was thus confined to Covent Garden, Drury Lane, and the Haymarket from 1737 to 1843. In the provinces patent theatres were established at Bath by 8 Geo. III. c. 10, at Liverpool by 11 Geo. III. c. 16, and at Bristol by 18 Geo. III. c. 8, the Act of 1737 being in each case repealed *pro tanto.* The acting of plays at the universities was forbidden by 10 Geo. II. c. 19. It is not a little remarkable that the universities, once possessing unusual dramatic privileges, should not only have lost those privileges, but have in addition become subject to special disabilities. The restrictions upon the drama were found very inconvenient in the large towns, especially in those which did not possess patent theatres. In one direction the difficulty was met by the lord chamberlain granting annual licenses for performances of operas, pantomimes, and other spectacles not regarded as legitimate drama. In another direction relief was given by the Act of 1788 (28 Geo. III. c. 30), under which licenses for occasional performances might be granted in general or quarter sessions for a period of not more than sixty days. The rights of patent theatres were preserved by the prohibition to grant such a license to any theatre within 8 miles of a patent theatre. During this period (1737–1843) there were several decisions of the courts which confirmed the operation of the Act of 1737 as creating a monopoly. The exclusive rights of the patent theatres were also recognized in the Music Hall Act of 1752, and in private Acts dealing with Covent Garden and Drury Lane, and regulating the rights of parties, the application of charitable funds, etc. (see 16 Geo. III. cc. 13, 31; 50 Geo. III. c. ccxiv; 52 Geo. III. c. xix; 1 Geo. IV. c. lx.). The results of theatrical monopoly were beneficial neither to the public nor to the monopolists themselves. In 1832 a select committee of the House of Commons recommended the legal recognition of "stage-right" and the abolition of theatrical monopoly. The recommendations of the report as to stage-right were carried out immediately by Bulwer Lytton's Act, 3 and 4 Will. IV. c. 15 (see COPYRIGHT). But it was not till 1843 that the present Theatre Act, 6 and 7 Vict. c. 68, was passed, a previous bill on the same lines having been rejected by the House of Lords. The Act of 1843 inaugurated a more liberal policy, and there is now complete "free trade" in theatres, subject to the conditions imposed by the Act. The growth of theatres since that time has been enormous. In 1885 there were forty-six licensed under the Act in London, Liverpool coming next with ten. Nor does the extension seem to have been attended with the social dangers anticipated by some of the witnesses before the committee of 1832.

The suppression of objectionable plays was the ground of many early statutes and proclamations. While the religious drama was dying out, the theatre was used as a vehicle for enforcing religious and political views not always as orthodox as those of a miracle play. Thus the Act of 34 and 35 Hen. VIII. c. 1 made it criminal to play in an interlude contrary to the orthodox faith declared, or to be declared, by that monarch. Profanity in theatres seems to have been a crying evil of the time. The first business of the Government of Edward VI. was to pass an Act reciting that the most holy and blessed sacrament was named in plays by such vile and unseemly words as Christian ears did abhor to hear rehearsed, and inflicting fine and imprisonment upon any person advisedly contemning, despising, or reviling the said most blessed sacrament (1 Edw. VI. c. 1). A proclamation of the same king in 1549 forbade the acting of interludes in English on account of their dealing with sacred subjects. In 1556 the council called attention to certain lewd persons in the livery of Sir F. Leke representing plays and interludes reflecting upon the queen and her consort and the formalities of the mass. The same queen forbade the recurrence of such a representation as the mask given by Sir Thomas Pope in honor of the princess Elizabeth at Hatfield, for she "misliked these follies." By the Act of Uniformity, 1 Eliz. c. 2, it was made an offence punishable by a fine of a hundred marks to speak anything in the derogation, depraving, or despising of the Book of Common Prayer in any interludes or plays. In 1605 "An Act to restrain the Abuses of Players" made it an offence punishable by a fine of £10 to jestingly or profanely speak or use certain sacred names in any stage play, interlude, show, may-game, or pageant (3 Jac. I. c. 21). In consequence of the appearance of players in the characters of the king of Spain and Gondomar, an ordinance of James I. forbade the representation on the stage of any living Christian king. The star chamber in 1614 fined Sir John Yorke for representing a Catholic drama in his house. The first Act of the reign of Charles I. forbade acting on Sunday (see SUNDAY). Puritan opposition to the theatre culminated in the ordinance of the Long Parliament (see vol. vii. p. 375). After the Restoration there are few royal proclamations or ordinances, the necessary jurisdiction being exercised almost entirely by parliament and the lord chamberlain. One of the few post-Restoration royal proclamations is that of February 25, 1665, restraining any but the company of the Duke of York's theatre from entering at the attiring house of the theatre.

Preventive censorship of the drama by an officer of state dates from the reign of Elizabeth, and is perhaps the only example of censorship of the press still existing in the United Kingdom (see PRESS LAWS). Such a censorship is not unknown in other countries, and it seems to have existed even in republican Rome, if one may judge from Horace's line,

> "Quæ neque in æde sonent certantia judice Tarpa."

The master of the revels appears to have been the dramatic censor from 1545 to 1624, when he was superseded by the lord chamberlain. In some cases the supervision was put into commission. Thus with Tilney, the master of the revels in 1581, were associated by order of the privy council a divine and a statesman. In other cases it was delegated, as to Daniel the poet by warrant in 1603. The proposal to give statutory authority to the jurisdiction of the lord chamberlain led, as has been already stated, to the withdrawal of Sir John Barnard's bill in 1735, and to considerable debate before the bill of 1737 became law. Lord Chesterfield's objection to the bill in the House of Lords was not unreasonable. "If the players," said he, "are to be punished, let it be by the laws of their country, and not by the will of an irresponsible despot." The discretion reposed by the Acts of 1737 and 1843 in the lord chamberlain has been, according to the report of a select committee of the House of Commons in 1866, on the whole wisely exercised. On the other hand, there have been instances where perhaps both he and his subordinate officer, the examiner of stage plays, have been somewhat nice in their objections. Thus, during the illness of George III., *King Lear* was inhibited. George Colman, when examiner, showed an extraordinary antipathy to such words as "heaven" or "angel." The lord chamberlain's powers are still occasionally exerted in the interests of public decency, less frequently for political reasons. Before 1866 the lord chamberlain appears to have taken into consideration the wants of the neighborhood before granting a license, but since that year such a course has been abandoned.

The existing law of theatres is mainly statutory. It will be convenient to treat it as it regards the building, the performance, and the licensing of the building and of the performance. A theatre may be defined with sufficient accuracy for the present purpose as a building in which a stage play is performed for hire. It will be seen from the following sketch of the law that there are a considerable number of different persons, corporate and unincorporate, with jurisdiction over theatres. A consolidation of the law seems urgently required, and the placing of jurisdiction in the hands of a central authority for the United Kingdom. The committee of 1866 recommended the transfer to the lord chamberlain of the regulation of all places of amusement, and an appeal from him to the home secretary in certain cases, as also the extension of his authority to preventive censorship in all public entertainments; but no legislation resulted. Several bills for the amendment of the law have been recently introduced, but hitherto without success in the face of more burning political questions.

Building.—A theatre at any rate to make it such a building as can be licensed) must be a permanent building, not a mere tent or booth, unless when licensed by justices at a lawful fair by § 23 of the Act of 1843. It must, if in the metropolis, conform to the regulations as to structure contained in the Metropolitan Building Acts and the Metropolis Management Acts, especially the Act of 1878 (41 and 42 Vict. c. 32). This Act makes a certificate of structural fitness from the Board of Works necessary as a condition precedent for license in the case of all theatres of a superficial area of not less than 500 square feet licensed after the passing of the Act, gives power to the board in certain cases to call upon proprietors of existing theatres to remedy structural defects, and enables it to make regulations for protection from fire. Such regulations were issued by the board on May 2, 1879. As to theatres in provincial towns, the Towns Improvement Act, 1847, and the Public Health Act, 1875, confer certain limited powers over the building on municipal corporations and urban sanitary authorities. In many towns, however, the structural qualifications of buildings used as theatres depend upon local Acts and the by-laws made under the powers of such Acts. To a more limited extent the rules made by justices may enforce certain structural requirements.

Performance.—To constitute a building where a performance takes place a theatre, the performance must be (*a*) of a stage play, and (*b*) for hire. (*a*) By § 23 of the Act of 1843 the word "stage-play" includes tragedy, comedy, farce, opera, burletta, interlude, melodrama, pantomime, or other entertainment of the stage, or any part thereof. The two tests of a stage play appear to be the excitement of emotion and the representation of action. The question whether a performance is a stage play or not seems to be one of degree, and one rather of fact than of law. A *ballet d'action* would usually be a stage play, but it would be otherwise with a *ballet divertissement.* § 14 empowers the lord chamberlain to forbid the acting of any stage play in Great Britain whenever he may be of opinion that it is fitting for the preservation of good manners, decorum, or the public peace to do so. § 15 imposes a penalty of £50 $243] on any one acting or presenting a play or part of a play after such inhibition, and avoids the license of the theatre where it appears. Regulations of police respecting the performance are contained in 2 and 3 Vict. c. 47, and in many local Acts. A performance may also be proceeded against as a nuisance at common law, if, for instance, it be *contra bonos mores* or draw together a great concourse of vehicles, or if so much noise be heard in the neighborhood as to interfere with the ordinary occupations of life. Very curious instances of proceedings at common law are recorded. In 1700 the grand jury of Middlesex presented the two playhouses and also the bear-garden on Bankside (the "Paris garden" of *Henry VIII.*, act v. sc. 3) as riotous and disorderly nuisances. In 1819 certain players were prosecuted and convicted before the court of great sessions of Wales for acting indecent open-air interludes at Berriew, in Montgomeryshire. Performances on Sunday, Good Friday, and Christmas day are illegal (see SUNDAY). Regulations as to the sale of intoxicating liquors during the performance are made by the Licensing Acts and other public general Acts, as well as by local Acts and rules made by justices. It is frequently a condition of the license granted to provincial theatres that no excisable liquors shall be sold or consumed on the premises. The Children's Dangerous Performances Act, 1879 (42 and 43 Vict. c. 34), forbids under a penalty of £10 [$48.60] any public exhibition or performance whereby the life or limbs of a child under the age of fourteen shall be endangered. It also makes the employer of any such child indictable for assault where an accident causing actual bodily harm has happened to the child, and enables the court on conviction of the employer to order him to pay the child compensation not exceeding £20 [$97.20]. (*b*) The performance must be for hire. § 16 of the Act of 1843 makes a building one in which acting for hire takes place, not only where money is taken directly or indirectly, but also where the purchase of any article is a condition of admission, and where a play is performed in a place in which excisable liquor is sold. In a recent case of Shelley *v.* Bethell (*Law Reports*, 12 Queen's Bench Division, 11) it was held that the proprietor of a private theatre was liable to penalties under the Act, though he lent the theatre gratuitously, because tickets of admission were sold in aid of a charity.

Licensing of Building.—By § 2 of the Act of 1843 all theatres (other than patent theatres) must be licensed. By § 7 no license is to be granted except to the actual and responsible manager, who is to be bound by himself and two sureties for due observance of rules and for securing payment of any penalties incurred. The metropolitan theatres other than the patent theatres (as far at least as they are included in the boroughs named in the Act of 1843) are licensed by the lord chamberlain. By § 4 his fee on grant of a license is not to exceed 10s. [$2.43] for each month for which the theatre is licensed. The lord chamberlain appears to have no power to make suitable rules for enforcing order and decency. He can, however, by § 8, suspend a license or close a patent theatre where any riot or misbehavior has taken place.

Provincial theatres fall under three different licensing authorities. The lord chamberlain licenses theatres in Windsor and Brighton and theatres situated in the places where the queen occasionally resides, but only during the time of such occasional residence (§ 3). Theatres at Oxford and Cambridge, or within 14 miles thereof, are licensed by the justices having jurisdiction therein, but before any such license can come into force the consent of the chancellor or vice-chancellor must be given. The rules made by the justices for the management of the theatre are subject to the approval of the chancellor or vice-chancellor, who may also impose such conditions upon the license as he thinks fit. In case of any breach of the rules or conditions, he may annul the license (§ 10). All other provincial theatres are licensed by four or more justices at a special session held within twenty-one days after application for a license shall have been made to them (§ 5). The fee is not to exceed 5s. [$1.22] for each month for which the theatre is licensed (§ 6). The justices, like the lord chamberlain, appear to have no discretion as to granting a license. Their act is purely ministerial and confined to ascertaining that the applicant is the actual and responsible manager, and that he and his sureties are of sufficient substance to provide the requisite bonds. § 9 gives the justices authority to make at the special session suitable rules for enforcing order and decency at the theatres licensed by them, and of rescinding or altering such rules at a subsequent special session. It also gives a secretary of state power to rescind or alter such rules, and to make other rules. In case of riot or breach of the rules, the justices may order the theatre to be closed, and it thereupon becomes an unlicensed house. Penalties are imposed by the Act for keeping or acting in an unlicensed theatre, and for producing or acting in an unlicensed play.

Licensing Performance.—A stage play must be duly licensed before performance. § 12 of the Act of 1843 prescribes that a copy of every new play and of every addition to an old play, and of every new prologue or epilogue or addition thereto (such copy to be signed by the master or manager), shall be sent to the lord chamberlain, and, if the lord chamberlain does not forbid it within seven days, it may be represented. § 13 empowers the lord chamberlain to fix a scale of fees for examination; the fee is now two guineas [$10.20] for a play of three or more acts, one guinea for a play of less than three acts. All plays represented previously to the act are held to be licensed. A play once licensed is licensed once for all, unless the license be revoked under § 14. The examination is the duty of a special officer of the lord chamberlain's department, the examiner of stage plays.

Music Halls.—Music was at no time the object of restrictions as severe as those imposed upon the drama. The present Music Hall Act (25 Geo. II. c. 36) was passed in 1752, probably in consequence of the publication in 1751 of Fielding's *Inquiry into the Causes of the late Increase of Robbers.* It is remarkable that two works of the same writer should from opposite causes have led to both theatre and music hall legislation of lasting importance. The Act was originally passed for a term of three years, but was made perpetual by 28 Geo. II. c. 19. It applies only to music halls within 20 miles of London and Westminster. Every such music hall must be licensed at the Michaelmas quarter sessions, the license to be signified under the hands and seals of four or more justices. The license may be granted for music or dancing or both. Public notice of the license is to be given by affixing over the door the inscription "Licensed pursuant to Act of Parliament of the twenty-fifth of King George the Second." The penalty for keeping an unlicensed music hall is £100 [$486]. Music halls beyond the radius of 20 miles from London and Westminster are usually governed by local legislation, which in most cases follows, *mutatis mutandis*, the lines of the Act of 1752. The music hall, like the theatre, must generally fulfil certain structural requirements. In one important respect the law is more lenient to the music hall than to the theatre. A license is necessary for a single performance of a stage play, but it is only habitual music or dancing that requires a music hall license.

Scotland.—In Scotland the theatre has always exercised a smaller amount of influence than in England, and there has been little exclusively Scotch legislation on the subject. An Act of 1555, c. 40, discountenanced certain amusements of a semi-theatrical kind by enacting that no one was to be chosen Robert Hude (*sic*), Little John, abbot of Unreason, or queen of May. A proclamation of James VI. in 1574, and an Act of 1579, c. 12, followed the lines of English legislation by making persons using unlawful plays, such as jugglery or fast and loose, punishable as vagabonds. In 1574 the General Assembly claimed to license plays, and forbade representations on Sunday. As in England, the licensing power seems then to have passed from the church to the crown, for in 1599 James VI. licensed a theatre at Edinburgh. The Act 1672, c. 21, exempted comedians while upon the stage from the sumptuary provisions of the Act respecting apparel. The chamberlain of Scotland, while such an office existed, appears to have exercised a certain police jurisdiction over theatres. The Theatre Act of 1843 extends to Scotland, as did also the previous Act of 1737.

Ireland.—Theatrical legislation, as far as it went, was based upon English models. Thus ridicule of the liturgy was forbidden by 2 Eliz. c. 2 (Ir.); common players of interludes and wandering minstrels were deemed vagabonds, 10 and 11 Car. I. c. 4 (Ir.). In 1786 an Act was passed to enable the crown to grant letters patent for one or more theatres in Dublin city and county, 26 Geo. III. c. 57 (Ir.). The preamble alleges that the establishing of a well-regulated theatre at the seat of government will be productive of public advantage and tend to improve the morals of the people. Exceptions from the restrictions of the Act were made in favor of entertainments for the benefit of the Dublin lying-in hospital and exhibitions of horsemanship or puppet shows.

United States.—Public entertainments, dramatic or otherwise, are usually under the control of the municipal authorities. In some States, such as New York and Massachusetts, there is State legislation, requiring places of public entertainment to be licensed by the proper authority. In many States it is a condition of the license that intoxicating liquors shall not be sold in such places. Other conditions, more or less usual, are that there shall be no Sunday or dangerous performances, that acrobats shall be properly protected, and that female waiters shall not be employed. Structural qualifications are in some cases made necessary. Thus in 1885 the New York legislature passed an Act containing many minute provisions for ensuring the safety of theatres against fire. A characteristic piece of legislation is the New York Act of 1873, c. 186, enacting that no citizen is to be excluded from a theatre by reason of race, color, or previous condition of servitude. This Act of course merely carries out the important principle affirmed in art. xiv. of the amendments to the constitution of the United States. See PRIVILEGE.

The most recent if not the only work on the law relating to theatres is Geary's *Law of Theatres and Music Halls*, 1885. (J. W†.)

THEBES. See EGYPT, vol. vii. p. 673 *sq.*

THEBES (anciently Θῆβαι, *Thebæ*, or in poetry sometimes Θήβα, in modern Greek *Phiva*, or, according to the corrected pronunciation, *Thivæ*), one of the most interesting towns in Greece, is situated on low hilly ground of gentle slope a little north of the range of Cithæron, which divides Bœotia from Attica, and on the edge of the Bœotian plain, about 44 miles from Athens, whence it is now reached by two carriage-roads. It has about 3500 inhabitants, and is the seat of a bishop. The present town occupies the site of the ancient citadel, the Cadmea; two fragments of ancient wall are visible on the north, and another, belonging either to the citadel or the outer wall, on the south. Two streams, rising a little south of the town, and separated by an average distance of about half a mile, flow on the two sides, and are lost in the plain. These are the ancient Ismenus on the east and Dirce (Δίρκη) on the west, which gave to the town its name διπόταμος. The Dirce, now Platziótissa, has several springs. From the west side of the Cadmea another copious fountain (Paraporti) falls to the Dirce. In a suburb to the east is another (Fountain of St. Theodore), and northwest are two more. The Cadmea itself is supplied with water brought from an unknown source to the south by works supposed of prehistoric antiquity. It now enters the town by an aqueduct of twenty arches of Frankish construction. The "waters" of Thebes are celebrated both by Pindar and by the Athenian poets, and the site is still, as described by Dicæarchus (3d century B.C.), "all springs," κάθυδρος πᾶσα. One, from which a pasha of Negroponte (Eubœa) is said to have supplied his table, is still called "the spring of the cadi." Some of the marble basins, seats, etc., remain, and, with the fragments of wall above mentioned, are the only relics of the classic time. The most curious of later buildings is the church of St. Luke, southeast of the Cadmea, believed to contain the tomb of the evangelist. From the abundance of water the place is favorable to gardens, and the neighboring plain is extremely fertile. But the population is scanty, and the town at present of no importance.

In prehistoric times the Cadmea, with the enlarged city of Thebes into which it developed, was a power of the first rank, as is shown by its unrivalled legends. More particularly the mythical wars with Argos (see below) point to a time when the "Hellenes" of North Greece were still contending unequally against the "Achæans" of the Peloponnesus. In the legend as given by Æschylus these names are accurately preserved. At the beginning of continuous history (6th century B.C.) Thebes had long been possessed by immigrants from Thessaly, who knew the previous inhabitants as Cadmeans (Καδμεῖοι).

The history of the town to the end of the 4th century is part of the general history of the nation (see GREECE). It had an aristocratic constitution, and claimed a contested sovereignty over the other towns of Bœotia. Down to 371 B.C. this status was not essentially changed. The battle of Coronea (394) showed the increasing military strength of the Thebans, and in 371 the genius of Epaminondas raised them by the victory of Leuctra for a brief period to the leading position in Hellas. Philip of Macedon spent part of his youth as a hostage at Thebes, and probably learnt there important lessons in war. By him and his successor the state was destroyed. In 338 the Thebans shared with the Athenians the defeat of Chæronea, and received a Macedonian garrison; the lion-monument erected by them on the field of battle, and still existing there, though in fragments, is a more impressive memorial of their greatness than anything now visible at the town itself. In 335, after the death of Philip, they revolted, and were punished by Alexander with a fearful vengeance. It is said that 6000 Thebans were slain at the capture and 30,000 taken prisoners. The population was dispersed, and the town entirely razed (except, according to tradition, the house of the poet Pindar); and, though it was soon restored by the Macedonian Cassander (315), it never again played a leading part in history. In 86 B.C., having sided against the Romans in the Mithradatic war, it was plundered by Sulla, and fell into such decay that Strabo describes it as little better than a village. In the 2d century the traveller Pausanias, who gives a full account of it (ix. 5 *sq.*), found only the citadel inhabited. In 395 A.D., however, it had some strength, for Alaric, on his way to the capture of Athens, did not think fit to attack it. In the later times of the Eastern empire (10th to 12th century) it again became wealthy and important, being specially celebrated for the manufacture of silk and cloth. In 1143 it was plundered by the Normans of Sicily (who transferred thither the chief artisans of the silk trade), and, after the capture of Constantinople by the crusaders (1204), became with Athens a fief of the feudal empire. In 1311 it was again plundered by the Catalan Grand Company, a body of Spanish mercenaries, and appears to have had no return of prosperity.

Of more lasting effect than the politics of Thebes have been its legends. Bœotia, or rather the Cadmeis (Thucyd., i. 12), was a land of poetry from extremely ancient times, and the stories of Thebes are in Greek literature as important as those of Troy. The legends of the five chief groups will be found under the names indicated in the following division: (1) the foundation of the Cadmea by Cadmus; (2) the foundation by Amphion,—to this belong originally the "seven-gated" wall, the name of ἑπτάπυλος Θήβη, and the legends of Zethus, Antiope, and Dirce; (3) war of the "Seven" (under Adrastus of Argos); war of the Epigoni, or "descendants" of the Seven; the story of Œdipus; (4) legends of Bacchus,—at Thebes as elsewhere this religion was comparatively late, but became characteristic of the town; (5) legends of Heracles (commonly found with those of Bacchus; Thebes was reputed the birthplace of both). From the epic poems, of which little but titles remain, these tales descended to the Attic tragedians; upon them are founded the *Seven against Thebes* of Æschylus, the *Œdipus Tyrannus*, *Œdipus Coloneus*, and *Antigone* of Sophocles, the *Phœnissæ*, *Supplices*, and *Bacchæ* of Euripides, etc., with innumerable plays not extant. Apart from direct imitation of these works, the stories themselves, through Statius, Boccaccio, and others, have exercised a great influence on modern literature. In historical times the Thebans were not conspicuous for intellectual accomplishments, but their reputation is sufficiently sustained by Pindar, perhaps the most distinctively Hellenic of all the national poets.

The most famous monument of ancient Thebes was the outer wall with its seven gates, which even as late as the 6th century B.C. was probably the largest of artificial Greek fortresses. The names of the gates vary, but four are constant,—the Prœtides, Electræ, Neistæ or Neitæ, and Homoloides; Pausanias gives the others as Ogygiæ, Hypsistæ, Crenææ. There is evidence that the gate Electræ was on the south, and near it was the tomb of the Thebans who fell at the capture by Alexander. The gates shown to Pausanias as Neistæ and Prœtides led respectively northwest and northeast. Two of the springs have been identified with some probability,—that of St. Theodore with the Œdipodea in which Œdipus is said to have purged himself from the pollution of homicide, and the Paraporti with the dragon-guarded fountain of Ares (see CADMUS). Dicæarchus, referring to the town of Cassander, gives two measurements for the circuit, equal to about 9 miles and 5½ miles, but even the smaller is impossible for the wall, and they probably refer to the territory proper of the town, or γῆ Θηβαίς. Beyond this the topography is wholly uncertain. From the interest of the site in history and still more in literature, as the scene of so many dramas, the temptation to fix details has been specially strong. Conjectural plans or descriptions, differing widely, are given by Leake, Forchhammer, Ulrichs, Bursian, and others (references below). All are based on the assumption that the description of Pausanias and the allusions of the Attic tragedians may be read together and combined, and that the result will give the plan as it existed in the 5th and 4th centuries B.C. But to this two objections must be taken. (1) The account of Pausanias, even when clear in itself, is very uncertain evidence for anything earlier than the destruction by Alexander. It is said indeed that the restored town occupied the same area, but this is consistent with great disturbance of tradition; and we have further to allow for inaccurate transmission through 450 years of decadence, and finally for the quality of Pausanias's information, given apparently by casual guides to a traveller extremely uncritical. (2) It may be doubted whether the tragedians had accurate knowledge of Theban topography, and they had certainly no reason for introducing it in their plays. Their plots are laid in a remote past; and it is difficult to suppose them on the one hand so careful as to fit their scenes to the actual Thebes, and on the other hand so careless as to presume that it had suffered no great change between the times of Cadmus or of Œdipus and their own days. Indeed they did not make this mistake. The plays which contain most references to topography are the *Seven against Thebes* and the *Phœnissæ*. In the *Seven* the name of "Thebes" does not occur at all (the title is a misnomer, probably not given by the author); the town is called by its ancient name "The Cadmea" (Καδμεία πόλις), and the whole play assumes that the "city of Cadmus" was much smaller than the Thebes contemporary with Æschylus can have been. In the *Phœnissæ* the circuit of the walls is said to be so small that a person within must necessarily know all that had taken place in a general attack (v. 1356). None of the conjectural plans would approximately satisfy this, nor can it have been true for the time of Euripides. After this, it is not surprising to find that the attempt to use the plays as evidence is involved in unanswered difficulties, a few of which are given below.

In itself, however, and as relating to the ruins of the restored town merely, the description of Pausanias is curious and interesting. The principal buildings were at that time (2d century) the temple of Apollo Ismenius, which must have stood somewhere about the present church of St. Luke, the theatre, near the gate Prœtides, the Heracleum, with a gymnasium and race-course, and the temples of Artemis Eucleia, of Ammon, and of Fortune (Τύχη). Besides these Pausanias was shown all the gates, all the legendary sites, the house of Pindar (northwest beyond the Dirce), statues, etc., dedicated by him, several statues of immense antiquity, others attributed to the greatest artists, and in fact much more than it is easy to believe.

1. *Apollo Ismenius* and *Apollo Spodius.*—Sophocles (*Œ. T.*, 21) mentions as one of the Theban sanctuaries, "the oracular ashes of Ismenus," Ἰσμηνοῦ μαντεία σποδός. Pausanias, who calls the river not Ismenus but Ismenius, describes (1) a temple of Ismenius or Apollo Ismenius (ix. 10, 2), and (2) an altar of Apollo Spodius, made of ashes and used in a peculiar manner as an oracle (ix. 11, 7). We should suppose from Sophocles that both observations related to the same sanctuary; and Sophocles clearly identified the two. But in Pausanias they are in different places and have no connection at all. Either therefore the topography and ritual of the one period differed from those of the other, or, which is equally probable, the poet used Theban names without regard to accuracy.

2. *The Fountain of Ares.*—Euripides, in the *Supplices* (v. 650 *sq.*) describes an army advancing on Thebes from the south as having its right at the Ismenian hill, its left at the fountain of Ares, and "the chariots below the monument of Amphion." Pausanias also places the Ismenian hill on the right of the southern gate. But the fountain of Ares he places on the same side, a description quite inconsistent with this and other allusions. Ulrichs, while insisting on the agreement about the hill, merely observes on this that Pausanias is unintelligible. Of a still greater difficulty he says nothing. The tomb of Amphion is placed by Æschylus north of the town, and there or in that direction was shown to Pausanias. The topographers accordingly suppose that the "chariots" of Euripides were in the plain to the north. But there is no suggestion in the passage that any part of the advancing army was separated from the rest, and the observer expressly says that *he was at the place where the chariots fought and had a particularly good view of this part of the battle* (v. 684). Now he stood on the gate Electræ, *i.e.*, as far as possible from the tomb of Amphion, as placed by Æschylus and Pausanias. It is impossible to make a consistent account of this, and it seems plain that Euripides took up the name "tomb of Amphion" at hazard, and ignored or forgot that the real tomb could not be brought into his picture.

3. *The Altar of (Athena) Onca.*—This was shown to Pausanias (ix. 12, 1), who was told that it marked the place where the lying down of a cow indicated to Cadmus the site destined for his city (ἔδει ἐνταῦθα οἰκῆσαι). "It is said," he continues, "that in the acropolis there was formerly the house of Cadmus (Κάδμου οἰκία)." No other indication is given as to the place of the altar, and the natural inference is that it was shown in the Cadmea. But Æschylus (*Septem*, 501) places it outside the walls. Accordingly it is suggested that the oracular sign only indicated the neighborhood of the destined site, and that the altar shown to Pausanias was near that of Apollo Spodius, which is mentioned last before it, and may have been outside the wall. But this juxtaposition proves nothing about the place of Onca, for Pausanias himself shows that mention of Onca here is suggested by a reference to "oxen" in connection with the altar of Spodius, which brought to his mind the "cow" of the other legend.

4. *The Tomb of Amphion and Zethus.*—Apart from the confusion of Euripides already noticed, there is a difficulty about the mention of this monument in Pausanias and Æschylus. Pausanias, after describing several buildings near the gate Prœtides, concluding with some in the market-place, mentions next (without further indication of place) the tomb of Amphion and Zethus, and continues thus,—"the way from Thebes to Chalcis (northeast) is by this gate Prœtides, etc." Æschylus places the tomb of Amphion outside the wall opposite the north gate (*Septem*, 527), and the Prœtides elsewhere. Ulrichs concludes that Pausanias "evidently" went out by the north gate to view the monument and then returned to the Prœtides. Of course this is possible, but it is useless to draw exact inferences from documents which require such an hypothesis. It is equally probable that Pausanias identified the tomb with a monument called the Ampheion, which seems (Ulrichs, p. 17) to have been somewhere near the market-place. Indeed, there is no proof that they were not identical, for the only evidence that the tomb was outside the wall (and therefore different from the Ampheion) is that of Æschylus and Euripides, whose imaginary cities were not much larger than the Cadmean hill, and must have excluded the Ampheion itself.

On the history, see references under GREECE; on the topography and legends, Ulrichs, *Reisen und Forschungen in Griechenland*, ii. 1 *sq.*; Leake, *Travels in Northern Greece*, ii. xiv.; Bursian, *Geographie von Griechenland*, i. 225 *sq.*; and the "*Seven against Thebes*," ed. by A. W. Verrall, "Introduction." (A. W. V.)

THECLA, ST., virgin, is commemorated by the Latin Church on September 23. The *Breviary* relates that she was born of illustrious parentage at Iconium, and came under the personal teaching of the apostle Paul. In her eighteenth year, having broken her engagement with Thamyris, to whom she had been betrothed, she was accused by her relations of being a Christian, and sentenced to be burned. Armed with the sign of the cross, she threw herself upon the pyre, but, the flames having been extinguished by a sudden rain, she came to Antioch, where she was exposed to the wild beasts, then fastened to bulls that she might be torn asunder, then thrown into a pit full of serpents, but from all these perils she was delivered by the grace of Christ. Her ardent faith and her holy life were the means of converting many. Returning once more to her native place, she withdrew into a mountain solitude, and became distinguished by many virtues and miracles, dying at the age of ninety. She was buried at Seleucia.

The substance of the foregoing narrative, with many other curious incidents, occurs in the very ancient apocryphal book entitled the περίοδοι of Paul and Thecla (*Acta Pauli et Theclæ*). Tertullian tells us that this work was written by a presbyter in Asia, "out of love to Paul," but that his conduct was not approved, and led to his deposition. What caused special offence was its recognition of the right of women to preach and baptize. There is no doubt that the present differs very considerably from the original form of the *Acta*, but even now its Gnostic origin is betrayed in several features which it still retains—for example, the rejection of marriage. For the text, see the *Acta Apost. Apocr.* of Tischendorf, who in the Prolegomena gives a large body of evidence for its great antiquity. A translation is given in the *Ante-Nicene Christian Library.*

THEFT is, in modern legal systems, universally treated as a crime, but the conception of theft as a crime is not one belonging to the earliest stage of law. To its latest period Roman law regarded theft (*furtum*) as a delict *prima facie* pursued by a civil remedy,—the *actio furti* for a penalty, the *vindicatio* or *condictio* for the stolen property itself or its value. In later times, no doubt, a criminal remedy to meet the graver crimes gradually grew up by the side of the civil, and in the time of Justinian the criminal remedy, where it existed, took precedence of the civil (*Cod.*, iii. 8, 4). But to the last criminal proceedings could only be taken in serious cases, *e.g.*, against stealers of cattle (*abigei*) or the clothes of bathers (*balnearii*). The punishment was death, banishment, or labor in the mines or on public works. In the main the Roman law of theft coincides with the English law. The definition as given in the *Institutes* (iv. 1, 1) is "furtum est contrectatio rei fraudulosa, vel ipsius rei, vel etiam ejus usus possessionisve," to which the *Digest* (xlvii. 2, 1, 3) adds "lucri faciendi gratia." The earliest English definition, that of Bracton (150*b*), runs thus: "furtum est secundum leges contrectatio rei alienæ fraudulenta cum animo furandi invito illo domino cujus res illa fuerit." Bracton omits the "lucri faciendi gratia" of the Roman definition, because in English law the motive is immaterial,[1] and the "usus ejus possessionisve," because the definition includes an intent to deprive the owner of his property permanently. The "animo furandi" and "invito domino" of Bracton's definition are expansions for the sake of greater clearness. They seem to have been implied in Roman law. *Furtum* is on the whole a more comprehensive term than theft. This difference no doubt arises from the tendency to extend the bounds of a delict and to limit the bounds of a crime. Thus it was *furtum* (but it would not be theft at English common law) to use a deposit of pledge contrary to the wishes of the owner, to retain goods found, or to steal a human being, such as a slave or *filius familias* (a special form of *furtum* called *plagium*). The latter would be in English law an abduction under certain circumstances, but not a theft. On the other hand, one of two married persons could not commit *furtum* as against the other, but theft may be so committed in England since recent legislation. As a *furtum* was merely a delict, the *obligatio ex delicto* could be extinguished by agreement between the parties; it will be seen that this cannot be done in England. In another direction English law is more considerate of the rights of third parties than was Roman. As will appear hereafter, the thief can give a good title to stolen goods; in Roman law he could not do so, except in the single case of a *hereditas* acquired by *usucapio*. The development of the law of *furtum* at Rome is historically interesting, for even in its latest period is found a relic of one of the most primitive theories of law adopted by courts of justice: "They took as their guide the measure of vengeance likely to be exacted by an aggrieved person under the circumstances of the case" (Maine, *Ancient Law*, ch. x.). This explains the reason of the division of *furtum* into *manifestum* and *nec manifestum*. The manifest thief was one taken red-handed,—"taken with the manner," in the language of old English law. The Twelve Tables denounced the punishment of death against the manifest thief, for that would be the penalty demanded by the indignant owner in whose place the judge stood. The severity of this penalty was afterwards mitigated by the prætor, who substituted for it the payment of quadruple the value of the thing stolen. The same penalty was also given by the prætor in case of theft from a fire or a wreck, or of prevention of search. No doubt the object of this large penalty was to induce injured persons to refrain from taking the law into their own hands. The Twelve Tables mulcted the non-manifest thief in double the value of the thing stolen. The actions for penalties were in addition to the action for the stolen goods themselves or their value. The quadruple and double penalties still remain in the legislation of Justinian. The search for stolen goods, as it existed in the time of Gaius, was a survival of a period when the injured person was, as in the case of summons (*in jus vocatio*), his own executive officer. Such a search, by the Twelve Tables, might be conducted in the house of the supposed thief by the owner in person, naked except for a cincture, and carrying a platter in his hand, safeguards apparently against a violation of decency and against any possibility of his making a false charge by depositing some of his own property on his neighbor's premises. This mode of search became obsolete before the time of Justinian. Robbery (*bona vi rapta*) was violence added to *furtum*. By the *actio vi bonorum raptorum* quadruple the value could be recovered if the action were brought within a year, only the value if brought after the expiration of a year. The quadruple value, it is to be noted, included the stolen thing itself, so that the penalty was in effect only a triple one. It was inclusive, and not cumulative, as in *furtum*.

In England theft appears to have been very early regarded by legislators as a matter calling for special attention. The pre-Conquest compilations of laws are full of provisions on the subject. It is noticeable that the earlier ones appear to regard theft as a delict which may be compounded for by payment. Considerable distinctions of person are made, both in regard to the owner and the thief. Thus, by the laws of Ethelbert, if a freeman stole from the king he was to restore ninefold, if from a freeman or from a dwelling threefold. If a theow stole, he had only to make a twofold reparation. In the laws of Alfred ordinary theft was still only civil, but he who stole in a church was punished by the loss of his hand. The laws of Ina named as the penalty death or redemption according to the wer-gild of the thief. By the same laws the thief might be slain if he fled or resisted. Gradually the severity of the punishment increased. By the laws of Athelstan death in a very cruel form was inflicted. At a later date the *Leges Henrici Primi* placed a thief in the king's mercy, and his lands were forfeited. Putting out the eyes and other kinds of mutilation were sometimes the punishment. The principle of severity continued down to the present century, and until 1827 theft of certain kinds remained capital. Both before and after the Conquest local jurisdiction over thieves was a common franchise of lords of manors, attended with some of the advantages of modern summary jurisdiction. It might be exercised either over thieves who committed a theft or were apprehended within the lordship (*infangthef*), or over those inhabitants of the lordship who were apprehended elsewhere (*outfangthef*). Either or both franchises might be enjoyed by grant or prescription. As lately as 1 Ph. and M. c. 15 infangthef and outfangthef were confirmed to the lords marchers of Wales. An analogous franchise was *theam*, or the right of calling upon the holder of stolen goods to vouch to warranty, *i.e.*, to name from whom he received them. In the old law of theft there were to be found two interesting survivals of the primitive legal notions which were found in Roman law. Up to a comparatively recent date a distinction analogous to that between *furtum manifestum* and *nec manifestum* was of importance in English criminal practice. The thief "taken with the manner" was by the Statute of Westminster the First not to be admitted to bail (see *Letters of Junius*, lxviii.). In modern procedure the probable guilt or innocence of the accused is not so much to be considered in a question of bail as the probability of his appearance at the trial. The other matter worthy of notice is the old pursuit (*secta*) by hue and cry. In the pre-Conquest codes the owner was generally allowed to take the law into his own hand, as in early Roman law, and get back his goods by force if he could, no doubt with the assistance of his neighbors where possible. From this arose the later development of the hue and cry, as the recognized means of pursuing a thief. The Statutes of Westminster the First and of *De officio coronatoris* enacted that all men should be ready to pursue and arrest felons, and ten years later the Statute of Winchester (1285) enforced upon all, the duty of keeping arms for the purpose of following the hue and cry. It also made the hundred liable for thefts with violence committed in it, an adoption no doubt in feudal law of the old pre-Conquest liability of the frithborg. As justice became more settled, the hue and cry was regulated more and more by law, and lost much of its old natural simplicity. This led to its gradually becoming obsolete, though the Statutes of Westminster the First and *De officio coronatoris* are still nominally law as far as they relate to the hue and cry. The Statute of Winchester as to the liability of the hundred was repealed in 1827.

---

[1] Thus destruction of a letter by a servant with a view of suppressing inquiries into her character, makes the servant guilty of larceny in English law.

The term theft in modern English law is sometimes used as a synonym of larceny, sometimes in a more comprehensive sense. In the latter sense it is used by Mr. Justice Stephen, who defines it as "the act of dealing from any motive whatever, unlawfully and without claim of right, with anything capable of being stolen, in any of the ways in which theft can be committed" (for which see § 296–300), "with the intention of permanently converting that thing to the use of any person other than the general or special owner thereof" (*Digest of the Criminal Law*, § 295). In this broader sense the term applies to all cases of depriving another of his property, whether by removing or withholding it. It thus includes larceny, robbery, cheating, embezzlement, and breach of trust. Embezzlement is a statutory crime created as a separate form of offence in the last century (see vol. viii. p. 147). The difference between larceny and embezzlement turns mainly on the fact of the master's being in actual or constructive possession of the stolen property (see POSSESSION). Fraudulent breach of trust was not made a specific offence until 1857 (see TRUST).

Larceny (a corruption of *latrocinium*), or theft proper, was felony at common law. The common law of larceny has been affected by numerous statutes, the main object of legislation being to bring within the law of larceny offences which were not larcenies at common law, either because they were thefts of things of which there could be no larceny at common law, *e.g.*, beasts *feræ naturæ*, title deeds or choses in action, or because the common law regarded them merely as delicts for which the remedy was by civil action, *e.g.*, fraudulent breaches of trust. The earliest Act in the statutes of the realm dealing with larceny appears to be the *Carta Forestæ* of 1225, by which fine or imprisonment was inflicted for stealing the king's deer. The next Act appears to be the Statute of Westminster the First (1275), dealing again with stealing deer. From this it seems as though the beginning of legislation on the subject was for the purpose of protecting the chases and parks of the king and the nobility. An immense mass of the old Acts will be found named in the repealing Act of 1827, 7 and 8 Geo. IV. c. 27. An Act of the same date, 7 and 8 Geo. IV. c. 29, removed the old distinction between grand and petit larceny.[1] The former was theft of goods above the value of twelve pence [24 cts.] in the house of the owner, not from the person, or by night, and was a capital crime. It was petit larceny where the value was twelve pence or under, the punishment being imprisonment or whipping. The gradual depreciation in the value of money afforded good ground for Sir Henry Spelman's sarcasm that, while everything else became dearer, the life of man became continually cheaper. The distinction between grand and petit larceny first appears in statute law in the Statute of Westminster the First, c. 15, but it was not created for the first time by that statute. It is found in some of the pre-Conquest codes, as that of Athelstan, and it is recognized in the *Leges Henrici Primi*. A distinction between simple and compound larceny is still found in the books. The latter is larceny accompanied by circumstances of aggravation, as that it is in a dwelling-house or from the person. The law of larceny is now contained chiefly in the Larceny Act, 1861, 24 and 25 Vict. c. 96 (which extends to England and Ireland), a comprehensive enactment including larceny, embezzlement, fraud by bailees, agents, bankers, factors, and trustees, sacrilege, burglary, housebreaking, robbery, obtaining money by threats or by false pretences, and receiving stolen goods, and prescribing procedure, both civil and criminal. There are still, however, some earlier Acts in force dealing with special cases of larceny, such as 33 Hen. VIII. c. 12, as to stealing the goods of the king, and the Game, Post-Office, and Merchant Shipping Acts. Later Acts provided for larceny by a partner of partnership property (31 and 32 Vict. c. 116), and by a husband or wife of the property of the other (45 and 46 Vict. c. 75). Proceeding against persons subject to naval or military law depend upon the Naval Discipline Act, 1866, and the Army Act, 1881. There are several Acts both before and after 1861, directing how the property is to be laid in indictments for stealing the goods of counties, friendly societies, trades unions, etc. The principal conditions which must exist in order to constitute larceny are these: (1) there must be an actual taking into the possession of the thief, though the smallest removal is sufficient; (2) there must be an intent to deprive the owner of his property for an indefinite period, and to assume the entire dominion over it, an intent often described in Bracton's words as *animus furandi*; (3) this intent must exist at the time of taking; (4) the thing taken must be one capable of larceny either at common law or by statute. One or two cases falling under the law of larceny are of special interest. It was held more than once that a servant taking corn for the purpose of feeding his master's horses, but without any intention of applying it for his own benefit, was guilty of larceny. To remedy this hardship, 26 and 27 Vict. c. 103 was passed to declare such an act not to be felony. The case of appropriation of goods which have been found has led to some difficulty. It now seems to be the law that in order to constitute a larceny of lost goods there must be a felonious intent at the time of finding, that is, an intent to deprive the owner of them, coupled with reasonable means at the same time of knowing the owner. The mere retention of the goods when the owner has become known to the finder does not make the retention criminal. Larceny of money may be committed when the money is paid by mistake, if the prisoner took it *animo furandi*. In two recent cases the question was argued before a very full Court for Crown Cases Reserved, and in each case there was a striking difference of opinion. In Reg. *v.* Middleton, *Law Rep.*, 2 Crown Cases Reserved, 38, the prisoner, a depositor in a post-office savings bank, received by the mistake of the clerk a larger sum than he was entitled to. The jury found that he had the *animus furandi* at the time of taking the money, and that he knew it to be the money of the postmaster-general. The majority of the court held it to be larceny. In a case in 1885 (Reg. *v.* Ashwell, *Law Rep.*, 16 Queen's Bench Division, 190), where the prosecutor gave the prisoner a sovereign believing it to be a shilling, and the prisoner took it under that belief, but afterwards discovered its value and retained it, the court was equally divided as to whether the prisoner was guilty of larceny at common law, but held that he was not guilty of larceny as a bailee. The procedure in prosecutions for larceny has been considerably affected by recent legislation. The inconveniences of the common-law rules of interpretation of indictments led to certain amendments of the law, now contained in the Larceny Act, for the purpose of avoiding the frequent failures of justice owing to the strictness with which indictments were construed. Three larcenies of property of the same person within six months may now be charged in one indictment. On an indictment for larceny the prisoner may be found guilty of embezzlement, and *vice versa*; and if the prisoner be indicted for obtaining goods by false pretences, and the offence turn out to be larceny, he is not entitled to be acquitted of the misdemeanor. A count for receiving may be joined with the count for stealing. In many cases it is unnecessary to allege or prove ownership of the property the subject of the indictment. The Act also contains numerous provisions as to venue and the apprehension of offenders. In another direction the powers of courts of SUMMARY JURISDICTION (*q.v.*) have been extended, in the case of charges of larceny, embezzlement, and receiving stolen goods, against children and young persons and against adults pleading guilty or waiving their right to trial by jury. The maximum punishment for larceny is fourteen years' penal servitude, but this can only be inflicted in certain exceptional cases, such as horse or cattle stealing and larceny by a servant or a person in the service of the crown or the police. The extreme punishment for simple larceny after a previous conviction for felony is ten years' penal servitude. Whipping may be part of the sentence on boys under sixteen.

---

[1] This provision was most unnecessarily repeated in the Larceny Act of 1861.

Robbery is larceny accompanied by violence or threatened violence. Whether obtaining money by threats to accuse of crime was robbery at common law was open to some doubt. It is now a specific offence under the Larceny Act, punishable by penal servitude for life. Whipping may be added as part of the sentence for robbery by 26 and 27 Vict. c. 44.

Cheating is either a common-law or statutory offence. An indictment for cheating at common law is now of comparatively rare occurrence. The statutory crime of obtaining money by false pretences is the form in which the offence generally presents itself. Like embezzlement, this offence dates as a statutory crime from the last century. It now depends upon the Larceny Act. A false pretence is defined by Mr. Justice Stephens as "a false representation made either by words, by writing, or by conduct that some fact or facts existed" (*Digest of the Criminal Law*, § 330). The principal points to notice are that the false pretence must be of an existing fact (*e.g.*, it was held not to be a false pretence to promise to pay for goods on delivery), and that property must have been actually obtained by the false pretence. The broad distinction between this offence and larceny is that in the former the owner intends to part with his property, in the latter he does not. By 22 and 23 Vict. c. 17, no indictment for obtaining money by false pretences is to be presented or found by the grand jury unless the defendant has been committed for trial or the indictment is authorized in one of the ways mentioned in the Act. The maximum punishment for the common-law offence is fine or imprisonment at discretion, for the statutory five years' penal servitude.

Stolen Goods.—The owner of the goods stolen has an action against the thief for the goods or their value. How far he is entitled to pursue his civil right to the exclusion of criminal prosecution does not seem very clear upon the authorities. One of the latest statements of the law was that of Mr. Justice Watkin Williams: "It has been said that the true principle of the common law is that there is neither a merger of the civil right, nor is it a strict condition precedent to such right that there shall have been a prosecution of the felon, but that there is a duty imposed upon the injured person not to resort to the prosecution of his private suit to the neglect and exclusion of the vindication of the public law; in my opinion this view is the correct one" (Midland Insurance Company *v.* Smith, *Law Rep.*, 6 Queen's Bench Division, 568). Dealing with stolen goods by persons other than the thief may affect the rights of such persons either criminally or civilly. Two varieties of crime arise from such dealings. (1) Receiving stolen goods knowing them to have been stolen, a misdemeanor at common law, is by the Larceny Act a felony punishable by penal servitude for fourteen years where the theft amounts to felony, a misdemeanor punishable by penal servitude for seven years where the theft is a misdemeanor, as in obtaining goods by false pretences. Recent possession of stolen property may, according to circumstances, support the presumption that the prisoner is a thief or that he is a receiver. The Prevention of Crime Act, 1871, made important changes in the law of evidence in charges of receiving. It allows, under proper safeguards, evidence to be given in the course of the trial of the finding of other stolen property in the possession of the accused, and of a previous conviction for any offence involving fraud and dishonesty. (2) Compounding theft, or theftbote, that is, taking back stolen goods or receiving compensation on condition of not prosecuting, is a misdemeanor at common law. It need not necessarily be committed by the owner of the goods. Under the Larceny Act it is a felony punishable by seven years' penal servitude to corruptly take money or reward for helping to recover stolen goods without using all due diligence to bring the offender to trial. By the same Act, to advertise or print or publish any advertisement offering a reward for the return of stolen goods, and using any words purporting that no questions will be asked, etc., renders the offender liable to a penalty of £50 [$243]. This penalty must, by 33 and 34 Vict. c. 65, be sued for within six months, and the assent of the attorney-general is necessary. Various Acts provide for the liabilities of pawnbrokers, publicans, marine-store dealers, and others into whose possession stolen goods come. Search for stolen goods can only be undertaken by a police officer under the protection of a search warrant. The law as to stolen goods, as far as it affects the civil rights and liabilities of the owner and third parties, is shortly as follows: As a general rule a purchaser takes goods subject to any infirmities of title. The property in money, bank-notes, and negotiable instruments passes by delivery, and a person taking any of these *bona fide* and for value is entitled to retain it as against a former owner from whom it may have been stolen. In the case of other goods, a *bona fide* purchaser of stolen goods in market overt (see SALE) obtains a good title (except as against the crown), provided that the thief has not been convicted. After conviction of the thief the property revests in the owner, and the court before which the thief was convicted may order restitution, except in the cases specially mentioned in the Larceny Act, *i.e.*, the *bona fide* discharge or transfer of a security for value without notice and the fraudulent dealing by a trustee, banker, etc., with goods and documents of title to goods entrusted to him. After conviction of the thief the goods must be recovered from the person in whose hands they are at the time of the conviction, for any sales and resales, if the first sale was in market overt, are good until conviction of the thief. If the goods were obtained by false pretences and not by larceny, the question then is whether the property in the goods has passed or not, and the answer to this question depends upon the nature of the false pretences employed. If the vendee obtains possession of goods with the intention by the vendor to transfer both the property and the possession, the property vests in the vendee until the vendor has done some act to disaffirm the transaction. But if there was never any such intention,—if, for instance, the vendor delivers the goods to A. B. under the belief that he is C. D., —the property does not vest in the transferee, and the owner may recover the goods even from a *bona fide* purchaser.[1]

Scotland.—There is a vast quantity of Acts of the Scottish parliament dealing with theft. The general policy of the Acts was to make thefts what were not thefts at common law, *e.g.*, stealing fruit, dogs, hawks, or deer, and to extend the remedies, *e.g.*, by giving the justiciar authority throughout the kingdom, by making the master in the case of theft by the servant liable to give the latter up to justice, or by allowing the use of firearms against thieves. The general result of legislation in England and Scotland has been to assimilate the law of theft in both kingdoms. As a rule, what would be theft in one would be theft in the other. There can be theft of children in Scots as in Roman law, under the name of *plagium*. The crime of stouthrief is robbery accompanied by exceptional violence. The English receiving stolen goods and obtaining money under false pretences are represented by the reset and fraud of Scots law. Theftbote or *redemptio furti* appears in legislation as early as the assizes of King William, c. 2. The offender was there subjected to the ordeal of water if convicted on the oath of three witnesses, to be immediately hanged if the oath of three *seniores* were added. The offence was made punishable by 1436, c. 1, 1515, c. 2, and appears still to be a crime. Blackmailing, under that name, was forbidden by 1567, c. 27. There is no consolidation Act for Scotland like the Larceny Act for England and Ireland, but various Acts are in force dealing with specific offences or with procedure. Thus 7 Anne c. 21, § 7, makes theft by landed men no longer treason, as it had previously been. 4 Geo. II. c. 32 deals with theft of lead, etc., fixed to houses, 21 Geo. II. c. 34 with the admissibility of an accomplice as witness in a charge of cattle stealing, 51 Geo. III. c. 41 with theft of linen, etc. The most important Act relating to procedure is 31 and 32 Vict. c. 95, § 12, by which a previous conviction for theft may be libelled and proved as aggravation of robbery, and a previous conviction for robbery as aggravation of theft. Stolen goods are always taken subject to the inherent *vitium reale* of their acquisition, and the true owner may recover them from any one in whose possession they are. The protection given by market overt is unknown in Scotland. See Macdonald, *Criminal Law*, p. 18.

---

[1] For the Roman and English law, see, besides the authorities cited, Hunter, *Roman Law;* Muirhead, *Roman Law;* 4 Stephen, *Commentaries*, pt. vi. chap. v.; 8 Stephen, *Hist. of the Criminal Law*, chap. xxviii.

United States.—The law depends almost entirely upon State legislation, and is in general accordance with that of England. The only Acts of Congress bearing on the subject deal with theft in the army and navy, and with theft and receiving on the high seas or in any place under the exclusive jurisdiction of the United States. The doctrine of market overt is not acknowledged by any State. (J. W †.)

THEISM.

Meanings of the word theism. Its generic sense.

THE term theism has three significations. In its widest acceptation its object is the divine, whether regarded as personal or impersonal, as one being or as a number of beings. In this sense theism is coextensive with religion and worship, includes all forms of polytheism and of pantheism, as well as all varieties of monotheism, and so may be said to denote the genus of which polytheism, pantheism, and monotheism are species. The conception of the Divine, in its utmost abstractness and generality, is, however, so vague that it may reasonably be doubted if the forms of theism, thus understood, can be distributed into strictly logical and natural species, with definitions at once perfectly distinct in themselves and exactly accordant with phenomena. It may seem as if polytheism and monotheism must, by arithmetical necessity, be exclusive of each other and exhaustive of theism; but this is not so. Pantheism may clearly partake of the nature of both, and has been sometimes extravagantly polytheistic, sometimes only doubtfully distinguishable from fully developed monotheism. Probably few, if any, polytheistic religions are purely polytheistic, or, in other words, do not imply in some mode and measure the unity as well as the plurality of the Divine. Christian monotheism answers to a formal definition of monotheism only inasmuch as it holds to the unity of the Godhead, but contravenes it inasmuch as it holds that in the one Godhead there are three Divine persons, each God.

Its negatives.

The complete negation of theism in its generic sense is atheism—the denial of the existence or of the knowability of the Divine. It is only in modern times that the word atheism has acquired this meaning, only in recent times that it has come to be exclusively employed with this meaning. The Greeks meant by it simply disbelief in the Greek gods. The early Christians were called atheists because they refused to acknowedge the Pagan deities. Protestants have been charged by Roman Catholics and Roman Catholics by Protestants with atheism. Throughout even the 18th century the word was used in an extremely loose manner, and often affixed to systems by which the existence and agency of God were unequivocally recognized. Atheism, in the sense now generally admitted to be alone appropriate, may be of three species,—namely, denial of the existence of the Divine, denial that the Divine has been shown to exist, and denial that it can be known that the Divine exists. The first species has been called *dogmatic atheism*, the second *critical atheism;* and the third has been designated, and may conveniently be designated, *religious agnosticism*. Agnosticism *per se* should not be identified with atheism or with any of its forms. The term antitheism has been used by some theologians, *e.g.*, Chalmers and Foster, as equivalent to dogmatic atheism; but it may with much more practical advantage be employed to denote all systems of belief opposed to theism, either in the generic sense already indicated, or in the specific sense of monotheism. Understood in this latter mode, it is much more comprehensive than the term atheism. Polytheism and pantheism are alike antitheistic theories, although on different grounds; while only those theories which deny that there is evidence for belief even in the existence of any god, any divine being, are atheistic.

Theism ordinarily equivalent to monotheism.

It is somewhat remarkable that the term theism by itself never occurs in its etymological and generic sense, never means as a separate word what it means in the compounds atheism, polytheism, pantheism, and monotheism. Ordinarily it is identified with monotheism, and consequently opposed to polytheism and to pantheism, as well as to atheism. Whereas polytheism acknowledges a plurality of finite gods, theism as monotheism acknowledges only one absolute infinite God. Whereas pantheism regards all finite things as merely aspects, modifications, or parts of one eternal self-existent being—all material objects and all particular minds are necessarily derived from a single infinite substance,—and thus combines, in its conception of the Divine, monism and determinism, theism as monotheism, while accepting monism, rejects determinism, and attributes to the Divine all that is essentially implied in free personal existence and agency. Pantheism is, however, wonderfully protean, and rarely conforms to its ideal; hence the systems called pantheistic are seldom purely pantheistic, and are often more monotheistic than pantheistic.

Theism and deism.

Sometimes the term theism is employed in a still more special sense, namely, to denote one of two kinds of monotheism, the other kind being *deism*. Although *deus* and *theos* are equivalent, deism has come to be distinguished from theism. The former word first appeared in the 16th century, when it was used to designate antitrinitarian opinions. In the 17th century it came to be applied to the view that the light of nature is the only light in which man can know God, no special revelation having been given to the human race. Dr. Samuel Clarke, in the Boyle Lectures preached in 1705, distributed deists into four classes. The first class "pretend to believe the existence of an eternal, infinite, independent, intelligent being, and, to avoid the name of Epicurean atheists, teach also that this supreme being made the world; though at the same time they agree with the Epicureans in this that they fancy God does not at all concern Himself in the government of the world, nor has any regard to, or care of, what is done therein." The second class acknowledge not only that God made all things, but that He sustains and governs them, yet deny that He has any regard in His government to moral distinctions, these being merely the products of human will and law. The third class believe in the being, natural attributes, providence, and to some extent in the moral attributes and government of God, but deny the immortality of the soul and a future state of rewards and punishments. The fourth class acknowledge the being, natural and moral perfections, and providence of God, as also the immortality of the soul and a future state of rewards and punishments, yet profess to believe only what is discoverable by the light of nature, without believing any divine revelation (Clarke, *On the Attributes*, pp. 140–153, ed. 1823). This division is not an exact classification, nor does it rest on any precise definition of deism, but it, with substantial accuracy, discriminates and grades the varieties of English deism. Clarke did not contrast deism with theism, or even employ the latter word. His contemporary Lord Shaftesbury, on the other hand, generally used the term theism, yet only as synonymous with deism, and with a protest against either being opposed to revelation (*Characteristics*, vol. ii. p. 209, ed. 1727). Kant, in his *Kritik der reinen Vernunft*, explicitly distinguished and opposed deism and theism, but in a very peculiar manner. "The person who believes in a transcendental theology alone is termed a *deist;* he who acknowledges the possibility of a natural theology also, a *theist*. The former admits that we can cognize by pure reason alone the existence of a supreme being, but at the same time maintains that our conception of this being is purely transcendental, and that all that we can say of it is that it possesses all reality, without being able to define it more closely. The second asserts that reason is capable of presenting us, from the analogy of nature, with a more definite conception of this being, and that its operations, as the cause of all things, are the results of intelligence and free will. The former regards the supreme being as *the cause of the world*,—whether by the necessity of his nature, or as a free agent, is left undetermined; the latter considers this being as the *author of the world*" (*Werke*, ii. 491, edited by Rosenkranz, Meiklejohn's tr., 387–8). The account here given of deism seems neither self-consistent nor intelligible, and applies, equally well or equally ill, to every system—atheistic, agnostic, pantheistic, idealistic, or materialistic—which admits the existence but not the intelligence or personality of an *Urwesen*, eternal being, or first cause; and the account of theism excludes all reference to revelation, and applies to every form of what has been regarded as deism. In recent theology deism has generally come to be regarded as, in common with theism, holding in opposition to atheism that there is a God, and in opposition to pantheism that God is distinct from the world, but as differing from theism in maintaining that God is separate from the world, having endowed it with self-sustaining and self-acting powers, and then abandoned it to itself. This distinction is real, and perhaps the best attainable. At the same time many called deists must be admitted not to have taught deism thus understood; for example, most of the "English deists" did not deny that God was present and active in the laws of nature, but merely denied that He worked otherwise than through natural laws. If by deism he meant belief in a personal God who acts only through natural laws, and by theism belief in a personal God who acts both through natural laws and by special interventions, this distinction also is real, and may be useful. The chief objection to it is that deism when so contrasted with theism does not denote, or even include, what theologians have generally agreed to call by the name.

The present article will treat specially of theism in the sense of monotheism, but not to the exclusion of the relations between theism thus understood and theism in other acceptations.

Nature of primeval religion.

Monotheism has been very generally assumed to have been the primitive religion. Lord Herbert, Cudworth, and others have elaborately defended this opinion in the past, and it still finds learned advocates. On the other hand, the vast majority of recent anthropologists hold that religion originated in some rude phase of polytheism, and that monotheism has been everywhere preceded by polytheism. Schelling, Max Müller, and Hartmann have maintained that the starting-point of religion was *henotheism*, and imperfect kind of monotheism, in which God was thought of as one, only because others had not yet presented themselves to the mind,—a monotheism of which polytheism was not the contradiction, but the natural development. Pantheism has also been frequently represented to be the earliest phase of religion. All these representations, however, will be found on examination to be very conjectural. The present state of our knowledge does not warrant our holding any view regarding the nature of primeval religion as established. The data which carry us farthest in our search for the historical origin of religion are undoubtedly the names expressive of the Divine which have been preserved in the most ancient languages. They show us how men conceived of the Divinity long before the erection of the oldest monuments or the inscription of the oldest records. Language is much older than any of the statements in language. But language by no means carries us back to primitive man, or even to the historical origin of the idea of deity. The Egyptian word *nutar* and the names of the Egyptian gods found in the oldest Egyptian inscriptions prove that at a date long before the Egyptians wrote history, or are known to have worshipped animals or ancestors, they conceived of Divinity as power, and their deities as great cosmic forces; but, as that word and these names cannot be shown to have belonged to man's primitive speech, they cannot show what was man's primitive religious belief, and do not disprove that the forefathers of the people who first used them may have had some lower and ruder conception of the Divine than that which they convey. There are, according to Dr. Legge, no words in the Chinese language known to be older than *ti, t'ien, shang-ti*, and these words are good historical evidence that the Chinese conceived of the Divine, thousands of years before the Christian era, as a universal ruling power, comprehending the visible heavens, and an invisible infinite, omnipresent force, manifested in the azure of the firmament, possessed so far of intellectual and moral qualities, and working towards ethical ends. There is no evidence that when the Chinese first used these words they worshipped fetiches, but neither is there evidence to the contrary, and even if there were it would not disprove that the ancestors of the Chinese had passed through an era of fetichism. All members of the Semitic family of languages have the word *El*, or some modification of it, to denote deity, and hence we may conclude that the Semites had the word in this sense before they separated and became distinct peoples, but not that the idea of God originated when the word was first thus employed. All members of the Teutonic group of languages have the word *God*, or some slightly modified form thereof, and all members of the Slavic group of languages have the word *Bog*, or some modification thereof, to express the same conception: it does not follow that either Teutons or Slavs had no idea of deity until the former so applied the word *God*, and the latter so applied the word *Bog*. Both Teutons and Slavs are Aryans, and there is an older Aryan term for deity than either *God* or *Bog*. The Sanscrit *deva*, the Latin *deus*, and the northern *ti, tivar*, are forms of a word which must have been used by the Aryans to express their idea of the Divine when, in a prehistoric age, they lived to-

Evidence of language inadequate.

gether in their original home; but we are not entitled to infer that even that prehistoric Aryan term is the oldest word for deity. It may not be older than the primitive Semitic word or the primitive Turanian word, or the *nutar* of the Egyptians, or the *t'ien* of the Chinese, or the earliest designations for the Divine in the earliest African and American languages. And there may have been Divine names older than any of these. The science of language has been able to reconstruct in part a prehistoric Aryan language, and may similarly be able to reconstruct a prehistoric Semitic language, a prehistoric Turanian, and perhaps a prehistoric Hamitic language. Should it proceed thus far it will probably perceive that all these prehistoric languages arose out of a still earlier prehistoric language in which also were words expressing ideas of the Divine. There may be many strata of language buried too deep for human excavation in the abysses of unrecorded time. By no possibility, therefore, can the analysis of existing languages disclose to us the oldest name for deity or the historical origin of the idea of deity. Geology shows the vast antiquity of man, and nothing proves that he may not have been awed or comforted by thoughts of the Divine ages before the invention of the oldest Aryan or Semitic words. It is merest conjecture to assign the formation of the conception of deity to the dawn of historic time. Between primitive speech, primitive religion, the primitive condition of man, and the little streak of light called human history there stretches an immeasurable expanse of darkness.

Evidence of book of Genesis.

The belief in primitive monotheism is generally rested on the authority of the opening chapters of Genesis. It is, however, doubtful if the appeal to them be legitimate, because doubtful if their strict historicity can be proved to those who insist on judging them merely by critical and historical criteria, or even if it can be fairly inferred from the view that they form part of a revelation. Then, although these chapters plainly teach monotheism, and represent the God whose words and acts are recorded in the Bible as no mere national God but the only true God, they do not teach, what is alone in question, that there was a primitive monotheism,—a monotheism revealed and known from the beginning. They give no warrant to the common assumption that God revealed monotheism to Adam, Noah, and others before the flood, and that the traces of monotheistic beliefs and tendencies in heathendom are derivable from the tradition of this primitive and antediluvian monotheism. The one true God is represented in Genesis as making himself known by particular words and in particular ways to Adam, but is nowhere said to have taught him that He only was God. Adam knew, of course, only one God, as there was only one God to know; but that he knew there was only one God we are not told, nor are any grounds given us even for conjecturing that he knew it. We are told that God created the heavens and earth, but not that Adam was told it, and we know too little about Adam to be able to conceive how he could have understood the statement. We are informed that he knew God—the God who manifested himself to him in particular acts, but not what general idea he formed of God—whether henotheistic, pantheistic, or monotheistic, whether definitely exclusive of polytheism or not, or in what measure anthropomorphic. It is not otherwise as regards what is reported of Noah. In fact, primitive monotheism is read into the records in Genesis only because they are read in an inaccurate and uncritical manner. If read aright, it would be seen that, while they speak much of how God acted towards man, they speak so extremely little as to what early man knew of God that the appeal to them on behalf of the hypothesis of primitive monotheism must be futile, even on the traditional view of their authorship and historicity.[1]

Evidence of history.

Early religions not monotheistic.

Egyptian religion.

It is impossible to prove historically that monotheism was the primitive religion. Were, then, the oldest known historical forms of religion monotheistic? Many maintain they were, but adequate evidence has never been adduced for the opinion. The oldest known religion is probably the Egyptian, and for at least three thousand years its history can be traced by the aid of authentic records contemporary with the facts to which they relate. Its origin, however, is not disclosed by Egyptian history, and was unknown to the Egyptians themselves. When it first appears in the light of history it has already a definite form, a character not rude and simple, but of considerable elevation and subtilty, and is complex in contents, having certain great gods, but not so many as in later times, ancestor-worship, but not so developed as in later times, and animal worship, but very little of it as compared with later times. For the opinion that its lower elements were older than the higher there is not a particle of properly historical evidence,—not a trace in the inscriptions of mere propitiation of ancestors, or of belief in the absolute divinity of kings or animals; on the contrary, ancestors are always found propitiated through prayer to some of the great gods, kings worshipped as emanations and images of the sun-god, and the divine animals adored as divine symbols and incarnations. The greater gods mentioned on the oldest tombs and in the oldest writings are comparatively few, and their mere names—Osiris, Horus, Thoth, Seb, Nut, Anubis, Apheru, Ra, Isis, Neith, Apis—conclusively prove that they were not ancient kings or deceased ancestors, but chiefly powers of nature, and especially, although not exclusively, of the heavens; yet from the earliest historical time they were regarded as not merely elemental, but as also ethical powers, working indeed visibly and physically in the aspects and agents of nature, yet in conformity to law and with intelligence and moral purpose. Wherever the powers of nature are thus worshipped as gods, the feeling that the separate powers are not all power, that the particular deities are not the whole of divinity, must be entertained and will find expression. The Egyptians had undoubtedly such a sense of the unity of the Divine from the dawn of their history, and they expressed it so strongly in various ways from a very early period that they have been pronounced monotheists not merely by theologians attached to a traditional dogma but by most eminent Egyptologists—De Rougé, Mariette, Brugsch, and Renouf. As these scholars, however, truthfully present the facts, they satisfactorily refute themselves. A religion with about a dozen great gods—distinct as regards their names, characteristics, histories, relationships, symbols, and worship—is not monotheism in the ordinary or proper sense of the term. A religion in which the Divine is viewed as merely immanent in nature, and the deities deemed physical as well as moral, elemental as well as ethical powers, is rather pantheistic than monotheistic. Further, all assertions to the effect that the unity of the Divine is most emphatically expressed in the earliest historical stages of the religion are contrary to the evidence adduced even by those who make them. To quote Patah-Hotep as a proof of the monotheism of the Egyptian religion in its oldest historical phase is as uncritical as it would be to draw Homeric theology from the dialogues of Plato. The Egyptian religion was a polytheism which implied monism; it was not monotheism, which is exclusive of polytheism. Hence, notwithstanding frequent approximations to monotheism, the general result of the development of its monistic principles was pantheism, not monotheism.

---

[1] Among works in which the hypothesis of primitive monotheism is supported, the following may be mentioned: Steuco, *De Perenni Philosophia*, 1540; Herbert, *De Religione Gentilium*, 1645; Gale, *Court of the Gentiles*, 1669-78; Cudworth, *True Intellectual System*, 1678; Bryant, *Ancient Mythology*, 1774-76; Creuzer, *Symbolik u. Mythologie*, 1819-21; De Bonald, *Législation Primitive*, 1819; Lüken, *Traditionen des Menschengeschlechts*, 1856; Gladstone, *Homer and the Homeric Age*, 1860; Ebrard, *Apologetik*, pt. ii., 1875; Zöckler, *Lehre vom Urstand des Menschen*, 1880; Cook, *Origins of Religion and Language*, 1884; Rawlinson, *Early Prevalence of Monotheistic Beliefs* (No. 11 of Present Day Tracts).

Chinese religion.

As to the ancient Chinese religion, Dr. Legge easily shows that Prof. Tiele's description of it as "a purified and organized worship of spirits, with a predominant fetichist tendency," has no historical warrant, but he fails completely to substantiate his own view, namely, that it was a strict and proper monotheism. The names T'ien and Ti afford no evidence that the early Chinese fathers regarded deity as truly and properly spiritual and personal. It is not in the most ancient Chinese writings that spirituality and personality are ascribed to T'ien, and such ascriptions are exceptional in Chinese writings of any date. The great development of ancestor worship in China has been largely due to the impersonal character of T'ien.

Semitic religions.

The arguments which have been adduced in support of the hypothesis of a primitive Semitic monotheism are also insufficient. M. Renan's belief in a monotheistic instinct peculiar to the Semitic race has been so often and so convincingly shown to be contradicted both by history and psychology that another refutation of it might well be regarded as a mere slaying of the slain. Divine names like El, Baal, Adon, and Melech, being the oldest terms in the Semitic languages expressive of the Divinity, and having been retained through all the changes and perversions of Semitic religion, have often been maintained to imply that primitive Semitic belief was monotheistic. But in reality, Baal, Melech, and Adon were not names originally, or indeed at any time, given to the one Supreme God, or exclusively to any particular God; on the contrary, they were titles applicable to many different gods.

Aryan religions.

The oldest historical form of Aryan religion—the form in which the Vedas present it—is designated by Max Müller henotheism, in opposition to the organized anthropomorphic polytheism to which he restricts the term polytheism, but henotheism thus understood includes polytheism in its wider and more ordinary acceptation, while it excludes monotheism properly so called. The oldest known form of Aryan religion was indubitably polytheistic in the sense of being the worship of various nature-deities; and everything approximating to monotheism in India, Persia, Greece, and other Aryan-peopled lands was the product of later and more advanced thought. The assertion that history everywhere or even anywhere shows religious belief to have commenced with monotheism is not only unsupported by evidence, but contrary to evidence.[1]

Early religions not mere polytheisms.

While the oldest known religions of the world were thus not forms of monotheism, neither were they mere polytheisms, wholly devoid of monistic and monotheistic germs and tendencies. The Chinese religion, indeed, can hardly be said to have been at any period a polytheism, the Chinese people no more regarding spirits and deceased ancestors as gods than Roman Catholics so regard angels and saints. They have throughout their whole known history explicitly and clearly acknowledged the unity of the Divine—the uniqueness of T'ien (Ti, Shang-Ti). Had they in like manner acknowledged the spirituality, personality, transcendence of the Divine, their monotheism would have been indubitable. Then, even in those ancient religions, where a plurality of deities is apparent, a sense of the unity of the Divine is notwithstanding implied, and in the course of their development comes to expression in various ways. It could not be otherwise, for in these religions the divine powers (deities) are also powers of nature, and hence sprung from and participant in a mysterious common nature, an ultimate and universal agency which is at once the source of physical and divine existences and forces. Neither nature-deities nor powers of nature are ever conceived of, or indeed can be conceived of, as intirely distinct and independent. The lowest forms of polytheism, such as fetichism and animism, have no more marked characteristic than the indefiniteness of their idea of the Divine and the imperfect individualization of their deities. In the highest forms of nature-worship, *e.g.*, the Vedic, Egyptian, and Babylonian-Assyrian, the same trait is perceptible. This implicit monism of nature-worship may, through the action of various causes, come to explicit utterance in diverse modes, and has in fact done so, with the result that even in the oldest known polytheisms are to be found remarkable approximations to monotheism. One form of approximation was henotheism. When worship is ardent and earnest the particular god worshipped is apt to have ascribed to him the attributes, as it were, of all the gods—an almost absolute and exclusive godhead. Max Müller has shown how prominent a phenomenon henotheism is in the Vedas. Page Renouf has shown that it is very conspicuous also in the ancient inscriptions and hymns of Egypt. Horus, Ra, Osiris, Amun, Knum, were severally spoken of as if each were absolute God, invested not only with distinctive divine attributes but with all divine attributes. In the religious records of Babylon and Assyria monotheistic approximations of the same kind are likewise common. Now, in themselves such monotheistic modes of expression may truly be held to be the products of passing moods of mind, not reflections of permanent conviction. But every mood of mind tends to perpetuate itself, and the enthusiasm of piety which utters itself in henotheistic praises and prayers may take abiding possession of the soul of a powerful ruler or even of the hearts of a whole class of society or of a whole people, and may seem to them to find the strongest possible confirmation in experience. We may illustrate from Assyrian religious history. Tiglath-Pileser showed a marked preference for the worship of Asshur, to him "king of all the gods," "he who rules supreme over the gods." Nebuchadnezzar, again, showed a great partiality for the god Merodach, and applied exclusively to him such magnificent titles as "the lord of all beings," "the lord of the house of the gods," "the lord of lords," "the lord of the gods," "the king of heaven and earth." Nabonidus, on the other hand, specially revered Sin, the moon-god, and represented him as "the great divinity," "the king of gods upon gods," "the chief and king of the gods of heaven and earth." A preference of this kind might arise from some merely accidental or personal cause, and be confirmed by experiences mainly individual, and yet have a vast historical influence. The devotional choice of a people must tend, however, still more than that of any monarch to the elevation of one god towards absolute godhead. It was accordingly what raised Asshur, the special national god of the Assyrians, to the head of the Babylonian-Assyrian pantheon during the Assyrian period. In a struggle of deities for supremacy the national god has an immense advantage in that he has both the piety and the patriotism of the people on his side. His rule is identified with providence; he is credited with all the victories and successes of the nation; and his power and godhead seem certified by fact and experience. The logic of events in every advancing nation combines with the essential tendencies of piety and with the growth of conscience and reason to promote belief in the unity and perfection of the Divine. The general course of providence is no more polytheistic than it is atheistic. The best exemplification of the operation of the piety of an influential class in transcending polytheism is Brahmanism. But for the impulse given by Brahmanical piety Brahmanical speculation would never have reduced the Vedic gods to manifestations of Brahma. Henotheistic forms of approximation to monotheism are not, however, the only ones. Particular gods—all of them—may be dropped out of view, and the generic thought of God alone retained. The mind and heart of the devout may be directed exclusively to the power of the powers, the God in the gods, God simply, the Divinity. The formation of names expressing Divinity in the abstract is an evidence of the existence of such a process, and names of the kind are to be found even among very rude peoples. But there are more obvious and conclusive indications. In one of the most ancient of books, for example, and probably the oldest manuscript in the world, the maxims of Patah-Hotep, a wise Egyptian prince of the fifth dynasty, God simply (*nutar*) is often spoken of without a name or any mythological characteristic, and in a way which is in itself quite monotheistic. "If any one beareth himself proudly he will be humbled by God, who maketh his strength." "If thou art a wise man, bring up thy son in the love of God." "God loveth the obedient, and hateth the disobedient." Sentences like these standing alone would be pronounced by every one monotheistic; and even when standing alongside of references to "gods" and "powers" they show that said gods and powers were not deemed by the Egyptian sage inconsistent with oneness of power and godhead or exhaustive of their fulness. In Babylonian-Assyrian religious history there are also distinct traces of the rise of the spirits of worshippers above particular deities, simply to deity. Sometimes they appear with special clearness in connections which tell of awakened and afflicted conscience, of the pressure of a sense of sin and guilt forcing on the heart, as it were, a conviction of One with whom it has to deal, of its need of the forgiveness and favor, not of this god or of that, but of God. The following passage may be cited as an instance. "O my Lord, my sins are many, my trespasses are great, and the wrath of the gods has plagued me with disease, and with sickness and sorrow. I fainted, but no one stretched forth his hand! I groaned, but no one heard! O Lord, do not abandon thy servant; in the waters of the great stream do Thou take his hand; the sins which he has committed do Thou turn to righteousness." Many parallel passages might be drawn from Hindu, Greek, and other sources. Clearness of moral perception is decidedly favorable to monotheistic belief. The practical reason contributes as well as the speculative reason, and precisely in the measure of its healthiness and vigor, to the formation of a true idea of the Divine. It was due more to their moral earnestness and insight than to their intellectual superiority that the Persians came nearer to monotheism than any other people of heathen antiquity. Ahriman was entirely evil, and, therefore, only to be hated and combated; while Ahuramazd was absolutely divine, perfectly good, and, therefore, to be supremely worshipped and obeyed. This moral dualism approached more closely to true monotheism than the later speculative monism, which placed above both Ahuramazd and Ahriman Zervanakarene, boundless time, indeterminate being, an ethically indifferent destiny. Finally, reason in striving to understand and explain the world tends towards monotheism. The mind cannot be expected to recognize the unity of God until it recognizes the unity of nature; when it sees nature to be a whole, a universe or cosmos, it cannot but form a conception of it which will be pantheistic, if the unity of substance, law, and evolution be alone acknowledged, and monotheistic if a unity of causality, rational plan, and ethical purpose be also apprehended. In the measure in which reason advances either on the path of scientific investigation or of philosophical speculation, polytheism must retreat and disappear; in the measure in which it discerns unity, order, system, moral government, indications of spiritual character and design in the world, monotheism must rise and spread. Now, in the chief progressive heathen nations reason, it can be proved, has gradually gained on imagination. Hence the polytheisms which they built up in their youth have been undermined and broken down by them in their maturity.[1]

---

[1] The view opposed in the above paragraph is that maintained in the following works (as well as those mentioned in the previous note),—De Rougé *Études sur le Rituel Funéraire*, 1860; Renouf, *Hibbert Lectures*, 1879; Brugsch, *Religion u. Mythologie d. alten Aegypter*, 1884; Legge, *Religion of the Chinese*, 1880; Renan, *Hist. des Langues Sémitiques*, also *Considérations sur le Caractère Gen. des Peuples Semitiques*, and *Nouvelles Considerations*; Pesch, *Der Gottesbegriff in den heidnischen Religionen des Alterthums*, 1886. Among the many replies to Renan, Max Müller's ("Semitic Monotheism," in *Chips*, vol. i.) and Steinthal's (in *Z. V. S. W.*, i.) specially merit to be mentioned.

Monotheistic movement in Greece.

A monotheistic movement can be clearly traced in ancient Greece. The popular religion of Greece, as it appeared in the Homeric poems, was as distinctly polytheistic and as little monotheistic as any known religion. Its gods were all finite, begotten, and thoroughly individualized beings. The need of unity was responded to only by the supremacy of Zeus, and Zeus was subject to destiny, surrounded by an aristocracy far from orderly or obedient, and participant in weakness, folly, and vice. To its eternal honor the Greek spirit, however, was not content with so inadequate a conception of the Divine, but labored to amend, enlarge, and elevate it. The poets and dramatists of Greece purified and ennobled the popular myths, and, in particular, so idealized the character and agency of Zeus as to render them accordant with a true conception of the Godhead. The Zeus of Æschylus and of Sophocles was not only not the Zeus of Homer, but was a god, belief in whom was inconsistent with belief in any of the Homeric gods. The dramatists of Greece did not assail the popular conception of Divinity, but they substituted for it one which implied that it was without warrant or excuse. They developed the germs of monotheism in the Greek religion, while leaving untouched its polytheistic assumptions and affirmations. These, however, were not only persistently undermined, but often directly attacked by the philosophers, some of whom eventually reached a reasoned knowledge of the one absolute Mind. Xenophanes, Empedocles, and Anaxagoras were among the pre-Socratic philosophers who, on grounds of reason, rejected the polytheism and anthropomorphism of the current mythology, and advocated belief in one all-perfect divine nature. Socrates, although avoiding all attacks on the popular religion calculated to weaken the popular reverence for divine things, had real faith only in the one supreme Reason, the source and end of all things; and the best representatives of later Greek philosophy were in this respect his followers. Plato attained by his dialectic a conception of God which will always deeply interest thoughtful men. God he deemed the highest object of knowledge and love, the source of all being, cognoscibility, truth, excellence, and beauty,—the One, the Good. The controversy as to whether his conception may be more correctly designated theistic or pantheistic will, perhaps, never be brought to a decisive conclusion, but in its general truth and grandeur it must be admitted far to transcend either the monotheism of the vulgar or any popular form of pantheism. Aristotle's characteristic cautiousness of judgment showed itself in the very meagreness of his theology. The representation which he gives of God hardly meets at all the demands of affection and of practical life, yet so far as it goes will be generally regarded as thoroughly reasonable. It is more unequivocally theistic than that of Plato. It sets forth God as without plurality and without parts; free from matter, contingency, change, and development; the eternal unmoved mover, whose essence is pure energy; absolute spirit, self-thinking reason, the *νοήσις νοήσεως*; the one perfect being, whose life is completely blessed, and whose likeness is the goal towards which the whole universe tends. Stoicism was originally and predominantly a materialistic or hylozoic form of pantheism; but some of its greatest representatives conceived of God in a decidedly theistic manner as the supreme moral reason. The beautiful hymn of Cleanthes to Zeus is full of the purest devotional feeling, springing from a clear sense of personal relationship to the one all-ruling personal Spirit. Greek philosophy proceeded throughout its whole course in entire independence of the popular polytheism, and was a continuous demonstration of its futility; and it largely contributed to that reasoned natural knowledge of God which must underlie all rational belief in revelation. It discerned in some measure all the chief arguments which have since been employed as theistic proofs. It failed, however, to conceive of God as truly creative, or of the universe as in its very substance the result of divine action; it failed also to make evident, even to cultured minds, the superiority of monotheism to pantheism and skepticism; and it failed especially to convert the common people to faith in one sole Deity.[1]

---

[1] The best literature relating to the subject of the preceding paragraph is indicated in the lists of books given in connection with the relevant sections in Tiele's *Outlines of the History of Religion*, and particularly in the French translation by M. Vernes. Hegel's *Philosophy of Religion*, Bunsen's *God in History*, Freeman Clarke's *Ten Great Religions*, the St. Giles *Lectures on the Faiths of the World*, still more the series of *Sacred Books of the East* and of ancient texts published under the title of *Records of the Past*, and the volumes of the *Rev. de l'Hist. des Religions*, will be found useful to those wishing to make a survey of heathen thought regarding God so far as it approximated to the theistic idea. For the conceptions of the Divine entertained by non-civilized peoples, see especially Waitz's *Anthropologie*, and Réville's *Religions des Non-Civilisés*, who both give extensive lists of literature.

Monotheism in Israel.

Israel presents us with the first example of a monotheistic nation. The controversies as to how Israel acquired this pre-eminence can only be decided by critical and historical investigations into which we cannot here enter (see ISRAEL).

Old Testament theology.

The science of Old Testament theology, giving due heed to the results of critical, historical, and exegetical research regarding the documents with which it deals, has to trace by what means and through what stages Hebrew monotheism was developed and established; and to the treatises on this science our readers must be referred. The monotheistic movement in Israel was one of continuous progress through incessant conflict until a result was reached of incalculable value to humanity. That result was a faith in God singularly comprehensive, sublime, and practical,—a faith which rested, not on speculation and reasoning, but on a conviction of God having directly revealed Himself to the spirits of men, and which, while ignoring metaphysical theorizing, ascribed to God all metaphysical as well as moral perfections; a faith which, in spite of its simplicity, so apprehended the relationship of God to nature as neither to confound them like pantheism nor to separate them like deism, but to assert both the immanence and the transcendence of the divine; a faith in a living and personal God, the almighty and sole creator, preserver, and ruler of the world; a faith, especially, in a God holy in all His ways and righteous in all His works, who was directing and guiding human affairs to a destination worthy of His own character; and, therefore, an essentially ethical, elevating, and hopeful faith. The existence of utterances in the Hebrew Scriptures which show that Hebrew faith was not always thus enlightened, and sometimes conceived of God as partial and cruel, is no reason for not acknowledging the general justice and grandeur of its representation of the Supreme.[2]

New Testament theology.

The God of the Old Testament is also the God of the New. Christ and the apostles accepted what Moses and the prophets had taught concerning God; they assigned to Him no other attributes than had already been assigned to Him. Like Moses and the prophets also they made no attempt formally to prove the existence or logically to define the nature of God, but spoke of Him either as from vision or inspiration. And yet their doctrine of God has original and peculiar features. Thus, first, the fatherhood of God was taught with incomparable distinctness and fulness by Jesus Christ,—a fatherhood not merely of natural creation or national election, but of spiritual relationship of love, sympathy, mercy, and grace for individual souls. Such fatherhood, if acknowledged at all, was only very rarely and vaguely acknowledged in heathendom, and, although not wholly absent from the Old Testament, is far from clearly and prominently there, and, indeed, is present chiefly by implication in passages which refer directly only to God's connection with the people of Israel, as an elect and covenant people; it is conspicuous and central, however, in the conception of God introduced by Christianity. Secondly, Divine fatherhood had its correlate in Divine sonship. God is represented in the New Testament as revealing His fatherhood through his Son, Jesus Christ. In Old Testament representations of Israel, the Messiah, and Wisdom, and in the Logos doctrine of Judæo-Alexandrian philosophy, some approximations to this conception of the Divine may be traced, but they fell far short of it. According to the New Testament, God is not merely infinitely exalted above the world and definitely distinguished therefrom, nor merely immanent and everywhere operative in nature, but also incarnate in Christ; and Christ is not merely "the Son of Man," essentially sharing in humanity and truly representing it before God, but also "the Son of God," essentially sharing in Divinity, and giving the fullest disclosure of it to man. The foundation of the Christian faith as laid down in the New Testament is that Christ through His unique relation as Son to the Father perfectly declared and expressed the nature and will of God in relation to human salvation. Thirdly, God is exhibited in the New Testament as the Spirit, the Holy Ghost, who dwells in the spirits of men, to work in them the will of the Father, and to conform them to the image of the Son. Only when thus exhibited can the revelation of the Divine name be regarded from the New Testament point of view as other than manifestly incomplete. Even the manifestation of God in Christ, being objective and single, must be supplemented by a manifestation which is subjective and multiple, before the one God, the one Christ, can find a place in the manifoldness of souls, the multitude of separate hearts and lives. The manifestation of the Spirit is such a manifestation, and completes in principle the revelation of the Christian idea of God, the revelation of His threefold nature and name. This revelation completed God can be thought of as absolute spirit, absolute love, absolute good, and was, to some extent explicitly, and throughout implicitly, so represented in the New Testament. It is precisely in virtue of the threefold representation of God characteristic of the New Testament that Christianity is still held by so many of the world's profoundest thinkers as the absolute and perfect religion, the crown and consummation of religion,—speculatively considered, an absolute revelation of God, and practically considered, a perfect salvation,—within which there may be infinite evolution and progress, but beyond which there can be no true light or real growth.[3]

The threefold representation of God in the New Testament was an entirely religious and practical rep-

Robertson Smith, *Prophets of Israel*, etc. As to the name "Jahveh," an instructive summary and examination of views is given by Prof. Driver in his article "Recent Theories on the Origin and Nature of the Tetragrammaton," in *Studia Biblica*, Oxford, 1885.

[3] The New Testament representation of God is treated of in the *New Testament Theologies* of Schmid, Reuss, Oosterzee, and Weiss; also in Wittichen, *Die Idee Gottes*, 1865.

Doctrine of the Trinity.

resentation, inseparably connected with the historical facts of Christ's life and the spiritual experiences of the early Christians. It was not an ontological or even theological doctrine, and will be identified by no competent exegete with the dogma of the Divine Trinity set forth in the œcumenical creeds. The propositions constitutive of the dogma of the Trinity—the propositions in the symbols of Nice, Constantinople, and Toledo relative to the immanent distinctions and relations in the Godhead—were not drawn directly from the New Testament, and could not be expressed in New Testament terms. They were the products of reason speculating on a revelation to faith—the New Testament representation of God as a father, a redeemer, and a sanctifier—with a view to conserve and vindicate, explain and comprehend it. They were only formed through centuries of effort, only elaborated by the aid of the conceptions and formulated in the terms of Greek and Roman metaphysics. The evolution of the doctrine of the Trinity was far the most important fact in the doctrinal history of the church during the first five centuries of its post-apostolic existence. To trace and describe it fully would be almost to exhibit the history of Christian thought during these centuries. It had necessarily an immense influence on the development of theism. The acceptance of the catholic doctrine of the Trinity implied the rejection of pantheism, of abstract monotheism, of all forms of monarchianism or unitarianism. It decided that theistic development was not to be on these lines or in these directions. At the same time the dogma itself was a seed for new growths of theistic thought, and demanded a development consistent with its own nature. It is a doctrine, not as to the manifestations and revelations of Godhead, but as to their ground and explanation, the constitution of Godhead, a doctrine as to a trinity of essence, which accounts for the Trinity of the gospel dispensation. It affirms the unity of God, but requires us to conceive of His unity, not as an abstract or indeterminate self-identity, not as "sterile, monotonous simplicity," but as a unity rich in distinctions and perfections,—the unity of an infinite fulness of life and love, the unity of a Godhead in which there are Father, Son, and Holy Spirit, a trinity of persons, a diversity of properties, a variety of offices, a multiplicity of operations, yet sameness of nature, equality of power and glory, oneness in purpose and affection, harmony of will and work. It finds its dogmatic expression as to what is ultimate in it in the formula—One substance in three persons, of which the first eternally generates the second, and the third eternally proceeds from the first and second. Now, manifestly, however much such a doctrine as this may have satisfied thought on a revelation as to the Godhead, it cannot have exhausted or completed it. If it answered certain questions it raised others, and these more speculative and profound than those which had been answered. What is meant by affirming God to be "substance" or "in three persons"? What is meant by divine "generation" or "procession"? How are the substance and persons related? How are the persons distinguished and interrelated? These and many kindred and connected questions reason became bound to discuss by its adoption of the doctrine of the Trinity. This obligation could only be temporarily and partially evaded or concealed by representing the doctrine as "a mystery" to be accepted simply on authority or with blind faith. Data of the doctrine may have been given to faith, but the doctrine itself was the work of reason, and on no ground not plainly absurd could that work be held to have terminated in 589 A.D. As soon as an inspired record is left at all, as soon as any speculation is allowed on its contents, as soon as the process of forming doctrine is permitted to begin, all conceivable right to stop the movement anywhere is lost. By the blending, however, of trinitarianism with theism the whole character of the latter was, of necessity, profoundly changed. A trinitarian theism must be vastly different from a unitarian as regards practice. It must be equally so as regards theory. It must be far more speculative. By its very nature it is bound to undertake speculative labors in which a simply unitarian theism will feel no call to engage.[1]

Theism in patristic writers.

It was the general conviction of the early Christian writers that formal proofs of the Divine existence were neither necessary nor useful. In their view the idea of God was native to the soul, the knowledge of God intuitive, the mind of man a mirror in which, if not rusted by sin, God could not fail to be reflected. The design argument, however, came early into use and was frequently employed. More speculative modes of reasoning were resorted to by Dionysius of Tarsus, Augustine, and Boetius. The unity of God had to be incessantly affirmed against polytheists, Gnostics, and Manichæans. The incomprehensibility of God and His cognoscibility were both maintained, although each was sometimes so emphasized as to seem to obscure the other. That the knowledge of God may be reached by the three ways of *causality*, *negation*, and *eminence* was implied by the pseudo-Dionysius, although only explicitly announced by Scotus. Neither any systematic treatment of the Divine attributes nor any elaborate discussion of single attributes was attempted. The hypothesis of eternal creation found a vigorous defender in Origen, but met with the same fate as the dualist hypothesis of uncreated matter and the pantheistic hypothesis of emanation. Of all the patristic theologians Augustine was undoubtedly the most philosophical apologist and exponent of theism. He alone attempted to refute agnosticism, and to find a basis for the knowledge of God in a doctrine of cognition in general. On the large, difficult, and as yet far from adequately investigated subject, the influence of Platonic and Aristotelian, Stoic and Academic, Neopythagorean and Neoplatonic speculation on the formation of the Christian *doctrina de Deo*, it is, of course, impossible here to enter.[2]

Mohammedanism.

Mohammed (570–632) founded a monotheistic religion which spread with amazing rapidity through Arabia, Syria, Persia, North Africa, and Spain, and gave, almost wherever it spread, a mighty impulse to the minds and wills of men. It was received as the gift of special inspiration and revelation, although its creed contained little of moment on which reason would seem to be incompetent to decide. It had obvious merits, and must be admitted to have rendered real and important services to culture, religion, and humanity, but had also conspicuous faults, which have done much injury to individual, domestic, and national life. If the latest were always the best, it would be the most perfect of the three great theistic religions of the world; but it is, in fact, the least developed and most defective. Instead of evolving and extending, it marred and mutilated the theistic idea which it borrowed. Instead of representing God as possessed of all spiritual fulness and perfections, it exhibited Him as devoid of the divinest spiritual attributes. It recognized His transcendent exaltation above His creatures, but not His sympathetic presence with His creatures; apprehended vividly His almighty power, His eternity, His omnipresence and omniscience, but only vaguely and dimly His moral glory, His love and goodness, His righteousness and holiness. The Allah of Mohammed was essentially despotic will, and so fell far below the Jahveh of Moses, essentially righteousness, and the Heavenly Father of Christ, essentially holy love. Mohammedanism is almost as contrary to Christianity as one form of theism can be to another. It is as unitarian as Christianity is trinitarian. Its cardinal tenet is as distinctly anti-trinitarian as anti-polytheistic. It has often been represented as having had the providential task assigned it of preparing the way for Christianity by destroying polytheism; in reality, it has hitherto offered a far more stubborn resistance to Christianity than any polytheistic religion has done.[1]

Mediæval theology.

The mediæval world was so complex, so full of contrasts and contradictions, that it cannot be "summed up in a formula." Most general statements current regarding it will be found on examination only partially true. It is often described as the age in which external religious authority ruled, and all religious thought ran in narrow, strictly prescribed paths, whereas, in fact, the mediæval theologians were far freer to speculate on almost all points of religious doctrine than Protestant divines have been. Because traditionalism abounded, it is forgotten that rationalism also abounded; because scholasticism flourished, that mysticism was prevalent; because theism was common, that pantheism, speculative and practical, was not uncommon. The Middle Age was, however, *par excellence*, the age of theology. Theology never before or since so interested and dominated the human intellect. Nearly every eminent mediæval thinker was a theologian. The chief streams of theistic belief and speculation which traversed the Middle Age were three,—the Christian, Jewish, and Mohammedan. The first was much the broadest and fullest. Few points of theistic doctrine were left unhandled by the Christian divines of the Middle Age. The conclusions came to on the chief points were various and divergent. As to the manner in which God is known, for instance, some laid stress on faith or authoritative revelation; others on immediate consciousness, the direct vision of the pure in heart, the illumination of the Spirit of God in the minds and hearts of the true children of God; others on reason and proof; and some attempted mediation and synthesis. Anselm gave logical form to an *a priori* argument for the Divine existence based on the idea of God as a being than whom a greater cannot be conceived. His most ingenious attempt to demonstrate the absurdity of supposing the perfect, the infinite, to be a mere subjective fiction prepared the way for the multitude of attempts, identical or similar in aim, which have since been made. Thomas Aquinas was the best representative of those who held that the invisible God was only to be known through His visible works. He argued from motion to a mover, from effect to cause, from the contingent to the necessary, from lower kinds of good to a supreme good, and from order and purpose in the world to a governing intelligence. Raymond of Sebonde added to the ontological and physico-teleological arguments a moral argument. William of Occam criticised keenly and unfavorably both the *a priori* and *a posteriori* proofs, and held that the existence of God was not a known truth but merely an article of faith. There was not less diversity of view as to how far God may be known. Erigena held that even God Himself could not comprehend His own nature, and Eckhart that the nature of God is necessarily unknowable, as being a nature without nature, without predicates, without opposites, pure oneness. That man cannot know God's real nature, cannot know Him *per essentiam*, cannot have a *quidditiva cognitio Dei*, and that the so-called attributes of God are only descriptive of the effects of His operations as they appear to the human mind, or even are merely symbols or metaphors, was maintained by many of the scholastic doctors. Aquinas, for example, with all his confidence as a dogmatic system-builder, so denied the cognoscibility of God. That the human mind may have a true, although it cannot have a perfect knowledge of God,—an apprehensive but not a comprehensive knowledge of Him,—was, however, in the Middle Age, as it has been ever since, the position most commonly taken up. The scholastic divines discussed a multitude of foolish questions regarding God, but that was not due to extravagant faith in the power of the human mind to know or comprehend God. Prof. Sheldon very justly says, "on the whole, the scholastic theology, notwithstanding some strong negative statements, assumes in reality a minimum of acquaintanceship with the essential nature of God." The negative statements are, for the most part, those of the mystics with respect to the beatific vision. Mediæval discussions as to the nature of God turned chiefly on two points,—the relation of the Divine essence to the Divine attributes and of the one Divine substance to the three Divine persons. The conclusion come to by the vast majority of scholastic theologians on the first point was that the attributes were not really or objectively in God, but merely human representations reflected, as it were, on the idea of God, because the mental constitution of man is what it is, and because God wished to be thought of in certain divers manners. To hold them objectively real in God, and therefore intrinsically distinct either from the essence of God or from one another, was considered to be incompatible both with the incomprehensibility and with the absolute simplicity of the Divine nature. Duns Scotus, in maintaining that the attributes were *formalitates realiter distinctæ*, took up an exceptional position. On the other point the conclusion as generally reached was one seemingly quite inconsistent with the foregoing, namely, that the persons were objectively and eternally real and distinct. The discrepancy is especially apparent in those theologians (*e.g.*, Anselm, Abelard, Hugo and Richard of St. Victor, Alexander of Hales, and Aquinas) who represented the persons of the Trinity as corresponding to distinctions among the very attributes which they in another reference denied to be distinct. The mediæval schoolmen, with very few and doubtful exceptions, conjoined with their theism the doctrine of the Trinity as defined by the ancient church. Roscelin of Compiègne and Gilbert de la Porrée laid themselves open to the charge of tritheism; and obviously nominalism, by allowing nothing but a nominal existence to the essence or general nature of which the individual is a specimen, tended towards tritheism,—towards resolving the Trinity into a triad of Divine individuals or self-subsistent beings, connected only by a common specific character. While the schoolmen accepted the doctrine of the Trinity on authority, they did not conceive themselves precluded from endeavoring to illustrate it and to make it appear as consonant to reason as possible. They sought to show its consistency with the unity of God, and its general reasonableness by various speculative considerations, but especially by the aid of analogies drawn from the constitution of the mind and even from particular physical phenomena. They did not suppose that they were thereby demonstrating the doctrine of the Trinity: they fully recognized that doctrine to be the indication of a mystery, "dark with excess of light," and the truth of which could only be directly apprehended in the beatific vision conferred by the highest and most special grace; but they proceeded on the belief that, inasmuch as it was a central truth of revelation, the whole creation, and above all, the nature and essence of man's spirit, must bear witness to it. At least one good result followed. Those who exercised their minds on the doctrine of the Trinity were necessarily led in some measure to form another idea of God than that of either an indeterminate unity or a confused synthesis of attributes,—to think of Him, with some clearness and steadiness, in an organic and harmonious manner, as absolute being, absolute life, absolute spirit, absolute intelligence, absolute love. Such thought as this distinctly appeared in Anselm, the St. Victors, Aquinas, Bonaventura, Dante, etc. The omnipresence, omnipotence, and omniscience of God, and, generally, what are called His metaphysical and intellectual attributes, were discussed with excessive elaborateness and subtlety, while His moral attributes were left in the background, or considered without sufficient earnestness or insight. The problems regarding the relationship of the Divine attributes to human agency, and, in particular, as to the compatibility of Divine prescience and predestination with human freedom and responsibility, were even too laboriously and minutely debated between the mediæval Augustinians and their opponents. What the disputants on both sides lacked was intellectual humility. They strode along "dim and perilous ways" as if they were in plain and safe paths, or as if their own faculties were superhuman. As to the general relation of God to the universe, few, if any, of the schoolmen can be charged with deism. While assigning to God a being and life transcending the universe, they also affirmed that He was everywhere in the universe, everywhere wholly present, everywhere essentially and actively present. Pantheism was prevalent all through the Middle Ages, but only two of its representatives, perhaps—Erigena and Eckhart,—showed much speculative capacity.[1]

---

[1] See MOHAMMEDANISM, and authorities there mentioned: also Kuenen, *Hibbert Lectures*, lect. 1, with authors and works there indicated.

Mohammedan theism.

Mohammedan theism drew chiefly from faith and fanaticism the force which carried it onwards with such rapidity in its early career of conquest. At the same time it powerfully stimulated reason, as soon appeared in remarkable intellectual achievements. Of course, reason could not fail to reflect on the contents of the faith by which it had been awakened. The result was the formation of many schools of religious opinion. So far as our subject is concerned, however, all mediæval Mohammedan thinkers may be ranked as philosophers, theologians, or mystics. The philosophers derived little of their doctrine from Mohammed. Even in what they taught regarding God they followed mainly Aristotle, and in some measure the Neoplatonists. They maintained the unity of God, but conceived of it in a way unknown to Mohammed, namely, as a unity allowing of the reality of no distinctions, qualities, or attributes in God. Then, although they affirmed the unity of God in the strictest abstract manner, they were not monists but dualists, inasmuch as they denied creation *ex nihilo*, and asserted the eternity of matter. The mode in which they supposed the multiplicity of finite things to have been produced from God was by a series of emanations originating in Divine intelligence, not in Divine will. Their proofs of the Divine existence were, for the most part, founded on the principle of causality. The philosophers did not openly oppose the theism of the Koran, but they ignored it or set it aside, and represented it as only a useful popular faith, not a response to the demands of cultured reason. The "theologians," on the other hand, took their stand upon the Koran, sought to defend and develop into doctrine its representations of God, and to show the inconclusiveness and inconsistencies of the teaching of the philosophers regarding God. Even those of them, however, who exalted faith and revelation most—the orthodox Motakallemin or Asharites—by no means dispensed with philosophy and reason. It was chiefly on the metaphysical hypothesis of the atomic constitution of matter that they rested their proofs of the Divine existence. It was by subtle reasonings that they sought to establish the non-eternity of matter and the unity and immateriality of God. It was on speculative grounds that they contended God had eternally possessed all the attributes ascribed to Him in the Koran. Their predestinationism was as logically elaborated as that of the Augustinian scholastics. There flourished for a short period a school of liberal Mohammedan theologians, the Motazilites, who, while accepting the two fundamental doctrines of Islam—the unity of God and the divine mission of Mohammed,—refused to regard the Koran as an absolute religious authority, and sought to transform Mohammedanism into a reasonable and ethical monotheism. They insisted on the rightful conformity of faith to reason, on human freedom, and on the righteousness as well as the unity of God. They endeavored, in fact, to substitute for a God whose essence was absolute or arbitrary will a God whose essence was justice. This meant, however, not to develop or even reform, but to subvert and displace the Mohammedan idea of God, and the wonder is, not that they failed in so arduous a task, but that they had the courage to undertake it. Mohammedan mysticism (Sufism) was a reaction, chiefly of the Persian mind, against the narrowness and harshness of the monotheism of the Arabian prophet. Unlike philosophy, it was not a mere exotic, but an indigenous growth within the Mohammedan area, and hence orthodoxy has never been able to eradicate it. It has been the chief support of spiritual feeling and the chief source of poetry in Mohammedan lands. It still flourishes, has branches innumerable, and through its poets has shed seed widely even over Christendom. The mystics refuse to think of God as an arbitrary unlimited Will, separate and apart from everything; as one who reveals Himself clearly only through the words of a prophet; as a being before whom man is mere dust and ashes, and who demands no higher service than fear, unquestioning faith, and outward obedience. In their view God is immanent in all things, expresses Himself through all things, and is the essence of every human soul. There is not only no God but God, but no being, life, or spirit except the being, life, and spirit of God; and every man may be God's prophet, and more even than His prophet. For a man to know God is to see that God is immanent in himself, and that he is one with God, the universal life which breathes through all things. Such knowledge or vision must glorify all nature, and must dilate and rejoice the heart of him who possesses it. Joy and ecstacy must characterize the worship of the Sufi. A religious skepticism based on philosophical skepticism—disbelief in the existence of God grounded on disbelief in any truth not guaranteed by sense or mathematical demonstration—was not unknown among the Saracens, although no work in defence of it has come down to us, and perhaps none may have been written. In Algazel philosophical skepticism was combined with religious dogmatism and mysticism. He subjected the doctrines of the philosophers to a keen and hostile criticism, and maintained that reason was incompetent to reach the knowledge of God, yet cherished an ardent and exalted faith in God, based partly on the Koran and partly on mystic contemplation and devout experience.[2]

---

[1] For the history of mediæval theism may be consulted the histories of philosophy by Tennemann, Ritter, Erdman, etc.; the special histories of mediæval philosophy by Stöckl and Haureau, and of later scholasticism by K. Werner; the histories of the Trinity and of Christian doctrine already mentioned; and a multitude of monographs, *e.g.*, those of Christlieb, Huber, and Stöckl on Erigena; of Hasse, Remusat, Bouchitté on Anselm or his ontological argument; Delitzsch's *Kritische Darstellung der Gotteslehre des Thomas Aquinas;* Ritschl's "Gesch. Studien z. ch. Lehre von Gott," in *Jahresb. f. deutsche Theol.*, x., referring chiefly to Aquinas and Scotus, etc. Mediæval mysticism has found in Schmidt, Lasson, Preger, Jundt, admirable historians. On Eckhart there are good works by Martensen, Lasson, and others; see also a paper by Prof. Pearson in *Mind*, No xli. On mediæval predestinarianism consult chapter in Mozley's *Treatise on the Augustinian Doctrine of Predestination.* The keenest hostile criticism of mediæval theism is that of Pasquale D'Ercole, *Il Teismo Filosofico Christiano*, 1884.

Theism of later Judaism.

Jewish and Mohammedan religious thought were intimately connected in the Middle Age, and ran a nearly parallel course. The Rabbanites and the Karaites of Judaism corresponded to the orthodox and the Motazilites of Mohammedanism. In their theism there was no new feature or peculiar significance. Jewish theosophic mysticism found expression in the Kabbalah. The idea of God there presented was at once excessively abstract and excessively fanciful. It must be studied, however, in the original source or in special works. The Jewish philosophers differed little from the Arabian philosophers in their teaching regarding the evidences of the Divine existence, the nature and consequences of the Divine unity, and the meaning of the Divine attributes. At the same time, they, with a few exceptions, affirmed the non-eternity of matter, and did not, like the Arabian Aristotelians, represent providence as merely general. They maintained strongly the transcendence of God and the impossibility of the human mind forming any positive conception of His essential being. They held that He was known as necessarily existent, but also as in Himself necessarily unknowable. Their view of the unity of God led them to an idea of God which may not unjustly be designated agnostic, and which prevented their regarding either nature or Scripture as a revelation of what God really is. Almost alone among eminent Jewish writers of the Middle Age, Jehuda Halevi contended that the representation of God given in the revelation to Israel was self-evidencing, independent of the support of philosophy, and unattainable in any speculative way. The function of reason was, in his view, not to sit in judgment on what had been delivered regarding God to the Jews, but to repel the objections which philosophy had brought against it, and to show the inadequacy of the results reached by unaided human intelligence. Maimonides undertook to establish that reason and faith, science and revelation, were at one in what they affirmed regarding God, but in order to make out his thesis he sacrificed the literal sense of Scripture whenever it did not accord with the tenets of his philosophy, and substituted for the representation of God given through Moses and the prophets one very different in character. His idea of God is highly abstract and metaphysical,—the idea of a being so unlike every other being that no name or predicate whatever when applied to Him can bear its ordinary, or indeed any intelligible meaning. Existence, eternity, unity, power, wisdom, justice, and other attributes, are not in Him what they are in any other being or even analogous in Him to what they are in any other being.[1]

Renaissance period.

In Christian Europe the human mind took a fresh start at the epoch of the Renaissance. It revolted against the authorities to which it had long been submissive, and exercised private judgment with a confidence uncorrected and unmoderated by experience. It turned with ardor to the free discussion of the greatest theme of thought, and probably at no period of history has there been more individual diversity of opinion on that theme. God and His relation to the universe were treated of from a multitude of points of view. Skepticism, naturalism, and pantheism appeared in various forms; all ancient systems of thought as to the Supreme Being found advocates; all modern theories as to the nature of the Divine were in some measure anticipated. Did our limits permit it would not be uninteresting to expound the speculations concerning Deity of several of the writers of the Renaissance,—and especially, perhaps, of these three—Nicolaus of Cusa, Giordano Bruno, and Thomas Campanella. The theosophic mysticism of the period was a preparation for the Reformation.[2]

The fusion of theology and philosophy was the distinctive feature of mediæval Christendom; their separation has been a marked characteristic of modern Christendom. Even when both have been occupied with religious inquiries and thoughts of God they have kept apart; they have often co-operated, but seldom commingled. Theology has been on the whole cleric, and comparatively conservative; philosophy has been on the whole laic, and comparatively progressive. But for theology holding fast to what had been handed down as truth regarding God there must have been little continuity or consistency in the development of religious convictions; but for philosophy restlessly seeking ever more light there would have been little growth or increase of knowledge of the Divine.

The Reformation.

The Reformers held that there was a knowledge of God naturally planted in the human mind, and also derivable from observation of the constitution and government of the world, but that this knowledge was so marred and corrupted by ignorance and sin as to require to be confirmed and supplemented by the far clearer and fuller light of the special revelation in the Scriptures. They were deeply sensible of the evils which had risen from the over-speculation of the scholastic divines on the nature of God, and were under the impression that it would have been well if men had been content to accept the statements of Scripture on the subject with simple and unhesitating faith. Luther wished theology to begin at once with Jesus Christ. Melanchthon said, "There is no reason why we should devote ourselves much to these most lofty subjects, the doctrine of God, of the unity of God, of the Trinity of God;" and in the early editions of his *Loci Communes* he entered into no discussion of these themes. Zwingli in his *De Vera et Falsa Religione* and even Calvin in his *Institutio Religionis Christianæ* delineated the *doctrina de Deo* only in outline and general features. In the confessions of the churches of the Reformation nothing which the ancient church had œcumenically determined as regards that doctrine was rejected, and nothing new was added thereto. It soon became apparent, however, that the mind would by no means confine its thoughts of God within the limits which the Reformers believed to be alone legitimate and safe. The idea of God is so central in religion that it must affect and be affected by every change of thought on any religious theme. The many and violent controversies within Protestantism all reacted on the doctrine relative to Deity, causing it to be studied with intense energy, but in a manner and spirit very unfavorable, on the whole, to truth and piety. Every new dispute elicited more abstruse conclusions and more subtle definitions. In the disputations of orthodox divines of the 17th and 18th centuries as to the nature, the attributes, the decrees, and the operations of God, we see scholasticism with all its peculiarities reintroduced and often exaggerated. Yet Protestant theism was in various respects an advance on that of the doctors of mediæval scholasticism. The protest of the Reformers against the faults of the scholastic treatment regarding God did not lose its pertinency or value because their own followers fell into these very faults. If the subsequent history plainly showed that the doctrine could not have been so fixedly and exhaustively determined by the ancient church as the Reformers supposed, it also showed that the scholastic treatment of the doctrine had been justly condemned by them, and that speculation regarding God when not rooted in

spiritual experience must necessarily be unfruitful. The scholasticism of Protestantism was in essential contradiction to the genius and aim of Protestantism. Then, in the Protestant doctrine of God more prominence was given than had previously been done to His manifestation in redemption, to the relation of His character towards sin, and in particular, to the attribute of justice. The strong emphasis laid on the righteousness of God marked a distinct ethical advance. At the same time the idea of God in the older Protestant theology was far from ethically complete. His fatherhood was strangely ignored or most defectively apprehended. Absolute sovereignty had assigned to it the place which should have been given to holy love, and was often conceived of in an unethical manner. Further, whereas among mediæval theologians it was the rule and not the exception, among Protestant divines it was the rare exception and not the rule, to affirm God to be unknowable. They asserted merely His incomprehensibility and man's limited knowledge of His perfections. They did not in general, however, abandon, at least explicitly, the premiss from which mediæval theologians inferred the Divine incognoscibility, namely, that the absolute simplicity of the Divine essence was incompatible with the existence of distinctions therein.[1]

Antitrinitarianism.

Deism.

Difference of opinion as to the relation of reason to Scripture was in the Protestant world one of the chief causes of difference of belief as to God. Assaults on trinitarianism were contemporary with the Reformation, and they proceeded more on the conviction that the doctrine of the Trinity was unreasonable than that it was unscriptural. The founder of Socinianism, indeed, not only fully accepted the authority of Scripture, but went so far as to represent it as the source of all religious truth, even of the primary truths of natural religion; yet, while he thus apparently and in theory attributed the knowledge of God more to Scripture and less to reason than did Luther or Calvin, really and in practice he did just the reverse, because he conceived quite otherwise of the connection between Scripture and reason. While he held Scripture to be the source of religious truth, he also held reason to be so the organ of religious truth that nothing contrary to reason could be accepted on the authority of Scripture, and that only those declarations of Scripture could be deemed to be interpreted aright which were interpreted in accordance with the axioms of reason. Luther, on the other hand, proclaimed aloud, Strangle reason like a dangerous beast if it dare to question Scripture; and Calvin, although he did not speak so harshly, demanded the unqualified submission of reason to the authority of Scripture. Antitrinitarianism has maintained its ground throughout the Protestant area, has assumed a variety of forms, and has exerted a powerful influence. It has been unable, it is often said, to do more than revive the doctrines which distracted the ancient church and were condemned by it as heresies. And this must be so far admitted. The doctrine of the Trinity comprehends only a few propositions, and every departure from it must involve a rejection of one or more of these, and must, consequently, belong to some one of a very few possible types or classes of belief. But essentially the statement is superficial and unjust. For the ways in which, and the grounds on which, both the affirmations of which the doctrine consists and the negations of these have been maintained have not been the same. Alike the defences and the attacks have in the later era implied a deeper consciousness of the nature of the problems in dispute than those of earlier times. As of history in general, so of the history of the doctrine of God, it holds good that no present has been the mere reproduction of any past. The rationalistic process was carried farther in English deism and its continental developments. Deism sought to found religion on reason alone. It represents "nature" as the sole and sufficient revelation of God. There is no warrant for the view that the deists held nature to be independent of God, self-conservative and self-operative,—or, in other words, God to be withdrawn from nature, merely looking on and "seeing it go." They believed that God acted through natural laws, and that it was doubtful if He ever acted otherwise than through these. Whatever was taught about God in Christianity and other positive religions beyond what reason could infer from nature ought, in their opinion, to be rejected as fiction and superstition. All their zeal was negative,—against "superstition." What was positive in their own doctrine had but a feeble hold on them. God was little more to them than a logical inference from the general constitution of the world. They lacked perception of the presence of God, not only in the Bible, but in all human life and history.[2]

Modern philosophy.

Modern philosophy, from its rise to the close of the 18th century, showed a double development, the one ideal and the other empirical, the Cartesian and the Baconian. The former was the more essentially religious. Descartes endeavored to found philosophy on an indubitable refutation of absolute skepticism. Such a refutation he believed himself to have effected when he had argued that thought, even in the form of doubt, necessarily implies the existence of him who thinks; that the implication yields a universal criterion of certainty; and that the presence of the idea of God in a man's mind, the consciousness of the mind's imperfections, and especially the character of the mind's concept of God as that of the most real being containing every perfection, demonstratively establish that God is and is what He is thought to be. God is and is true; therefore man has not been made to err, and whatever he clearly and distinctly sees as true must be true. In the opinion of Descartes, the idea of God is inherent in reason, is the seal of all certainty, and the corner-stone of all true philosophy. To the whole Cartesian school theology was the foundation of all science. To Spinoza, who most fully developed some of the distinctive principles of Descartes, it was identical with all science, for to him God was the only substance, and all things else were only his attributes or modes. Besides the pantheism of Spinoza, the occasionalism of Guelinx, Malebranche's vision of things in God, Leibnitz's pre-established harmony and optimism, and Wolf's rationalism were natural, if not necessary, outgrowths from the same root,—Cartesian theism. Perhaps, of all the many services to the cause of theism with which Cartesianism must be credited the greatest was that it constantly gave prominence to the absolute perfection of God.[3] Baconian or empirical philosophy was content if by the ways of causality and design, it could rise to an apprehension of a First Cause and Supreme Intelligence. It tended of itself to a phenomenalism, sensationism, associationism, unfavorable to theism.

[2] Besides the works of Gass, Frank, and Dorner already mentioned, see the histories of deism by Leland, Lechler, and Sayous; of rationalism by Stäudlin, Tholuck, Hagenbach, and Hurst; Noack's *Freidenker*, 3 vols., 1853-55; Farrar's *Crit. Hist. of Free Thought*, 1863; Hunt's *Rel. Thought in England*, 3 vols., 1870-73; Leslie Stephen's *Engl. Thought in the Eighteenth Cent.*, 2 vols., 1883; Cairn's *Unbelief in the Eighteenth Cent.*, 1881; Beard's *Hib. Lect.*, 1883, and the 2d vol. of Gillett's *God in Human Thought*, 1874.

[3] Saisset, in the first part of his *Modern Pantheism* has somewhat elaborate studies on (1) the theism of Descartes, (2) God in the system of Malebranche, (3) the pantheism of Spinoza, and (4) the theism of Leibnitz. Huber (1854) and Elvenich (1865) have written special treatises on the Cartesian proofs of the divine existence. Among the most thorough studies of Spinoza are those of Camerar, Pollock, and Martineau. Herder, Voigtländer, and others have maintained that he was a theist, not a pantheist. On the *Théodicée* of Leibnitz there are three excellent papers by Prof. Torrey in the *Andover Rev.* for October, November, and December, 1885. The best general history of philosophy is Kuno Fischer's; the best history of Cartesianism F. Bouillier's.

It was, however, counteracted, restrained, and modified by Cartesianism and Platonism, and is naturally allied itself with positive science. The massive defence of theism erected by the Cambridge school of philosophy against atheism, fatalism, and the denial of moral distinctions was avowedly built on a Platonic foundation. The popularity during the 18th century of the design argument, and what was called physico-theology, was largely due to the impression made on the general mind by the brilliant discoveries of the founders of modern astronomy, chemistry, and other physical sciences. Bishop Berkeley showed how an empirical philosophy might be logically evolved into a theistic immaterialism, Hume how it might be logically dissolved into an agnostic nihilism.

Mysticism.

In the 16th, 17th, and 18th centuries mysticism had many representatives, several of whom, as, *e.g.*, Weigel, Ottingen, Swedenborg, and especially Jacob Boehme, are entitled to a considerable place in any detailed history of theism. To the eyes of Boehme God revealed himself from without and within in the most real and intimate manner. In the powers, antagonisms, and conjunctions of creation he saw the energies, struggles, and victories of the creative Spirit itself; in the constitution and operations of physical and human nature, the essential constitution and necessary processes of the Divine nature. His thoughts of God were in striking contrast to those of the deists and natural theologians of the 17th and 18th centuries, and strikingly anticipated those of a Schelling, Hegel, and Baader in the 19th century. Could Swedenborg's doctrine of correspondences be verified, our means of insight into the character of God would be largely extended.

Nineteenth century.

The 19th century is sufficiently far advanced to allow us to see that a new epoch even in the history of theism began near its commencement. The revolution in philosophy initiated by Kant has profoundly affected theistic thought. It has introduced that type of agnosticism which is what is most original and distinctive in the antitheism of the present age, and at the same time stimulated reason to undertake bolder inquiries as to the Divine than those which Kant prohibited. The enlarged and deepened views of the universe attained through the discoveries of recent physical science have rendered incredible the idea of a God remote from the world, irresistible the conviction that the eternal source of things must be immanent in their constitution, changes, and laws. The rapid growth of biology and the spread of the doctrine of evolution have not only tended in the same direction, but given a new and nobler conception of the teleology of the universe, and, consequently, of God as the supreme intelligence. History—which the natural theologians of the 18th century so strangely ignored, which the solitary Italian thinker Vico alone recognized with clearness and comprehensiveness of vision to be necessarily the chief scene of the self-revelation of God—began with Lessing and Herder, to be generally seen in its true religious light. The comparative or historical method of study has created two disciplines or sciences, comparative theology and Biblical theology,—which are both largely occupied with tracing the development of the idea of God. The ethical spirit of the age has so told on its religious teaching that to no generation save that to which the gospel was originally given has the Divine fatherhood been so distinctly set forth as to the present. Dogmatic theology, especially in Germany, has been earnestly active; and its chief representatives have labored so to amend and advance the doctrine concerning God that it may satisfy the new requirements which have arisen.

Present state of thought.

It is now necessary briefly to indicate the present state of thought on the chief points and problems of theism.

Origin of idea of God.

As to the origin, then, of our actual idea of God, that, it is seen, can only be the whole religious history of man which precedes it, and the whole religious nature of man which underlies that history. It is absurd to refer exclusively to any faculty, intuition, or feeling, any revelation or instruction, any person or event, what can be traced in growth and formation through thousands of years, and can be shown by facts and documents to have been influenced by all the chief causes which have made history what it is. The history of the idea of God is the centre of all history, both explained by and explaining it; and our nineteenth-century idea of God is the result of the entire historico-psychological process which has produced the culture and religion of the 19th century. The idea of God is what it now is because God's whole guidance of man and man's whole search for God, the whole economy and evolution of things and the whole constitution and development of thought and feeling, have been what they have been from the beginning of history to the present time. Anthropology, comparative psychology, the science of language, comparative theology, Biblical theology, the history of philosophy, and the history of Christian doctrine, have all been engaged in attempting to discover the factors and stages of the vast and complex process which has resulted in the accepted idea of God; and by their separate and conjunct endeavors, they have succeeded in casting great light on all parts of the process.

As to the absolute historical origin of theism—as to where, when, and how the theistic conception of the Divine first obtained recognition among men—a definitive answer has not yet been reached. But the labor expended on the problem has not been wasted. It has made clearer the nature of the inquiry, rendered apparent the unsatisfactoriness of previous solutions, opened up glimpses of divers ways by which men have been led to belief in the unity of God, and accumulated means and materials for future and probably more successful work.

The question as to the psychological origin of theism cannot be wholly separated from that as to its historical origin. Unless theism can be shown to be the primitive form of religion, it cannot be held to have had an entirely peculiar and distinct psychological origin, but must be viewed as simply a phase or development of religion. It cannot be said that there is as yet agreement as to the psychological origin, or as to the psychological constitution even, of religion. The hypothesis of a simple impartation of the knowledge of God and spiritual things through primitive revelation, or through instruction and tradition which go back to the first appearance of man on earth, still retains a hold on certain conservative minds, but has received no confirmation from modern science and discovery, and is plainly of its very nature inadequate. A revelation relative to God in words or signs could have no meaning to a mind devoid of thoughts of God; spiritual instruction is only possible where there are spiritual powers to understand and profit by it; tradition will carry nothing far to which intelligence is indifferent. There have been many attempts made during the present century to refer the origin of belief in God to some emotional source, some element or state of sensitivity. Thus Strauss has reaffirmed the hypothesis of Epicurus, Lucretius, and Hume, that fear made the gods; Feuerbach has resolved religion into desire, God being conceived to be what man would wish himself to be; Schleiermacher has argued that a feeling of absolute dependence, of pure and complete passiveness, is our evidence for the presence of an infinite energy, and infinite being; Mansel has represented the feeling of dependence and the conviction of moral obligation as the sources of the religious consciousness; Pfleiderer represents religion as a response to the sense of conflict and contradiction between man's feelings of dependence and of freedom; Rauwenhoff traces its origin to respect (*Achtung*), the root also of moral conduct and of family life; others have referred it to specific ethical feelings; and many have represented it to be essentially love. The number of these attempts and the diversity of these results are explained by the complexity of religious feeling. In religion all the feelings which raise man above the merely animal condition are involved. Man is not religious by any one feeling or by a few feelings, but by the whole constitution of his emotional nature. His heart, with all its wealth of feelings, has been made for God. Hence, all the theories referred to have easily been shown to be one-sided, and to have exaggerated the significance and influence in religion of particular emotional elements, but hence also they all contain more or less important portions of the truth, and have all contributed towards a knowledge of the full truth. Man is not only, however, disposed by all his chief sentiments for religion, but all these sentiments, when normally and healthfully developed, tend towards theism. It is only in a theistic form of religion that they can find true rest and satisfaction. One God can alone be the object of the highest devotional fear, can alone be regarded as ideally perfect, or as a being on whom the worshipper is absolutely dependent, can alone be loved with the whole heart and esteemed with undivided reverence, can alone be recognized as the sole author of the moral law, the alone good. The theories which trace the origin of religion to feeling have the merit of recognizing that religion is not an affair of mere intellect; that the Divine could not even be known by men if they had not feelings and affections as well as intellectual powers; that, if God be love, for example, He can only be known by love; that, if He have moral attributes, we must have moral feelings in order to be able to recognize them. On the other hand, in so far as those theories represent religion as reducible to mere feeling or as independent of intellect, they have the fault of overlooking that all the feelings included in religion presuppose apprehensions and judgments, and are valid only in so far as they have the warrant of intelligence. It is as much an error, however, to account for religion by any one intellectual principle as by any one emotional element. Religion has no one special seat, such as "the central point of unity behind consciousness," imagined by Schleiermacher; no "special organ," such as "conscience," was supposed to be by Schenkel; and no one special principle of cognition, such as the law of causality has been represented to be by several philosophers and theologians. All the ultimate principles of cognition are involved in religion, and all lead, if consistently followed far enough, to theism. The whole head, as well as the whole heart, has been made for religion, and for the perfect form of religion. Max Müller, in his *Hibbert Lectures*, traces the idea of God to a special faculty of religion—"a subjective faculty for the apprehension of the infinite," "a mental faculty, which, independent of, nay, in spite of, sense and reason, enables man to apprehend the infinite under different names and under varying disguises." This view will not bear, perhaps, a close scrutiny. The infinite, as an *implicit condition* of thought, is not more involved in religious than in other thought. We cannot think anything as finite without implying the infinite. Space cannot be thought of except as *extensively*, nor time except as *protensively*, infinite. As a condition of thought, the infinite is involved in religious knowledge only so far as it is involved in all knowledge. On the other hand, as an *explicit object* of thought, it is not present in the lower forms of religion at all, which exist only because the thought of infinity is not associated in the religious consciousness with that of Deity, except where reflection is somewhat highly developed; and, even in the highest stages of religion, it is only apprehended as one aspect of Deity. Infinity is not God, but merely an attribute of the attributes of God, and not even an exclusively Divine attribute. The hypothesis that the idea of God is gained by intuition or vision is proved to be erroneous by the fact that the idea of God, and the process by which it is reached, are capable of being analyzed, and therefore not simple, and likewise by the variety and discordance of the ideas of God which have been actually formed. The apprehension of God seems to be only possible through a process which involves all that is essential in the human constitution—will, affection, intelligence, conscience, reason,—and the ideas which they supply—cause, design, goodness, infinity, etc. These are so connected that they may all be embraced in a single act and coalesce in one grand issue. During the last thirty years there has been more psychological investigation as to the origin and nature of religion than during all previous history, and the whole tendency of it has been to set aside all solutions which represent man as religious only in virtue of particular sentiments or principles, and to make manifest that the psychology of religion is that of the entire human nature in a special relationship The best of the later investigations are much more thorough and comprehensive than any of earlier date.[1]

Kantian agnosticism.

The agnosticism originated by Kant has been one of the distinctive and prominent phenomena in the history of religion and theism during the 19th century. It sprang out of an earlier agnosticism. Hume and his predecessors admitted that the conditions of thought—otherwise, the categories of experience or ideas of reason—were in appearance necessary and objectively valid, but in reality only arbitrary and subjective, their seeming necessity and objectivity being illusory, and consequent on mere repetitions and accidental associations of sensations and feelings. Kant showed that they were not only seemingly but really necessary to thought, and irresolvable into the particular in experience. He denied, however, that we are entitled to consider them as of more than subjective applicability,—that what we necessarily think must necessarily be, or be as we think it. He affirmed all knowledge to be confined to experience, the phenomenal, the conditioned. It was quite in accordance with this view of the limits of knowledge that he should have denied that we can know God, even while he affirmed that we cannot but think of God. It was by no means in obvious harmony with it that he should have affirmed that we must, on moral grounds, retain a certain belief in God. Sir W. Hamilton and Dean Mansel followed Kant in holding that we can have no knowledge of God in Himself, as knowledge is only of the relative and phenomenal. They strove to show that the notions of the unconditioned, the infinite, the absolute, are mere negations of thought, which destroy themselves by their mutual contradictions and by the absurdities which they involve. Yet both of these philosophers held that there is a revelation of God in Scripture and conscience, and that we are bound to believe it, not indeed as teaching us what God really is, but what He wishes us to believe concerning Him. Herbert Spencer, adopting Kant's theory of the limits of knowledge, and regarding as decisive Hamilton and Mansel's polemic against the philosophies of the Absolute, has concluded that the only truth underlying professed revelations, positive religions, and so-called theological sciences is the existence of an unknowable and unthinkable cause of all things. In the view of the Positivist the unknowable itself is a metaphysical fiction. The Kantian doctrine has had a still more extensive influence in Germany than in Britain, and German philosophers and theologians have displayed great ingenuity in their endeavors to combine with it some sort of recognition of God and of religion. Fries, De Wette, and others have relegated religion to the sphere of faith, Schleiermacher and his followers to that of feeling, Ritschl and his school to that of ethical wants, F. A. Lange to that of imagination, etc. Their common aim has been to find for piety towards God a special place which they can fence off from the rest of human nature, so as to be able to claim for religion independence of reason, speculation, and science, a right to existence even although necessarily ignorant of the object of its faith, feeling, moral sense, or phantasy.[2]

The movement indicated has led to no direct conclusion which has obtained, or is likely to obtain, general assent. It has had, however, a very important indirect result. It has shown how interested in, and dependent on, a true criticism or science of cognition are theism and theology. It has made increasingly manifest the immense significance to religion of the problem as to the powers and limits of thought which Kant stated and discussed with so much vigor and originality. Hence research into what the Germans call "die erkenntnisstheoretischen Grundsätze"—the philosophical basis—of theism has been greatly stimulated and advanced by the movement. This is an enormous gain, which more than compensates for sundry incidental losses. Kant's solution of the problem which he placed in the foreground of philosophy has not been found to be one in which the mind can rest. From his agnosticism down to the very empiricism which it was his aim to refute descent is logically inevitable. The agnosticism of piety has in no form been able to discover a halting place,—a spot on which to raise theism or any solid religious construction. In no form has it been able to prove its legitimacy, to maintain its self-consistency, or to defend itself successfully against the agnosticism of unbelief. It is, therefore, not suprising that it should have been very generally regarded as dangerous to theism in reality, even when friendly to it in intention. Yet there is much in the theory of cognition on which it proceeds which the theist can utilize. Indeed, no theory of cognition can afford a satisfactory basis to theism which does not largely adopt and assimilate that of

---

Hermann's in his *Die Religion im Verhältniss zum Welterkennen und zur Sittlichkeit*, 1879; Kaftan's in his *Das Wesen der chr. Religion*, 1881; Lipsius's in his *Philosophie und Religion*, 1885; and Rauwenhoff's in his "Ontstaan van den Godsdienst," *Theol. Tijdschr.*, May, 1885.

[2] Among works in which it is denied that the real nature of God can be known are—Kant's *Kr. d. r. V.;* Fichte's *Kr. aller Offenbarung;* Schleiermacher's *Reden*, *Dialektik*, and *Glaubenslehre;* Trendelenburg's *Log. Untersuchungen*, ii. §§ xx.-xxiv.; Hamilton's *Lect. on Met.*, and *Discussions;* Mansel's *Bampton Lect.*, and *Philosophy of the Conditioned;* H. Spencer's *First Principles;* and the writings of Lange, Ritschl, and other Neo Kantists. Among works in which the real cognoscibility of God is affirmed are—Calderwood's *Ph. of the Infinite;* C. Hodge's *Sys. Th.*, i.; M'Cosh's *Int. of the Mind*, *Phil. Series*, etc.; H. B. Smith's *Intr. to Ch. Th.*, and *Faith and Philosophy;* Maurice's *What is Revelation?* Young's *Province of Reason;* and Harris's *Phil. Bases of Theism*. See also L. Robert. *De la Certitude*, etc., 1880; Ollé-Laprune, *De la Certitude Morale*, 1880; G. Derepas. *Les Théories de l'Inconnaissable*, 1883; G. Matheson, in *Can the Old Faith Live with the New?* 1885; R. T. Smith, *Man's Knowledge of Man and of God*, 1886; Schramm, *Die Erkennbarkeit Gottes*, 1876; and Bertling, *Die Erkennbarkeit Gottes*, 1885.

Kant. He has conclusively shown that all our knowledge is a synthesis of contingent impressions and necessary conditions; that without the latter there can be neither sense, understanding, nor reason; that they constitute intelligence, and are the light of mind; that they also pervade the whole world of experience and illuminate it; that there is neither thing nor thought in the universe which does not exhibit them in some of their aspects; that apart from them there can be no reality, no truth, no science. The agnostic corollaries appended to this theory by Kant and others, instead of being necessary consequences from it, are inconsistent with it. Kant and the agnostics say that we know only the conditioned; but what they prove is that we know also the conditions of thought, and that these conditions are themselves unconditioned, otherwise they would not be necessary. They affirm that we can know only the phenomenal and relative, but what they establish is that it is as impossible to know only the relative and phenomenal as to know only the absolute and noumenal, and that in so far as we know at all we know through ideas which are absolute and noumenal in the only intelligible, and in a very real and important, sense. They maintain, what is very true, if not a truism, that the categories are only valid for experience, and they imply that this is because experience limits and defines the categories, whereas, according to their own theory, it is the categories which condition experience and enter as constituents into all experience, so that to say that the categories are only valid for experience means very little, experience merely existing so far as the categories enable us to have it, and being valid so far as the categories are legitimately applied, although not farther, which leaves no more presumption against religious experience than against sensible experience. They have denied the objective validity of the categories or necessary conditions of thought. This denial is the distinctive feature of all modern agnosticism; and the theist who would vindicate the reality of his knowledge of God, the legitimacy of his belief in God, the worth of his religious experience, must refute the reasonings by which it has been supported; show that conciousness testifies against it, the subjectivity of any true category being unthinkable and inconceivable; and indicate how its admission must subvert not only the foundation of theology but of all other sciences, and resolve them all into castles in the air, or into such stuff as dreams are made of. In the accomplishment of this task as much guidance and aid may be found, perhaps, in the theories of cognition of Ferrier and Rosmini as from those of any of the Germans; but Hegel and his followers, not a few of the Herbartists, Ulrici, Harms, and many other German thinkers, have contributed to show the falsity of the critical theory at this point. Amended here, it is a theory admirably fitted to be the corner-stone of a philosophical theism.

Philosophy of the Absolute.

More may be attempted to be done in the region of the necessary and unconditioned. The conditions of thought, the categories of experience, the ideas of reason are all linked together, so that each has its own place and is part of a whole. And of what whole? The idea of God. All the metaphysical categories are included therein, for God is the Absolute Being; all the physical categories, for He is Absolute Force and Life; all the mental categories, for He is Absolute Spirit; all the moral categories, for He is the Absolutely Good. The idea of God is the richest, the most inclusive, the most comprehensive, of all ideas. It is the idea of ideas, for it takes up all other ideas into itself and gives them unity, so that they constitute a system. The whole system issues into, and is rendered organic by, the idea of God, which, indeed, contains within itself all the ideas which are the conditions of human reason and the grounds of known existence. All sciences, and even all phases and varieties of human experience, are only developments of some of the ideas included in this supreme and all-comprehensive idea, and the developments have in no instance exhausted the ideas. Hence in the idea of God must be the whole truth of the universe as well as of the mind. These sentences are an attempt to express in the briefest intelligible form what it was the aim of the so-called philosophy of the Absolute to prove to be not only true, but *the truth*. Hegel and Schelling, Krause and Baader, and their associates, all felt themselves to have the one mission in life of making manifest that God was thus the truth, the light of all knowledge, self-revealing in all science, the sole object of all philosophy. The Absolute with which they occupied themselves so earnestly was no abstraction, no fiction, such as Hamilton and Mansel supposed it to be,—not the wholly indeterminate, not that which is out of all relation to everything or to anything, not the Unknowable,—but the ground of all relationship, the foundation alike of existence and of thought, that which it is not only not impossible to know, but which it is impossible not to know, the knowledge of it being implied in all knowledge. Hegel expressed not only his own conviction, but the central and vital thought of the whole anti-agnostic movement which culminated in him when he wrote, "The object of religion is, like that of philosophy, the eternal truth itself in its objective existence; it is God, and nothing but God, and the explanation of God. Philosophy is not a wisdom of the world, but a knowledge of the unworldly; not a knowledge of outward matter, of empirical being and life, but knowledge of that which is eternal, of that which is God and which flows from His nature, as that must manifest and develop itself. Hence philosophy in explaining religion explains itself, and in explaining itself explains religion. Philosophy and religion thus coincide in that they have one and the same object." The adherents of the philosophy of the Absolute must be admitted to have fallen, in their revulsion from agnosticism, into many extravagances of gnosticism; but a theist who does not sympathize with their main aim, and even accepts most of the results as to which they are agreed, cannot be credited with having much philosophical insight into what a thorough and consistent theism implies. A God who is not the Absolute as they understood the term, not the Unconditioned revealed in all that is conditioned, and the essential content of all knowledge at its highest, cannot be the God either of a profound philosophy or a fully-developed religion. The philosophy of the Absolute was, on the whole, a great advance towards a philosophical theism.[1]

And yet it was largely pantheistic, and tended strongly towards pantheism. This was not surprising. Any philosophy which is in thorough earnest to show that God is the ground of all existence and the condition of all knowledge must find it difficult to retain a firm grasp of the personality and transcendence of the Divine and to set them forth with due prominence. Certainly some of the most influential representatives of the philosophy of the Absolute ignored or misrepresented them. The consequence was, however, that a band of thinkers soon appeared who were animated with the most zealous desire to do justice to these aspects of the Absolute, and to make evident the one-sidedness and inadequacy of every pantheistic conception of the Divine. This was the common-aim of those who gathered around the younger Fichte, and whose literary organ was the *Zeitschrift für Philosphie*. Chalybäus, K. Ph. Fischer, Sengler, Weisse, Wirth, and Ulrici may be named as among the ablest and most active. The Roman Catholic Günther and his followers worked in much the same spirit. Lotze has effectively co-operated by his ingenious defence of the thesis that "perfect personality is to be found only in God, while in all finite spirits there exists only a weak imitation of personality; the finiteness of the finite is not a productive condition of personality, but rather a limiting barrier to its perfect development." This movement also, then, has tended to develop and contributed to enrich the theory of theism. Its special mission has been to prove that theism is wider than pantheism, and can include all the truth in pantheism, while pantheism must necessarily exclude truth in theism essential to the vitality and vigor both of religion and of morality.[2]

The philosophy of the Absolute, judged of from a distinctly theistic point of view, was defective on another side. It regarded too exclusively the necessary and formal in thought, trusted almost entirely to its insight into the significance of the categories and its powers of rational deduction. Hence the idea of the Divine which it attained, if vast and comprehensive, was also vague and abstract, shadowy and unimpressive. Correction was needed on this side also, and it came through Schleiermacher and that large company of theologians, among whom Lipsius and Ritschl are at present the most prominent, who have dwelt on the importance of proceeding from immediate personal experience, from the direct testimony of pious feeling, from the practical needs of the moral life, etc. From these theologians may be learned that God is to be known, not through mere intellectual cognition, but through spiritual experience, and that no dicta as to the Divine not verifiable in experience, not efficacious to sustain piety and to promote virtue, to elevate and purify the heart, to invigorate the will, to ennoble the character, to sanctify both individuals and communities, are likely to be true. Experience of the Divine can be the richest and surest experience only if it not merely implies all that is absolute and necessary in consciousness and existence, but is also confirmed and guaranteed by all that is relative and contingent therein.

[1] On the doctrine of God propounded by the philosophers of the Absolute may be consulted the histories of philosophy by Chalybäus, Michelet, Erdmann, Ueberweg, K. Fischer, Harms, Zeller, etc., also Pünjer, ii. bks. 3 and 5; the chapters in Pfleiderer on Schelling, Hegel, Neo-Schellingianism, and Neo-Hegelianism; Dorner's *Hist. of Prot. Th.*, ii. 257, 395; Lichtemberger's *Hist. des Idèes Religieuses en Allemagne*, etc., *passim*; Ehrenhaus's *Hegel's Gottesbegriff*, etc.; Franz on Schelling's *Positive Philosophie*; Opzoomer's *Leer van God, bij Krause*; K. Ph. Fischer's *Characteristik der Theosophie Baaders*; etc.

[2] See art. "Theismus," by Ulrici, in Herzog's *Real-Encyklopädie*, xv. As representing this phase of theism the following works may be named: C. H. Weisse's *Idee der Gottheit*, 1844 and *Philosophische Dogmatik*, 1855; Wirth's *Speculative Idee Gottes*, 1845; Sengler's *Idee Gottes*, 1845–47; J. H. Fichte's *Speculative Theologie*, 1846–47; Hanne's *Idee der absoluten Persönlichkeit*, 1867; Ulrici's *Gott u. die Natur*, 1875; and Lotze's *Microcosmos*, ii. ix. 4-5 (Eng. tr.) The school is well represented in America by Prof. Bowne. See his *Studies in Theism*, especially ch. 7–9. See also art. of Prof. J. S. Candlish on "The Personality of God," in *Princeton Rev.*, Sept., 1884, and of Gardiner on "Lotze's Theistic Philosophy," in *Presby. Rev.*, Oct., 1885.

Theistic "proofs."

What are known as "the proofs" for the Divine existence have from the time of Kant to the present been often represented as sophistical or useless. This view is, however, less prevalent than it was. During the last twenty years the proofs have been in much greater repute, and have had far more labor expended on them, than during the previous part of the century. They have, of course, been considerably modified, in conformity with the general growth of thought and knowledge. For instance, they are no longer presented elaborately analyzed into series or groups of syllogisms. It is recognized that the fetters which would assuredly arrest the progress of physical and mental science cannot be favorable to that of theology. It is recognized that the validity of the proofs must be entirely dependent on the truthfulness with which they indicate the modes in which God reveals Himself, the facts through which man apprehends the presence and attributes of God, and that, therefore, the more simply they are stated the better. Man knows God somewhat as he knows the minds of his fellow-men—namely, inferentially,—yet through an experience at once so simple and so manifold that all attempts at a syllogistic representation of the process must necessarily do it injustice. The closeness and character of the connection of the proofs have also come to be more clearly seen. They are perceived to constitute an organic whole of argument, each of which establishes its separate element, and thus contributes to the general result—confirmatory evidence *that* God is, and complementary evidence as to *what* God is. The explanation of this doubtless is that the apprehension of God is itself an organic whole, a complex and harmonious process, involving all that is essential in the human mind, yet all the constitutents of which are so connected that they may be embraced in a single act and coalesce into one grand issue.

The cosmological argument.

The cosmological argument concludes from the existence of the world as temporal and contingent, conditioned and phenomenal, to the existence of God as its one eternal, unconditioned, self-existent cause. It is an argument which has been in no respect discredited by recent research and discussion, which is in substance accepted not only by theists but by pantheists, and which forms the basis even of the philosophy of Herbert Spencer. The principle on which it proceeds—the principle of causality—has only come to be more clearly seen to be ultimate, universal, and necessary. The hypothesis of an infinite series of causes and effects has not had its burden of irrationality in the least diminished. The progress of science has not tended to show that the world itself may be reasonably regarded as eternal and self-existent; in the view of theists it has only tended to render more probable the doctrine that all physical things must have their origin in a single non-physical cause. The necessity of determining aright the bearings of the new views reached or suggested by science as to the ultimate constitution of matter, the conservation of energy, cosmic evolution, the age and duration of the present physical system, etc., has been the chief factor in the latest developments of the argument *a contingentia mundi*. The teleological argument, which concludes from the regularities and adjustments, preconformities and harmonies, in nature that its first cause must be an intelligence, has been both corrected and extended owing to recent advances of science and especially of biological science. The theory of evolution has not shaken the principle or lessened the force of the argument, while it has widened its scope and opened up vistas of grander design, but it has so changed its mode of presentation that already the *Bridgewater Treatises* and similar works are to some extent antiquated. Perhaps the most promising of the later applications of the argument is that which rests on the results obtained by a philosophical study of history, and which seeks to show that the goal of the evolution of life, so far as it has yet proceeded, is the perfecting of human nature, and the eternal source of things a power which makes for truth and righteousness. The ethical argument—the proof from conscience and the moral order—held a very subordinate place in the estimation of writers on natural theology until Kant rested on it almost the whole weight of theism. It has ever since been prominent, and has been the argument most relied on to produce practical conviction. Much importance is now rarely attached to those forms of the metaphysical argument which are deductions from a particular conception, as, *e.g.*, of a perfect being. Ignorance alone, however, can account for the assertion often met with that the argument is generally abandoned. It has only been transformed. It has passed from a stage in which it was presented in particular ontological forms into one in which it is set forth in a general epistemological form. As at present maintained it is to the effect that God is the idea of ideas, the ultimate in human thought, without whom all thought is confusion and self-contradiction. In this form, by what theologians and religious philosophers possessed of much speculative insight is it not held?[1]

The changes adopted in the methods of theistic proof have all tended in one direction, namely, to remove or correct extreme and exaggerated conceptions of the Divine transcendence and to produce a true appreciation of the Divine immanence,—to set aside deism and to enrich theism with what is good in pantheism. The general movement of religious speculation within the theistic area has been towards mediation between the extremes of pantheism and of deism, towards harmonious combination of the personal self-equality and the universal agency of the Divine. Positive science has powerfully co-operated with speculation in giving support and impulse to this movement. While the modern scientific view of the world does not result in pantheism, it affords it a partial and relative justification, and requires a theism which, while maintaining the personality of God, recognizes God to be in all things and all things to be of God, through God, and to God. It may be said that theism has always thus recognized the Divine immanence. The vague recognition of it, however, which precedes scientific insight and the conquest and absorption of pantheism is not to be identified with the realizing comprehension of it which is their result.[2]

The idea of God in contemporary theology.

As to the further treatment of the idea of God in recent or contemporary theology, the following may be mentioned as, perhaps, the chief distinctive features: first, the general endeavor to present the idea as a harmonious reflex of the Divine nature and life, instead of as a mere aggregate of attributes; secondly, and consequently, the greater care shown in the classification and correlation of the attributes, so as to refer them to their appropriate places in the one great organic thought; and, thirdly, the more truly ethical and spiritual representation given of the Divine character. To realize the nature and import of the first of these features it is only necessary to compare the expositions given of the idea of God in the works of such theologians as Nitzsch, Thomasius, Dorner, Philippi, Kahnis, and even more in those of the representatives of German speculative theism, with such as are to be found in the treatises of Hill, Watson, Wardlaw, and Hodge, which, although published in the present century, express only the views of an earlier age. As to the second point, there has of late been a vast amount of thought expended in endeavoring so to classify and co-ordinate the attributes, and so to refer them to the various moments of the Divine existence and life, as that God may be able to be apprehended both in His unity and completeness, self-identity and spiritual richness, as one whole harmonious and perfect personality. Of the work attempted in this direction our limits will not allow us to treat. In regard to the third feature, any one who will peruse an essay like Weber's *Vom Zorne Gottes*, or Ritschl's *De Ira Dei*, and compares the way in which the Biblical conception of the wrath of God is there presented with the mode of exhibiting it prevalent for so many ages, is likely to be convinced that considerable progress has been made even in recent times in the study of the moral aspects of God's character. That the Divine glory must centre in moral perfection, in holy love, is a thought which is undoubtedly being realized by all theists with ever-increasing clearness and fulness.[3]

[1] See the present writer's *Theism*, and the indications of the literature given in the notes.

[2] See the extremely interesting papers by Peabody, Montgomery, Howison, and Harris in the *Journal of Speculative Philosophy* for Oct., 1885, on the question, "Is Pantheism the Legitimate Outcome of Modern Science?" Also F. E. Abbot's *Scientific Theism*, 1885; and J. Fiske's *Idea of God as affected by Modern Knowledge*, 1885.

[3] Bruch, *Lehre von den Göttl. Eigenschaften*, 1842; Moll, *De Justo Attributorum Dei Discrimine*, 1855. Both are, however, already inadequate.

Advance of trinitarian theism.

It follows from the above that theistic thought has been moving in a direction which could not fail to suggest to those influenced by it that a rigidly unitarian conception of God must be inadequate, and that the trinitarian conception might be the only one in which reason can rest as self-consistent. So long as the simplicity of the Divine nature was conceived of as an abstract self-identity, intelligence could not venture to attempt to pass from the unity to the trinity of the Godhead, or hope for any glimpse of the possibility of harmoniously combining them. But, this view of the simplicity of the Divine nature having been abandoned, and an idea of God attained which assigns to Him all the distinctions compatible with, and demanded by, completeness and perfection of personality, the doctrine of the Trinity necessarily entered on a new stage of its history. The free movement of thought in this century, far from expelling it from its place in the mind of Christendom, has caused it to strike deeper root and grow with fresh vigor. Never since the Nicene age has theological speculation been so actively occupied with the constitution of the Godhead, and with the trinitarian representation thereof, as from the commencement of the present century. It is, of course, impossible here to describe any of the attempts which, during this period, have been made to show that the absolute Divine self-consciousness implies a trinitarian form of existence, and that intelligently to think the essential Trinity is to think those moments in the Divine existence without which personality and self-consciousness are unthinkable; or that a worthy conception of Divine love demands a trinitarian mode of life; or that a world distinct from God presupposes that God as triune is in and for Himself a perfect and infinite world, so that His attributes and activities already fully realized in the trinitarian life can proceed outwards, not of necessity but of absolute freedom; or that the whole universe is a manifestation of His triune nature, and all finite spiritual life a reflection of the archetypal life, self-sustained and self-fulfilled therein. All the more thoughtful trinitarian divines of the present endeavor to make it apparent that the doctrine of the Trinity is not one which has been merely imposed upon faith by external authority, but one which satisfies reason, gives expression to the self-evidencing substance of revelation, and explains and supports religious experience. If it be thought that their success has not been great, it has to be remembered that they have been laboring near the commencement of a movement, and so at a stage when all individual efforts can have only a very limited worth. To one general conclusion they all seem to have come, namely, that the idea of God as substance is not the only idea with which we can connect, or in which we may find implied, tri-personality. The category of substance is, in some respects, one very inapplicable to God, as the philosophy of Spinoza has indirectly shown. If the theologians referred to be correct, the doctrine of the Trinity is not specially dependent upon it. In their view God cannot be thought of consistently as, *e.g.*, Absolute Life, Absolute Intelligence, or Absolute Love, unless He be thought of in a trinitarian manner.

Position of unitarian theism.

While trinitarian theism has thus during the present century shown abundant vitality and vigor, it cannot be said to have gained any decided victory over unitarian theism. The latter has also within the same period spread more widely and shown more practical activity, more spiritual life, than in any former age. The unitarianism represented by a Martineau is a manifest advance on that which was represented by a Priestley. Theism in its unitarian form is the creed of very many of the most cultured and most religious minds of our time, alike in Europe and America. In this form it has also signally shown its power in contemporary India. Brahmoism is, perhaps, the most remarkable example of a unitarian theism which exhibits all the characteristics of a positive faith and a churchly organization. The unitarian theism of the present age is distinguished by the great variety of its kinds or types. None of these, it must be added, are very definite or stable. Hence unitarian theism is often seen to approximate to, or become absorbed into, agnosticism or pantheism, cosmism or humanitarianism. This may be due, however, less to its own character than to the character of the age.[1]

Man's interest in the idea of God.

The mind of man has clearly not yet ceased to be intensely interested in thoughts of God. There are no grounds apparent for supposing that it will ever cease to seek after Him or to strive to enlarge its knowledge of His ways. And if the idea of God be what has been suggested in the foregoing pages, the search for God cannot fail to meet with an ever-growing response. If the idea of God be the most comprehensive of ideas, inclusive of all the categories of thought and implicative of their harmonious synthesis and perfect realization, all thought and experience must of its very nature tend to lead onwards to a fuller knowledge of God. For the knowledge of God, on this view, consists in no mere inference reached through a process of theological argumentation, but in an ever-growing apprehension of an ever-advancing self-revelation of God; and all philosophy, science, experience, and history must necessarily work together to promote it.

Growth of the idea in speculative thought.

All speculative thought, whether professedly metaphysical or professedly theological, is conversant with ideas included in the idea of God. It deals with what is necessary in and to thought; and within that sphere, notwithstanding many aberrations, it has made slow but sure progress. The history of philosophical speculation is not only, like the whole history of man, essentially rational, but it is, in substance, the history of reason itself in its purest form,—not the record of an accidental succession of opinions, but of the progressive apprehension by reason of God's revelation of Himself in its own constitution. "There is much in the history of speculative thought, just as in the outward life of man, that belongs to the accidental and irrational—errors, vagaries, paradoxes, whimsicalities, assuming in all ages the name and the guise of philosophy. But, just as the student of the constitutional history of England can trace, amidst all the complexity and contingency of outward and passing events, through successive times and dynasties, underneath the waywardness of individual passion and the struggle for ascendency of classes and orders, the silent, steady development of that system of ordered freedom which we name the constitution of England, so, looking back on the course which human thought has travelled, we shall be at no loss to discern beneath the surface change of opinions, unaffected by the abnormal displays of individual folly and unreason, the traces of a continuous onward movement of mind."[2] And this continuous onward movement is towards the clearer and wider apprehension of the whole system of ultimate truths which is comprehended in the idea of the Absolute Truth. The thoughts of men as to God are necessarily enlarged by increase of insight into the conditions of their own thinking. The disquisitions of merely professional theologians on the nature and attributes of God have done far less to elucidate the idea of God than the philosophical views of great speculative thinkers, and would have done less than they have actually accomplished were it not for the guidance and suggestion found in these views.

Contributions of science;

The sciences co-operate with speculative philosophy and with one another in aiding thought to grow in the knowledge of God. The greatness, the power, the wisdom, the goodness, of the God of creation and providence must be increasingly apprehended in the measure that nature and its course, humanity and its history, are apprehended; and that measure is given us in the stage of development attained by the sciences. "God's glory in the heavens," for example, is in some degree visible to the naked eye and uninstructed intellect, but it becomes more perceptible and more impressive with every discovery of astronomy. Not otherwise is it as regards all the sciences. Each of them has its distinctive and appropriate contribution to bring towards the completion of the revelation of God, and cannot withold it.

of moral experience;

But the idea of God is not one which can be rightly apprehended merely through intellect speculatively exercised or operating on the findings of science. It requires to be also apprehended through moral experience and the discipline of life. Neither individuals nor communities can know more of God as a moral being than their moral condition and character permit them to know. The apprehension of God and the sense of moral distinctions and moral obligations condition each other and correspond to each other. History shows us that sincere and pious men may receive as a supernaturally revealed truth the declaration that God is love, and yet hold that His love is very limited, being real only to a favored class, and that He has foreordained, for His mere good pleasure, millions of the human race to eternal misery. How was such inconsistency possible? Largely because these men, notwithstanding their sincerity and piety, were lacking in that love to man through experience of which alone God's love can be truly apprehended. In like manner, it is not only the science of law which cannot advance more rapidly than the sense of justice, but also theology so far as it treats of the righteousness of God. Thus the knowledge of God is conditioned and influenced by the course of man's moral experience.

of religious experience.

The same may be said of the distinctively religious experience. In it also there has been a continuous discovery and a continuous disclosure of God. It is not long since the ethnic religions were very generally regarded as merely stages of human folly, so many monuments of aversion to God and of departure from the truth as to God. It was supposed that they were adequately described when they were called "idolatries" and "superstitions." This view rested on a strangely unworthy conception both of human nature and of Divine providence, and is fast passing away. In its place has come the conviction that the history of religion has been essentially a process of search for God on the part of man, and a process of self-revelation on the part of God to man, resulting in a continuous widening and deepening of human apprehension of the Divine. All, indeed, has not been progress in the history of religion either in the ethnic or Christian period; much has been the reverse; but all stages of religion testify that man has been seeking and finding God, and God making Himself known unto man.

Coming struggles with agnosticism.

But, while knowledge of God may reasonably be expected unceasingly to grow, in all the ways which have been indicated, from more to more, it is not to be supposed that doubt or denial of God's existence must, therefore, speedily disappear. Religious agnosticism cannot fail to remain long prevalent. The very wealth of contents in the idea of God inevitably exposes the idea to the assaults of agnosticism. All kinds of agnosticism merge into agnosticism as to God, from the very fact that all knowledge implies and may contribute to the knowledge of God. The more comprehensive an idea is from the more points can it be assailed, and the idea of God being comprehensive of all ultimate ideas, may be assailed through them all, as, for example, through the idea of being, or of infinity, or of causality, or of personality, or of rectitude. Then in another way, the unique fulness of the idea of God explains the prevalence of agnosticism in regard to it. The ideas are not precisely in God what they are in man or nature. God is being as man or nature is not; for He is independent and necessary being, and in that sense the one true Being. God is not limited by time and space as creatures are; for, whereas duration and extension merely are predicates of creatures, the corresponding attributes of God are eternity and immensity. God as first cause is a cause in a higher and more real sense than any second cause. So as to personality, intelligence, holiness, love. Just because the idea of God is thus elevated in all respects, there are many minds which fail or refuse to rise up to it, and which because of its very truth reject it as not true at all. They will not hear of that Absolute Truth which is simply the idea of God; but that they reject it is their misfortune, not any argument against the truth itself. (R. F.)

THEMIS, the Greek mythological personification of custom. In Homer the word occurs both in the singular and in the plural (themistes), with the sense of "custom," "unwritten law." But even in Homer Themis is also spoken of as a goddess who, at the command of Zeus, calls the gods to an assembly and summons or disperses the assemblies of men. But after all she is a thin abstraction, a faint shadow, by the side of the full-blooded gods of Olympus. Hesiod furnished her with a pedigree (making her the daughter of Sky and Earth), and married her to Zeus, by whom she became the mother of a brood of well-bred abstractions,—Legality, Justice, Peace, the Hours, and the Fates. Pindar, no doubt with a full sense of her abstract nature, speaks of her as the assessor of Zeus. In one passage (*Prom.*, 209) Æschylus seems to regard her as identical with Earth, and "Earth-Themis" had a worship and priestess at Athens, where Athene also appears with the surname Themis. There was a tradition that the oracle at Delphi had first been in the hands of Earth, who transferred it afterwards to Themis, who in turn gave it up to Apollo. Themis had temples at Athens, Thebes, Tanagra, and Epidaurus. At Olympia she had an altar, and at Trœzen there was an altar of the Themides (plural of Themis). In modern writers Themis sometimes stands as a personification of law and justice,—an idea much more abstract and advanced than the original sense of "traditional custom."

THEMISTIUS, named εὐφραδής, or "the well-languaged," was a rhetorician and philosopher of the latter half of the 4th century. Of Paphlagonian descent, he settled and taught at Constantinople. Thence he was called to Rome, but, after a short stay in the West, returned to the Eastern capital, where he resided during the rest of his life. Though a pagan, he was admitted to the senate by Constantius in 355. He was prefect of Constantinople in 384 on the nomination of Theodosius. Themistius's paraphrases of Aristotle's *Posterior Analytics*, *Physics*, and *De Anima* are deservedly esteemed; but weariness and disgust are the sentiments stirred by the servile orations in which he panegyrizes successive emperors, comparing first one and then another to Plato's "true philosopher," and, when all other compliments had been exhausted, to the "idea" itself. (See Reiske, quoted with approval by Dindorf in the preface to his edition: "Fuit aulicus adulator et versipellis, vanus jactator philosophiæ suæ, specie magis quam re cultæ, ineptus et ridiculus vexator et applicator Homeri et veteris historiæ, tautologus et sophista; in omnibus orationibus pæne eadem, et ubique argutiæ longe petitæ.") Themistius's paraphrases of the *De Cœlo* and of book Λ of the *Metaphysics* have reached us only through Hebrew versions.

The first edition of Themistius's works (Venice, 1534) included the paraphrases and eight of the orations. Nineteen orations were known to Petavius, whose editions appeared in 1613 and 1618. Harduin (Paris, 1684) gives thirty-three. Another oration was discovered by Angelo Mai, and published at Milan in 1816. The most recent editions are W. Dindorf's of the orations (Leipsic, 1832) and L. Spengel's of the paraphrases (Leipsic, 1866). The Latin translations of the Hebrew versions of the paraphrases of the *De Cœlo* and book Λ of the *Metaphysics* were published at Venice in 1574 and 1558 respectively. See Fabricius, *Bibliotheca Græca*, vi. 790 *sq*.

THEMISTOCLES was born in the latter part of the 6th century B.C., some time during the rule of the Pisistratidæ at Athens, the son of an Athenian father, Neocles, by a foreign woman from Thrace or Caria. A wayward, ambitious, aspiring boy, out of sympathy alike with ordinary boyish amusements and with the learning and culture of the age, he was told, it is said, by his schoolmaster "that he would certainly be something great, whether good or bad." The victory of Marathon in 490 stirred the young man's soul, and he seems to have foreseen that it was but the beginning of a yet greater conflict. He resolved from that time to make his country great, that he might be great and famous himself. As he was rising to political distinction, he had for his rival the Greek "Cato," the incorruptible Aristides, a purer patriot, a better citizen, but a less sagacious and far-seeing statesman. The two men were in sharp antagonism as to what their country's policy should be, and it ended in a vote of ostracism which sent Aristides into temporary banishment in 483. The main question between them probably was whether Athens should seek greatness by sea or by land (see vol. xi. p. 89), and the victory of the policy of Themistocles led on to the most brilliant era in Greek history, the maritime supremacy of Athens. Persia, he felt sure, was meditating a great revenge, and Athens must make herself a naval power to avert the blow. Already a small war with the Æginetan islanders, close to her own shores had roused her energies, and at the prompting of Themistocles she had built 200 ships and trained a number of seamen. In 480 the storm which Themistocles had clearly foreseen burst; the great king, as he was called, was covering the land with his troops and the sea with his ships. Greece was divided and panic-stricken; Thessaly and all to the north of Bœotia had joined the enemy, and the despair of the remainder of the Greek world was echoed by the oracle of Delphi. There was, however, a word of hope in the memorable phrase of the "wooden wall,"[1] which, it was generally felt, must point to the fleet, more, however, with a view to flight than to resistance. Salamis, too, was named in the oracle, coupled with the epithet "divine," which Themistocles cleverly argued portended disaster to the enemies of the Greeks rather than to the Greeks themselves. It was a great achievement when he finally prevailed on his fellow-citizens to quit their city and their homes—it seemed forever—and to trust themselves to their ships. There had been some sea-fights off the northern shores of Eubœa; the Spartans had fallen at Thermopylæ, and Xerxes and his host were now laying waste Attica, not, however, before its inhabitants had conveyed their families to the adjacent island of Salamis, where also the Greek fleet had taken up its station, the Persian armada of 1200 vessels being in harbor at Phalerum. The Athenians from their ships saw the flames in which their city, its acropolis and its temples, were perishing, but their spirits rose with calamity, and with one heart, at the bidding of Themistocles, they called back all of their brethren who were in temporary banishment, Aristides among them. Nearly two-thirds of the entire fleet was theirs, but for the sake of unity among the allies, who would follow only the lead of Sparta, they acquiesced in its being under the command of a Spartan admiral. It was clear, however, that the fate of Greece now depended on the action of the Athenians and on the prudence and ability of Themistocles, by whom they were guided. The Greeks of the Peloponnese, more particularly the Corinthians, were for moving the fleet from Salamis to the isthmus, as the enemy's land forces were already in possession of the neighboring shores of Attica. Seeing the danger of yet further disunion, with the probable result of the breaking up and dispersion of the fleet, and having in vain protested against quitting their present station, Themistocles went straight to the Spartan admiral, Eurybiades, and induced him to call another council. There was much angry debating, till at last the Spartan felt he must yield to the threat of Themistocles that the Athenians would either fight at Salamis or sail away as they were to Italy. But the Peloponnesian Greeks were still dissatisfied, and insisted that they ought to be at the isthmus for the defence of what yet remained of Greece; a third council was held, and Themistocles felt that its decision would be against him, when, by a sudden happy thought, he contrived to have a secret message conveyed to the commanders of the Persian fleet through his slave, an Ionian Greek from Asia, a man of intelligence and education, and well acquainted with the Persian language. The communication came in the name of Themistocles, who professed that he wished well to the king, and now was a good opportunity for attacking and crushing the Greeks, as they were divided among themselves and were bent on flight. The stratagem was successful, and the enemy's great armada advanced along the coast of Attica that same night, and took up a position which effectually confined the Greek fleet within the narrow[2] strait between Salamis and the southern shore of Attica. The Greek captains, not knowing the state of the case, were still wrangling through the night, when just before daybreak the banished Aristides came from Ægina with the news that the Persian fleet was close at hand and that retreat was impossible. "Let us still be rivals," he said to Themistocles, "but let our strife be which can best save our country."

The great victory of Salamis (see vol. xi. p. 90) left Greece mistress of the sea, and was followed by the retreat of Xerxes. Themistocles, it is said, frightened the king back to Asia by another secret message, to the effect that the victorious Greeks were bent on following him up to the Hellespont and burning his bridge of boats, but that he was doing his best to check their ardor, though in reality he had himself advised immediate pursuit of the enemy. We cannot but admire the man's sagacity and far-sightedness in thus laying the king under an obligation which he might some day turn to his own profit, though we cannot but feel that he had some of the worst as well as some of the most splendid characteristics of the Greek. After the victory Themistocles sailed with the Athenian squadron through the Ægean, and from some of the islanders who had sided with the enemy he exacted heavy fines, out of which, it appears, he filled his own purse. When the Greeks met at the isthmus to decide according to custom the prizes of merit for the glorious day of Salamis, he received only the second prize, the first being awarded to the Spartan admiral, but by way of compensation he was soon afterwards heartily welcomed at Sparta, and loaded with honors so extraordinary as to imply that even the Spartans themselves recognized him as the first man in Greece. It was not long, however, before he gave them deadly offence. After the victories of Platæa and Mycale in 479 the Athenians went back to their desolate city and began to rebuild and fortify it. Jealous fears of the growing power of Athens were awakened, and the Spartans, as representatives of the Greeks generally, formally protested against the fortification of a Greek city outside the Peloponnese, on the ground that some future Persian invader might make it a base of operations. Themistocles saw the dangers of Spartan opposition, and got the Athenians to commission him to arrange matters along with two other envoys, who, however, were purposely not allowed to arrive at Sparta at the same time as himself. He told the Spartan magistrates that before he could transact business with them he must wait for his colleagues; meanwhile Athens was being fortified, every man, woman, and child putting a hand to the work, and as soon as Themistocles understood that it was sufficiently advanced he declared openly that Athens would brook no sort of interference. The Spartans felt they had been tricked, but they could do nothing. And now Themistocles proceeded to fortify Piræus, and to enlarge the harbor, thus providing Athens with an excellent naval dockyard, and holding out an inducement to foreigners to settle in the city for the purposes of trade. Twenty war ships, too, were at his suggestion to be built every year, and nothing left undone to make Athens prosperous and powerful.

A few years afterwards (in 471 probably) we find his political career terminated by a vote of ostracism, due perhaps in part to Spartan influence at Athens, and also to an offensive boastfulness and ostentation which disgusted the sensitive Athenian democracy. He was even charged with corrupt practices and with receiving bribes from Persia. From Argos, whither he had retired as an exile, he was forced to flee by a threat of the Spartans, who alleged that they had proofs of his treasonable complicity in the schemes of their countryman Pausanias, and to take refuge in the island of Corcyra; but here again he was pursued by Spartan and Athenian commissioners, and driven to seek the protection of Admetus, king of the Molossians, the chief people of Epirus. In the court of this half-Greek half-barbarian prince he found a hospitable reception, and he was furnished with the means of crossing the Ægean to Ephesus. Shortly after his arrival in Asia, the son of Xerxes, Artaxerxes, succeeded to the throne of Persia, and to him Themistocles contrived to make himself known as a fugitive from ungrateful Greece, which he had saved, and now ready and willing to advise and assist the king in avenging his father's defeat. He was treated, it is said, with marked respect, and was liberally pensioned with the revenues of three wealthy towns—Magnesia, Myus, and Lampsacus. It was at the first of these, which was near the coast, and whence he might be supposed to have opportunities for watching the affairs of Greece, that he passed the last year of his life, dying a natural death at the age of 65. The year of his death is not accurately ascertainable; opinions vary between 460 and 447.

[1] "The wooden wall shall alone remain unconquered to defend you and your children."

[2] Not more than a quarter of a mile wide in its narrowest part.

Herodotus, Thucydides, and Plutarch are our chief original sources for the life of Themistocles. The subject is fully treated in the histories of Grote and Thirlwall. (W. J. B.)

THÉNARD, Louis Jacques (1777–1857), was born on the 4th of May, 1777, at Louptière, near Nogent-sur-Seine, in Champagne. His father, though a poor man, sent him to the academy of Sens, where he received a liberal education. At the age of sixteen he went to Paris to study pharmacy. He attended the lectures of Fourcroy and Vauquelin, and saw that the only way to learn chemistry was to work at it. Vauquelin, himself a poor man, admitted a few students to his laboratory on payment of a fee of 20 francs a month. But this fee was prohibitory to the peasant's son; the utmost that his father could send him just kept him alive in Paris. Thénard went to Vauquelin and asked to be allowed to do any menial work for him, if only he would let him assist in his laboratory. One of Vauquelin's sisters had slipped into the room and heard part of the conversation; she said to her brother, "He is a good lad; you should keep him; he will help you in the laboratory, and look after our *pot au feu;* your dandy assistants always let it boil." Thénard was engaged on these terms. Long afterwards he said that he looked upon the chemistry of the *pot au feu* and the process of simmering as of very great importance: they had been the turning-point of his life. Thénard assisted Vauquelin in the laboratory and at his lectures, and, when by starving for a day or two he accumulated sous enough to pay for a seat in the gallery, used to go to the theatre to improve his pronunciation and rub off his rustic accent.

By and by Vauquelin gave him an opportunity of testing his powers as a lecturer. Having to go for some days to the country, he asked Thénard to take his place. For the first two or three lectures his attention was fixed on his work, and his eyes did not wander from the lecture table. On the fifth day he ventured to look round the room, when to his consternation he saw Fourcroy and Vauquelin among the audience. They were so satisfied with what they had heard that they obtained for Thénard in 1797 an appointment as teacher of chemistry in a school, and in 1798 the post of repétiteur at the École Polytechnique.

In 1804 Vauquelin resigned the professorship of chemistry at the Collége de France, and successfully used his influence to have Thénard appointed. In 1810 he succeeded Fourcroy both as professor of chemistry at the Ecole Polytechnique and as member of the Academy. He was also appointed professor of chemistry in the faculty of the sciences. He was made a chevalier of the Legion of Honor in 1814, commander in 1837, and grand officer in 1842. In 1825 Charles X. gave him the title of baron; from 1827 to 1830 he represented the department of Yonne in the chamber of deputies. In 1832 Louis Philippe made him a peer of France. As vice-president of the conseil supérieure de l'instruction publique, he exercised a great influence on scientific education in France. He died 21st June, 1857, and was buried at La Ferte, near Châlon-sur Saône. In 1861 a statue was erected to him at Sens, and in 1865 the name of his native village was changed to La Louptière-Thénard. Thénard was tall and strongly built, his hair was thick and black, his eyes bright, and his manner active and prompt. He married, in 1810, Mlle. Humblot, granddaughter of Conté. His wife and several of his children predeceased him. He was survived by his son Paul, who had assisted him in some of his later researches.

Thénard was above all things a teacher: as he himself said, the professor, the assistants, the laboratory, everything, must be sacrificed to the students. The history of his discovery of the peroxide of hydrogen well illustrates the predominance of the teacher in his character. He was lecturing on the formation of salts, and had told his students that a metal must be oxidized to a certain extent in order that it may combine with an acid to form a salt; if the metal be combined with more than the proper quantity of oxygen, the excess of oxygen will be given off when the oxide is treated with an acid, and, as an illustration, he mentioned the action of acids on peroxide of barium. As he spoke his conscience smote him, for the experiment had not been made. Immediately after lecture he mixed peroxide of barium and nitric acid, keeping the temperature low by means of ice. He was surprised to see the peroxide dissolve without any evolution of gas. He left the mixture standing, and next day, before lecture, noticed small bubbles of gas rising from it. Pouring some of the liquid into a test-tube and warming it, he saw a large amount of gas escape, which he easily recognized as pure oxygen. At first he thought the acid had been oxidized, but he soon saw the true explanation of the phenomena, and discovered the peroxide of hydrogen. His lecture experiments were few, well-chosen, and accurately performed. If any failure occurred he would roundly scold his assistant, often apologizing for his vehemence when the short fit of anger was over. His lecture room, seated for 1000, was almost always crowded by eager and attentive students and visitors.

Like most great teachers, Thénard published a text-book, and perhaps we may say that by his *Traité de Chimie Élémentaire, Théorique et Pratique* (4 vols., Paris, 1813–16; 6th ed., 5 vols., 1833–36) he did even more to further the progress of the science than by his numerous and important original discoveries. His first original paper (1799) was on the compounds of arsenic and antimony with oxygen and sulphur. Careful analysis led him to conclusions as to the composition of the metallic oxides contradictory of some of Berthollet's theoretical views; he also showed (1802) that Berthollet's "zoonic acid" was impure acetic acid. Berthollet, far from resenting these corrections from a younger man, took this opportunity of introducing himself, and invited Thénard to become a member of the "Société d'Arcueil," to the proceedings of which Thénard contributed important papers. Soon after his appointment as repétiteur at the École Polytechnique Thénard made the acquaintance of Gay-Lussac, and formed with him a lifelong friendship. Their joint work, and its relation to the discoveries of Davy, have been fully recorded in the article Gay-Lussac. Of his separate investigations perhaps the most important is that on the compound ethers, begun in 1807. He showed that each acid gives its own ether, and that the acid and alcohol can be recovered by decomposing the ether by means of caustic alkali. His discovery of peroxide of hydrogen (1818) has already been described. His researches on sebacic acid (1802) and on bile (1807) also deserve special notice. The blue substance known as Thénard's blue (essentially aluminate of cobalt) was prepared by him in response to a demand by Chaptal for a cheap blue, as bright as ultramarine, and capable of standing the temperature of the porcelain furnace.

Thénard's researches were chiefly published in the *Annales de Chimie et de Physique*, in the *Mémoires de la Société d'Arcueil*, and in the *Comptes Rendus* and the *Mémoires* of the Academy of Sciences. (A. C. B.)

THEOBALD, Lewis (1688–1744), will survive as the prime butt of the original *Dunciad* when as a playwright, a littérateur, a translator, and even as a Shakespearean commentator, he will be entirely forgotten. The son of an attorney, Theobald was born at Sittingbourne, in Kent, in 1688, and after a moderate education at Isleworth, studied for the profession of law,—a profession, however, which he never practiced. He was a man with literary impulses, but without genius, even of a superficial kind; as a student, as a commentator, he might have led a happy and enviable life, had not the vanity of the literary idea led him into a false position. His *Persian Princess* (1711) and his *Electra* (1714) gained no distinction. In 1726 *The Double Falsehood* had a certain vogue, partly from Theobald's pretence that the greater part of the play was by Shakespeare. In 1717 he commenced a series of papers (not to "The Censor," as has sometimes been stated, but under that title) which appeared in Mist's *Weekly Journal;* these do not seem to have been highly thought of by his contemporaries, but they were successful in gaining for Theobald not a few enemies, among whom Dennis may be named. Seven or eight years later Theobald's censorious tendencies had intensified rather than moderated, and in 1726 he ventured to attack the most eminent literary men of the day in his *Shakespeare Restored, or a Specimen of the many Errors as well committed as unamended by Mr. Pope in his edition of this Poet.* Two years later the censor was himself castigated severely, and, as the dedicatee of *The Dunciad*, he had long an unenviable notoriety; as readers of the famous satire will remember, he occupied the place of chief victim until replaced by Colley Cibber in 1743. In the matter of Shakespeare editing, however, he had the advantage of his powerful rival. When in 1733 Theobald published his edition of Shakespeare in seven volumes, that of Pope had to go to the wall. Lewis Theobald wrote other dramas besides those already mentioned, and translated plays from Sophocles and Aristophanes, besides a rendering of Plato's *Phædo* and a part translation of the *Odyssey*; but for none of these things is he now remembered. The student of English history might find it worth while to glance through Theobald's *Life of Raleigh* (1719). He died in 1744.

For plays, etc., see the *Biographia Dramatica*, vol. i.

THEOCRITUS, of Syracuse, the foremost Greek pastoral poet, lived a life of which nothing is known except from allusions in his own works. The epigram appended to his poems makes him say, "I am a Syracusan, a man of the people, a son of Praxagoras and Philinna." He must have been born early in the 3d century, among a Dorian people, whose Dorian speech survives in his rural idyls. These "little pictures" chiefly represent the life of shepherds, neatherds, and fishermen in the woods and on the shores of Sicily. They are doubtless inspired by the popular poetry of his time, and have much in common with the Romaic chants of the modern Greek shepherds. The first idyl is a song on Daphnis, the ideal herdsman, sung by the shepherd Thyrsis to a goatherd. The second is the magical chant which Simætha pours forth to the magic moon, in the hope of recovering her lover. In the third a goatherd sings to his love, Amaryllis. The fourth is an interchange of rude banter between two country fellows; and the fifth is of the same kind. The scenes are in southern Italy. The sixth is a Sicilian singing match between two ideal herdsmen,—not contemporary rustics, but poets of nobler themes. The scene of the seventh is in Cos, where the poet introduces himself at a singing match. He may have been attached to the Asclepian medical school in Cos; his friend Nicias was a physician. Sicily and rival minstrels occupy the ninth idyl. The tenth contains probably some real popular ditties, chanted by the reapers. The eleventh, addressed to Nicias, is a piece of artificial mythological *genre*, "The Cyclops in Love." The twelfth is a lyric, almost of passionate affection. The thirteenth is another idyl on a mythical topic, the adventures of Hercules and Hylas. The fourteenth and fifteenth are sketches of military and urban life, the mercenary soldier in love, and the gathering at the Adonis feast in Alexandria. Theocritus had wandered to the court of Ptolemy, and joined the literary society of his court. The sixteenth is a patriotic piece: the poet urges Hiero to assail the Carthaginians in Sicily. The seventeenth is a conventional hymn to Ptolemy Philadelphus on his marriage with his sister. The eighteenth is an epithalamium; the nineteenth a tiny picture of Eros stung by a bee; the twentieth is the complaint of a herdsman rejected by a girl of the town; the twenty-first an idyl of fisher life: two poor old fishermen recount their dreams. The twenty-second idyl is a piece of heroic myth, the adventures of Castor and Polydeuces; and the twenty-fourth is a tiny epic on the infancy of Hercules. The twenty-third is an amorous complaint. The twenty-fifth describes the slaughter by Hercules of the Nemean lion. The twenty-sixth justifies, in the interest of the ritual of Dionysus, the murder of the curious Pentheus. The twenty-seventh is the "Wooing of Daphnis," or "Oaristys," an amorous discourse between a girl and a swain. The twenty-eighth is a graceful piece of *vers de société*, sent to a lady with the gift of an ivory distaff. The twenty-ninth is amorous; and there remain an imperfect and a spurious piece, and a set of twenty-three epigrams.

On a general view, Theocritus's surviving poems turn out to be—(1) rural idyls, the patterns of Virgil's eclogues, and of all later pastoral poetry; (2) minute epics, or cabinet pictures from mythology; (3) sketches of contemporary life in verse; (4) courtly compositions; and (5) expressions of personal kindliness and attachment. The first category and the third are those on which the fame of Theocritus depends. His verse has a wonderful Doric melody; his shepherds are natural Southern people: it is not his fault that what he wrote truly of them has become a false commonplace in the pastoral poetry of the North.

Of Theocritus's own life we only know what has been recorded, that he lived in Syracuse, Cos, and Alexandria, and that he was acquainted with Nicias, with Aratus, the astronomical writer, and with Philinus, head of a school or sect of physicians. The rest is silence or conjecture. Suidas says that, in addition to the surviving poems, the *Prœtidæ*, the *Hopes*, *Hymns*, the *Heroines*, *Dirges*, *Elegies*, and *Iambics* were attributed to him.

The charm of Theocritus can only be tasted in his original Doric, but the best English version is by Mr. C. S. Calverley. M. Couat's book on the Alexandrine school of poetry may be recommended. J. Hauler, *De Theoc. Vita et Carminibus* (Freiburg, 1855), Hempel, *Quæst. Theoc.* (Kiel, 1881), and Rannow, *Studia Theocritea* (Berlin, 1886), may also be found useful. The best English edition of the poems is that of Bishop Wordsworth. (A. L.)

THEODOLITE. See SURVEYING.

THEODORA, the wife of the emperor JUSTINIAN (*q.v.*), was born probably in Constantinople, though according to some in Cyprus, in the early years of the 6th century, and died in 547. We shall first give the usually received account of her life and character, and then proceed to inquire how far this account deserves to be accepted. According to Procopius, our chief, but by no means a trustworthy authority for her life, she was the daughter of Acacius, a bear-feeder of the amphitheatre at Constantinople to the Green Faction, and while still a child was sent on to the stage to earn her living in the performances called mimes. She had no gift for either music or dancing, but made herself notorious by the spirit and impudence of her acting in the rough farces, as one may call them, which delighted the crowd at the capital. Becoming a noted courtesan, she accompanied a certain Hecebolus to Pentapolis (in North Africa), of which he had been appointed governor, and, having quarrelled with him, betook herself first to Alexandria, and then back to Constantinople through the cities of Asia Minor. In Constantinople (where, according to a late but apparently not quite groundless story, she now endeavored to support herself by spinning, and may therefore have been trying to reform her life) she attracted the notice of Justinian, then patrician, and, as the all powerful nephew of the emperor Justin, practically ruler of the empire. He desired to marry her, but could not overcome the opposition of his aunt, the empress Euphemia. After her death (usually assigned to the year 523) the emperor yielded, and, as a law, dating from the time of Constantine, forbade the marriage of women who had followed the stage, with senators, this law was repealed. Thereupon Justinian married Theodora, whom he had already caused to be raised to the patriciate. They were some time after (527) admitted by Justin to a share in the sovereignty; and on his death four months later, Justinian and Theodora became sole rulers of the Roman world. He was then about forty-four years of age, and she some twenty years younger. Procopius relates in his unpublished history ('Ανέκδοτα) many repulsive tales regarding Theodora's earlier life, but his evident hatred of her, though she had been more than ten years dead when the *Anecdota* were written, and the extravagances which the book contains, oblige us to regard him as a very doubtful witness. Some confirmation of the reported opposition of the imperial family to the marriage has been found in the story regarding the conduct of Justinian's own mother Vigilantia, which Nicolas Alemanni, the first editor of the *Anecdota*, in his notes to that book, quotes from a certain "Life of Justinian" by Theophilus, to which he frequently refers, without saying where he found it. Since the article JUSTINIAN (*q.v.*) was published, the present writer has discovered in Rome what is believed to be the only MS. of this so-called life of Justinian; and his examination of its contents, which he has lately published, makes him think it worthless as an authority. See article THEOPHILUS.

Theodora speedily acquired unbounded influence over her husband. He consulted her in everything, and allowed her to interfere directly, as and when she pleased, in the government of the empire. She had a right to interfere, for she was not merely his consort, but empress regnant, and as such entitled equally with himself to the exercise of all prerogatives. In the most terrible crisis of Justinian's reign, the great Nika insurrection of 532, her courage and firmness in refusing to fly when the rebels were attacking the palace saved her husband's crown, and no doubt strengthened her command over his mind. Officials took an oath of allegiance to her as well as to the emperor (*Nov.*, viii.). She even corresponded with foreign ambassadors, and instructed Belisarius how to deal with the popes. Procopius describes her as acting with harshness, seizing on trivial pretexts persons who had offended her, stripping some of their property, throwing others into dungeons, where they were cruelly tortured or kept for years without the knowledge of their friends. The city was full of her spies, who reported to her everything said against herself or the administration. She surrounded herself with ceremonious pomp, and required all who approached to abase themselves in a manner new even to that half-Oriental court. She was an incessant and tyrannical match-maker, forcing men to accept wives and women to accept husbands at her caprice. She constituted herself the protectress of faithless wives against outraged husbands, yet professed great zeal for the moral reformation of the city, enforcing severely the laws against vice, and immuring in a "house of repentance" on the Asiatic side of the Bosphorus five hundred courtesans whom she had swept out of the streets of the capital. How much of all this is true we have no means of determining, for it rests on the sole word of Procopius. But there are slight indications in other writers that she had a reputation for severity.

In the religious strife which distracted the empire Theodora took part with the Monophysites, and her coterie usually contained several leading prelates and monks of that party. As Justinian was a warm upholder of the decrees of Chalcedon, this difference of the royal pair excited much remark and indeed much suspicion. Many saw in it a design to penetrate the secrets of both ecclesiastical factions, and so to rule more securely. In other matters also the wife spoke and acted very differently from the husband; but their differences do not seem to have disturbed either his affection or his confidence. The maxim in Constantinople was that the empress was a stronger and a safer friend than the emperor; for, while he abandoned his favorites to her wrath, she stood by her protégés, and never failed to punish any one whose heedless tongue had assailed her character.

Theodora bore to Justinian no son, but one daughter,—at least it would seem that her grandson, who is twice mentioned, was the offspring of a legitimate daughter, whose name, however, is not given. According to Procopius, she had before her marriage become the mother of a son, who when grown up returned from Arabia, revealed himself to her, and forthwith disappeared for ever; but this is a story to be received with distrust. That her behavior as a wife was irreproachable may be gathered from the fact that Procopius mentions only one scandal affecting it, the case of Areobindus. Even he does not seem to believe this case, for, while referring to it as a mere rumor, the only proof he gives is that, suspecting Areobindus of some offence, she had torture applied to this supposed paramour. Her health was delicate, and, though she took all possible care of it, frequently quitting the capital for the seclusion of her villas on the Asiatic shore, she died comparatively young. Theodora was small in stature and rather pale, but with a graceful figure, beautiful features, and a piercing glance. There remains in the apse of the famous church of St. Vitale at Ravenna a contemporaneous mosaic portrait of her, to which the artist, notwithstanding the stiffness of the material, has succeeded in giving some character.

The above account is in substance that which historians of the last two centuries and a half have accepted and repeated regarding this famous empress. But it must be admitted to be open to serious doubts. Everything relating to the early career of Theodora, the faults of her girlhood, the charges of cruelty and insolence in her government of the empire, rest on the sole authority of the *Anecdota* of Procopius,—a book whose credit is shaken by its bitterness and extravagance. If we reject it, little is left against her, except of course that action in ecclesiastical affairs which excited the wrath of Baronius, who had denounced her before the *Anecdota* were published.

In favor of the picture which Procopius gives of the empress it may be argued (1) that she certainly did interfere constantly and arbitrarily in the administration of public affairs, and showed herself therein the kind of person who would be cruel and unscrupulous in her choice of means, and (2) that we gather from other writers an impression that she was harsh and tyrannical, as, for instance, from the references to her in the lives of the popes in the *Liber Pontificalis* (which used to pass under the name of Anastasius, the papal librarian). Her threat to the person whom she commanded to bring Vigilius to her was "nisi hoc feceris, per Viventem in sæcula excoriari te faciam." Much of what we find in these lives is legendary, but they are some evidence of Theodora's reputation. Again (3) the statute (*Cod.* v. 4, 23) which repeals the older law so far as relates to *scenicæ mulieres* is now generally attributed to Justin, and agrees with the statement of Procopius that an alteration of the law was made to legalize her marriage. There is therefore reason for holding that she was an actress, and, considering what the Byzantine stage was (as appears even by the statute in question), her life cannot have been irreproachable.

Against the evidence of Procopius, with such confirmations as have been indicated, there is to be set the silence of other writers, contemporaries like Agathias and Evagrius, as well as such later historians as Theophanes, none of whom repeat the charges as to Theodora's life before her marriage. To this consideration no great weight need be attached. It is difficult to establish any view of the controversy without a long and minute examination of the authorities, and in particular of the *Anecdota*. But the most probable conclusions seem to be—(1) that the odious details which Procopius gives, and which Gibbon did not blush to copy, deserve no more weight than would be given nowadays to the malignant scandal of disappointed courtiers under a despotic government, where scandal is all the blacker because it is propagated in secret (see PROCOPIUS); (2) that apparently she was an actress and a courtesan, and not improbably conspicuous in both those characters; and (3) that it is impossible to determine how far the specific charges of cruelty and oppression brought against her by Procopius deserve credence. We are not bound to accept them, for they are uncorroborated; yet the accounts of Justinian's government given in the *Anecdota* agree in too many respects with what we know *aliunde* to enable us to reject them altogether; and it must be admitted that there is a certain internal consistency in the whole picture which the *Anecdota* present of the empress. About the beauty, the intellectual gifts, and the imperial will of Theodora there can be no doubt, for as to these all our authorities agree. She was evidently an extraordinary person, born to shine in any station of life.

Her fortunes have employed many pens. Among the latest serious works dealing with them may be mentioned M. Antonin Débidour's *L'Impératrice Theodora; Étude Critique*, Paris, 1885, which endeavors to vindicate her from the aspersions of Procopius; and among more imaginative writings are Sir Henry Pottinger's interesting romance *Blue and Green* (London, Hurst and Blackett, 1879), M. Rhangabé's tragedy Θεοδωρα (Leipsic, 1884), and M. Sardou's play *Theodora*, produced in Paris in 1884. See also Dr. F. Dahn's *Prokopios von Cäsarea*, 1865. (J. BR.)

THEODORE OF MOPSUESTIA, the most eminent representative of the so-called school of Antioch, the beginnings of which date from about the middle of the 3d century (see LUCIAN and PAUL OF SAMOSATA). He was born at Antioch about the middle of the 4th century, and was a friend of Chrysostom; in rhetoric the celebrated Libanius was his teacher. Soon, however, he attached himself to the school of the great exegete and ascetic, Diodorus, a presbyter in Antioch, and, with only a transitory period of vacillation, he ever afterwards remained faithful to the theology and ascetic discipline of this master. Under Diodorus he became a skilful exegete, and ultimately the pupil outstripped the master in Biblical learning. About 383 Theodore became a presbyter in Antioch, and began to write against Eunomius the Arian and against the christology of Apollinaris. Soon after 392 he became bishop of Mopsuestia in Cilicia (the modern Missis near Adana). As such he was held in great respect, and took part in several synods, with a reputation for orthodoxy that was never questioned. It was greatly to his advantage that in the Eastern Church the period between the years 390 and 428 was one of comparative repose. He was on friendly terms even with Cyril of Alexandria. He died in 428 or 429, towards the beginning of the Nestorian controversy.

Theodore was a very prolific writer, but, before all, an exegete. He wrote commentaries on almost every book of the Old and New Testaments, of which, however, only a small proportion is now extant, as at a later period he lost credit in the church. We still possess in Greek his commentary on the Minor Prophets, and in Latin translations commentaries on the minor Pauline epistles, besides very many fragments, especially of that on the epistle to the Romans. Theodore's importance as an exegete lies in two characteristics: (1) in opposition to the allegorical method he insists on getting at the literal meaning, and adheres to it when found; (2) in his interpretation of the Scriptures he takes into account the historical circumstances in which they were produced, and substitutes the historical-typological for the pneumatico-christological interpretation of prophecy; in other words, he interprets all Old Testament passages historically in the first instance, and sees the fulfilment of Old Testament prophecy in the history of Christ and His church only in so far as the entire Old Testament is a "shadow of things to come." Following his master Diodorus, who had already written a treatise Τίς διαφορὰ θεωρίας καὶ ἀλληγορίας, Theodore also was the author of a special dissertation against the allegorists, *i.e.*, against Origen and his followers, which, however, has unfortunately perished. The comparative freedom of Theodore's view of inspiration is also noteworthy. He discriminates between historical, prophetical, and didactic writings, and in accordance with this distinction assumes varying degrees of inspiration. Finally, he entertained very bold opinions about the canon and several of the books included in it. He esteemed very lightly the Solomonic writings and the book of Job: Canticles he explained as a nuptial poem of Solomon's; the book of Job appeared to him in many places hardly worthy of its subject, and he censures the writer sharply; Chronicles, Ezra, and Nehemiah he entirely rejected; he denied the accuracy of the titles of the Psalms, and referred the so-called Messianic element almost invariably to the kings of Israel; he even criticised the catholic epistles and rejected the epistle of James. His commentaries contain a great deal of learned matter, and his grammatico-historical observations are still to some extent useful. But, on the other hand, his learning must not be overestimated. It falls behind that of Origen, Eusebius, and Jerome, notwithstanding the superiority of his method. It is specially noticeable that Theodore troubled himself little about textual criticism. He simply accepts the text of the LXX. as that of revelation, and never manifests the slightest effort to control it by the original or by the Syriac.

But in addition to his commentaries Theodore also wrote extensive dogmatico-polemical works, which were destined to operate long after his death disastrously for his fame. As a disciple of Diodorus, Theodore accepted the Nicene teaching on the doctrine of the Trinity, but at the same time in christology took up a position very closely approaching that of Paul of Samosata. The violence of his opposition to his fellow-countryman, Apollinaris of Laodicea, perhaps the most acute and far-seeing theologian of the century, made it necessary for Theodore to formulate his christology with precision (in fifteen books on the Incarnation—all lost except a few fragments—and in special treatises against Apollinaris). He held the Logos to have assumed a complete manhood, which had to pass through the stages of ethical development just as in the case of any other human being. In this the Logos only supported the man Christ Jesus, but was not essentially connected with him; the Logos dwelt in him (ἐνοικεῖν), but any such thing as ἕνωσις φυσική did not and could not exist, because the finite is not "capax infiniti," and because any ἕνωσις would have destroyed the reality of the human nature. The same sober and thoughtful way of looking at things, and the same tendency to give prominence to the moral element, which characterize the commentaries of Theodore appear also in his dogmatic. When, accordingly, the Nestorian controversy broke out, his works also were dragged into the discussion. At Ephesus, indeed, the memory of Theodore does not appear to have been attacked,[1] but soon afterwards the assault began. Marius Mercator, Rabulas of Edessa, Cyril, and other monophysites brought the charge of heresy against his writings, and sought to counteract their influence. But it was not until more than a century afterwards that his fanatical adversaries succeeded—in spite of the strong opposition of the best theologians of the West—in obtaining from Justinian the condemnation of his works in the controversy of the Tria Capitula, as it is called; this act of the emperor was confirmed by the fifth œcumenical council, and Theodore's name was accordingly deleted from the list of orthodox writers. From that day Theodore's works ceased to be read within the Byzantine Church, and hence have been lost. The Syrians, on the other hand, have always held in high esteem the memory of the great teacher, and have even carried back their liturgy to his name. The Nestorians possess, or possessed, a very large number of writings by him in Syriac translations.[2]

Theodore took part also in the Pelagian controversy at the time when it raged in Palestine. In the treatise, only partially preserved,[3] Πρὸς τοὺς λέγοντας φύσει καὶ οὐ γνώμῃ πταίειν τοὺς ἀνθρώπους, he sharply controverts the doctrine of original sin and Jerome its advocate. In his view the theory of Augustine is "a new heresy," "a malady"; he regarded it as a doctrine which necessarily led to dualism and Manichæism. The attitude thus taken by Theodore is not surprising; he more nearly takes up the ground of the old church doctrine as set forth in the apologists and in the great Greek fathers of the 3d and 4th centuries. The Pelagians driven from the East were received by him in Cilicia.

A brother of Theodore, Polychronius by name, bishop of Apamea, also achieved fame as an exegete, and expounded the theology of the school of Antioch.[4]

Literature.—Migne, *Patrol.*, ser. Gr., lxvi. The Greek fragments of Theodore's New Testament commentaries have been collected by Fritzsche (*Theod. Mops. in N. T. Comm.*, Turin, 1847). The commentaries on the Pauline epistles (Pitra, *Spic. Solesm.*, i. 49 *sq.*) have been recognized by Jacobi (*Ztschr. f. christl. Wissensch.*, 1854) and Hort (*Journ. Class. and Sacr. Philol.*, iv., 1859, p. 302 *sq.*), and edited by Jacobi (Halle University, *Programm*, 1855–60). They have also been edited very admirably by Swete (*Theod. Mops. in Epp. B. Pauli Comm.*, i., ii., Cambridge, 1880–82), along with the Greek fragments and the fragments of the dogmatical writings, on this edition, see Schürer, *Theol. Lit. Ztg*, 1880–82. The commentary on the Minor Prophets will be found in Mai's *Nov. Patr. Biblioth.*, vii. 1854 (Wegnern, Berlin, 1834; Mai, *Script. Vet. Nov. Coll.*, vi. 1832). See also Sachau, *Theod. Mops. Fragm. Syriaca*, Leipsic, 1869, and Bäthgen, "Der Psalmencommentar des Theod. v. Mops. in Syr. Bearbeitung," in *Ztschr. f. ATliche Wissensch*, v. 53 *sq.* Extracts from the writings of Theodore occur in the *Catenæ* of Marius Mercator, in the *Acta* of the third and fifth œcumenical councils, in Facundus, Liberatus, and Theodore's chief adversary, Leontius Byzantinus.

The principal monograph on Theodore, apart from the excellent prolegomena of Swete, is that of Kihn (*Th. v. Mops. u. Junilius Afric. als Exegeten*, Freiburg, 1880). On his importance for the history of dogma, see the great works of Baur and Dorner. Upon the Antioch school in general, compare Münscher, *Comment. de Schola Antioch.*, Copenhagen, 1811; Hergenröther, *Die antioch. Schule*, 1866; and Kihn, *Die Bedeutung der antioch. Schule*, Eichstädt, 1866. Literary and biographical details will be found in Dupin, Tillemont, Cave, Fabricius, Noris, Garnier, Schröckh, Alzog; see also Fritzsche, *De Theod. Mops. Vita et Scriptis*, 1836; Sieffert, *Theod. Mops. Vet. Test. Sobrie Interpr. Vind.* Ratisbon, 1827; Kiener, *Symbol. Lit. ad. Theod. M. pertin.*, Göttingen, 1836; Specht, *Theod. v. Mops. u. Theodoret*, Munich, 1871; Kihn in the *Tüb. Quartalschr.*, 1879; Nestle in *Theol. Stud. aus Würtemb.*, ii. 210 *sq.*; and Batiffol, "Sur une Traduction Latine de Th. de Mops.," in *Ann. de Philos. Chrét.*, 1885. (A. HA.)

THEODORE, the name of two popes. Theodore I., pope from November, 642, till May, 649, succeeded John IV. He was the son of a bishop, and was born in Jerusalem. A zealous opponent of monothelitism, in the course of the protracted controversy he in a Roman synod excommunicated Pyrrhus, patriarch of Constantinople, and signed the document with ink mingled with consecrated wine. Theodore II. had a pontificate of only twenty days (Nov.–Dec., 897).

THEODORET, bishop of Cyrus, and an important writer in the domains of exegesis, dogmatic theology, church history, and ascetic theology, was born in Antioch, Syria, about 390. At an early age he entered the cloister; and in 423 he became bishop of Cyrus, or Cyrrhus, a small city between Antioch and the Euphrates, where, except for a short period of exile, he spent all the rest of his life. The date of his death is uncertain, but it must have been at least six or seven years later than the council of Chalcedon (451). Although thoroughly devoted to the ideals of monasticism, he discharged his episcopal duties with remarkable zeal and fidelity. He was diligent in the cure of souls, laboring hard and successfully for the conversion of the numerous Gnostic communities and other heretical sects which still maintained a footing within the diocese. He himself claims to have brought more than a thousand Marcionites within the pale of the church, and to have destroyed many copies of the *Diatessaron* of Tatian, which were still in ecclesiastical use; and he also exerted himself to improve the diocese, which was at once large and poor, by building bridges and aqueducts, beautifying the town, and similar works.

As an exegete Theodoret belongs to the Antiochene school, of which Diodorus of Tarsus and Theodore of Mopsuestia were the heads. He was not actually the personal disciple of either, but he adopted their methods, though without the consistency and boldness of the first-named. His extant commentaries (those on Canticles, on the Prophets, on the book of Psalms, and on the Pauline epistles—the last the most valuable) are among the best performances of the fathers of the church. They are brief, yet not wanting in that element of practical edification on which Chrysostom lays special weight as characteristic of the Antiochenes. In addition to these complete commentaries, we have fragments of some others (of that on Isaiah, for example), principally met with in catenæ. There are also special elucidations of some difficult Scripture texts.

Theodoret's chief importance is as a dogmatic theologian, it having fallen to his lot to take part in the great monophysite-Nestorian controversy and to be the most considerable opponent of the views of Cyril and Dioscurus of Alexandria. For more than twenty years he maintained the struggle against the Alexandrian dogmatic and its formulæ (*θεοτόκος ἕνωσις καθ' ὑπόστασιν, μία ὑπόστασις, ἕνωσις φυσική*, and the like), and taught that in the person of Christ we must strictly distinguish two natures (*hypostases*), which are united indeed in one person (*prosopon*), but are not amalgamated in essence. For these years his history coincides with that of the Eastern Church from 430 to 451, and for this very reason it is impossible to sketch it even briefly here (see Hefele, *Conc.-gesch.*, vol. ii.). The issue was not unfavorable to Theodoret's cause, but melancholy enough for Theodoret himself: the council of Chalcedon condemned monophysitism indeed, but he unhappily yielded to pressure so far as also to take part in pronouncing "anathema upon Nestorius, and upon all who call not the Holy Virgin Mother of God, and who divide the one Son into two." As Theodoret had previously been a constant defender of Nestorius, it was impossible for him to concur in this sentence upon his unfortunate friend with a clear conscience, and in point of fact he did not change his own dogmatic position. It is distressing, therefore, to find him in his subsequent *Epitome* classing Nestorius as a heretic, and speaking of him with the utmost hostility. Some of Theodoret's dogmatic works are no longer extant: of his five books Περὶ ἐνανθρωπήσεως, for example, directed against Cyril after the council of Ephesus, we now possess fragments merely. A good deal of what passes under his name has been wrongly attributed to him. Certainly genuine are the refutation (Ἀνατροπή) of Cyril's twelve ἀναθεματισμοί of Nestorius, and the Ἐρανίστης, or Πολύμορφος (written about 446), consisting of three dialogues, entitled respectively Ἄτρεπτος, Ἀσύγχυτος, and Ἀπαθής, in which the monophysitism of Cyril is opposed, and its Appollinarian character insisted on. Among the apologetico-dogmatic works of Theodoret must be reckoned his ten discourses Περὶ προνοίας.

Theodoret gives a valuable exposition of his own dogmatic in the fifth book of his Αἱρετικῆς κακομυθίας ἐπιτομῆς, already referred to.[1] This, the latest of his works in the domain of church history (it was written after 451), is a source of great though not of primary importance for the history of the old heresies. In spite of the investigations of Volkmar and Hilgenfeld, we are still somewhat in the dark as to the authorities he used. The chief uncertainty is as to whether he knew Justin's *Syntagma*, and also as to whether he had access to the *Philosophumena* of Hippolytus in their complete form. Besides this work Theodoret has also left us a church history in five books from 324 to 429, which was published shortly before the council of Chalcedon. The style is better than that of Socrates and Sozomen, as Photius has remarked, but as a contribution to history the work is inferior in importance. It is probable that its author was acquainted with the labors of Socrates; he appears also to have used those of Philostorgius the Arian, but not those of Sozomen. Something indeed still remains to be cleared up as to the sources he employed; apart, however, from some documents he has preserved, relating to the Arian controversy, he does not contribute much that is not to be met with in Socrates. He made a thorough study of the writings of Athanasius for the work. As regards chronology he is not very trustworthy; on the other hand, his moderation towards opponents, not excepting Cyril, deserves recognition. The Ἑλληνικῶν θεραπευτική παθημάτων (*De Curandis Græcorum Affectionibus*)—written before 438—is of an historical and apologetic character, very largely indebted to Clement of Alexandria and Eusebius; it aims at showing the advantages of Christianity as compared with Hellenism, and deals with the assaults of pagan adversaries The superiority of the Christian faith both philosophically and ethically is set forth, the chief stress being laid on monachism, with which heathen philosophy has nothing to compare. Much prominence is also given to the cult of saints and martyrs.

On this side of his character, however, Theodoret can best be studied in the thirty ascetic biographies of his Φιλόθεος ἱστορία. This collection, which has been widely read, is a pendant to the *Historia Lausiaca* of Palladius and the monkish tales of Sozomen. For the East it has had the same importance as the similar writings of Jerome, Sulpicius, Severus, and Cassianus for the West. It shows that the "sobriety" of the Antiochene scholars can be predicated only of their exegesis; their style of piety was as exaggerated in its devotion to the ideals of monasticism as was that of their monophysite opponents. Indeed, one of the oldest leaders of the school, Diodorus of Tarsus, was himself among the strictest ascetics.

Nearly 200 letters of Theodoret have come down to us, partly in a separate collection, partly in the *Acta* of the councils, and partly in the Latin of Marius Mercator; they are of great value not only for the biography of the writer but also for the history of his diocese and of the church in general.

---

[1] Roman Catholic writers vary greatly in their estimate of Theodoret's christology and of his general orthodoxy. On the latest essay on this subject, by Bertram (*Theodoreti, Episcopi Cyrensis, Doctrina Christologica*, Hildesheim, 1883), see *Theol. Lit.-Ztung.*, 1883, 563 *sq.*

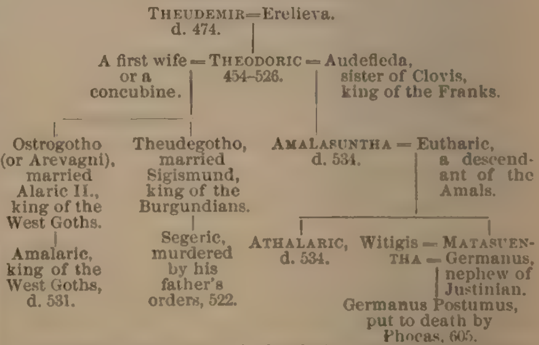
The edition of Sirmond (Paris, 1642) was afterwards completed by Garnier (1684), who has also written dissertations on the author's works. Schulze and Nösselt published a new edition (6 vols., Halle, 1769–74) based on that of their predecessors; a glossary was afterwards added by Bauer. The reprint will be found in vols. lxxx.–lxxxiv. of Migne, and considerable portions occur in Mansi.

Besides the earlier labors of Tillemont, Ceillier, Oudin, Du Pin, and Fabricius and Harless, see Schröckh, *Kirchengesch.*, vol. xviii.; Hefele, *Conc.-gesch.*, vol. ii.; Richter, *De Theodoreto Epp. Paul. Interprete*, Leipsic, 1822; Binder, *Études sur Théodoret*, Geneva, 1844; Stäudlin, *Gesch. u. Lit. der Kirchengesch.*, Hanover, 1827; Kihn, *Die Bedeutung der antioch. Schule*, 1866; Diestel, *Das A. T. in der christl. Kirche*, Jena, 1869; Specht, *Theodor v. Mopsvestia u. Theodoret v. "Theodoret," in Herzog-Plitt's *Realencykl.*, vol. xv. (A. HA.)

THEODORIC, king of the Ostrogoths (*c.* 454–526). Referring to the article GOTHS for a general statement of the position of this, the greatest ruler that the Gothic nation produced, we add here some details of a more personal kind. Theodoric was born about the year 454, and was the son of Theudemir, one of three brothers who reigned over the East Goths, at that time settled in Pannonia. The day of his birth coincided with the arrival of the news of a victory of his uncle Walamir over the sons of Attila. The name of Theodoric's mother was Erelieva, and she is called the concubine of Theudemir. The Byzantine historians generally call him son of Walamir, apparently because the latter was the best known member of the royal fraternity. At the age of seven he was sent as a hostage to the court of Constantinople, and there spent ten years of his life, which doubtless exercised a most important influence on his after career. Shortly after his return to his father (about 471) he secretly, with a *comitatus* of 10,000 men, attacked the king of the Sarmatians, and wrested from him the important city of Singidunum (Belgrade). In 473 Theudemir, now chief king of the Ostrogoths, invaded Mœsia and Macedonia, and obtained a permanent settlement for his people near Thessalonica. Theodoric took the chief part in this expedition, the result of which was to remove the Ostrogoths from the now barbarous Pannonia, and to settle them as "fœderati" in the heart of the empire. About 474 Theudemir died, and for the fourteen following years Theodoric was chiefly engaged in a series of profitless wars, or rather plundering expeditions, partly against the emperor Zeno, but partly against a rival Gothic chieftain, another Theodoric, son of Triarius.[1] In 488 he set out at the head of his people to win Italy from Odoacer. There is no doubt that he had for this enterprise the sanction of the emperor, only too anxious to be rid of so troublesome a guest. But the precise nature of the relation which was to unite the two powers in the event of Theodoric's success was, perhaps purposely, left vague. Theodoric's complete practical independence, combined with a great show of deference for the empire, reminds us somewhat of the relation of the old East India Company to the Mogul dynasty at Delhi, but the Ostrogoth was sometimes actually at war with his imperial friend. The invasion and conquest of Italy occupied more than four years (488–493). Theodoric, who marched round the head of the Venetian Gulf, had to fight a fierce battle with the Gepidæ, probably in the valley of the Save. At the Sontius (Isonzo) he found his passage barred by Odoacer, over whom he gained a complete victory (28th August, 489). A yet more decisive victory followed on the 30th September at Verona. Odoacer fled to Ravenna, and it seemed as if the conquest of Italy was complete. It was delayed, however, for three years by the treachery of Tufa, an officer who had deserted from the service of Odoacer, and of Frederic the Rugian, one of the companions of Theodoric, as well as by the intervention of the Burgundians on behalf of Odoacer. A sally was made from Ravenna by the besieged king, who was defeated in a bloody battle in the Pine Wood. At length (26th February, 493) the long and severe blockade of Ravenna was ended by a capitulation, the terms of which Theodoric disgracefully violated by slaying Odoacer with his own hand (15th March, 493). See ODOACER.

The thirty-three years' reign of Theodoric was a time of unexampled happiness for Italy. Unbroken peace reigned within her borders (with the exception of a trifling raid made by Byzantine corsairs on the coast of Apulia in 508). The venality of the Roman officials and the turbulence of the Gothic nobles were sternly repressed. Marshes were drained, harbors formed, the burden of the taxes lightened, and the state of agriculture so much improved that Italy, from a corn-importing, became a corn-exporting country. Moreover Theodoric, though adhering to the Arian creed of his forefathers, was during the greater part of his reign so conspicuously impartial in religious matters that a legend which afterwards became current represented him as actually putting to death a catholic deacon who had turned Arian in order to win his favor. At the time of the contested papal election between Symmachus and Laurentius (496–502), Theodoric's mediation was welcomed by both contending parties. Unfortunately, at the very close of his reign (524), the emperor Justin's persecution of the Arians led him into a policy of reprisals. He forced Pope John to undertake a mission to Constantinople to plead for toleration, and on his return threw him into prison, where he died. Above all, he sullied his fame by the execution of Boetius and Symmachus (see BOETIUS). It should be observed, however, that the motive for these acts of violence was probably political rather than religious,—jealousy of intrigues with the imperial court rather than zeal on behalf of the Arian confession. Theodoric's death, which is said to have been hastened by remorse for the execution of Symmachus, occurred on 30th August, 526. He was buried in the mausoleum which is still one of the marvels of RAVENNA (*q.v.*), and his grandson Athalaric, a boy of ten years, succeeded him, under the regency of his mother Amalasuntha.

Genealogy of Theodoric.



THEUDEMIR = Erelieva.
d. 474.
A first wife or a concubine.
THEODORIC 454–526.
Audefleda, sister of Clovis, king of the Franks.
Ostrogotho (or Arevagni), married Alaric II., king of the West Goths.
Amalaric, king of the West Goths, d. 531.
Theudegotho, married Sigismund, king of the Burgundians.
Segeric, murdered by his father's orders, 522.
AMALASUNTHA d. 534.
Eutharic, a descendant of the Amals.
ATHALARIC, d. 534.
Witigis
MATASUENTHA
Germanus, nephew of Justinian.
Germanus Postumus, put to death by Phocas, 605.

Amalafrida, a full sister of Theodoric, married Thrasamund, king of the Vandals, and was mother, by an earlier marriage, of Theodahad (d. 536).

Authorities.—The authorities for the life of Theodoric are very imperfect. Jordanes, Procopius, and the curious fragment known as Anonymus Valesii (printed at the end of Ammianus Marcellinus) are the chief direct sources of narrative, but far the most important indirect source is the *Variæ* (state-papers) of Cassiodorus, chief minister of Theodoric. Malchus furnishes some interesting particulars as to his early life, and it is possible to extract a little information from the turgid panegyric of Ennodius. Among German scholars Dahn (*Könige der Germanen*, ii., iii., and iv.), Manso (*Geschichte des Ostgothischen Reichs in Italien*), and Sartorius (*Versuch über die Regierung der Ostgothen*, etc.) have done most to illustrate Theodoric's principles of government. The English reader may consult Gibbon's *Decline and Fall*, chap. xxxix., and Hodgkin's *Italy and her Invaders*, vol. iii., and *Letters of Cassiodorus*. (T. H.)

---

[1] In one of the intervals of friendship with the emperor in 483 Theodoric was made master of the household troops and in 484 consul.

THEODOSIA, or **KAFFA**, a seaport and district town of Russia, situated on the east coast of Crimea, 69 miles to the east-northeast of Simpheropol. Its roadstead, which has a width of 18 miles and is never frozen, is well protected from east and west winds, and partly also from the south, but its depth is small, ranging from 11 to 14 feet and reaching 35 feet only in the middle. The want of railway communication with the interior prevents it from gaining the commercial importance it might otherwise have possessed, so that its population was only 10,800 in 1881,—a low figure when compared with the 20,000 it had in 1672, and still more with the figure returned in last century. Many remains of its former importance exist in the city and neighborhood, the chief being a beautiful mosque—formerly a Genoese cathedral—synagogues several centuries old, old towers with inscriptions, baths, and a palace of Shah-Ghirei in the suburbs. Gardening is one of the leading industries; fishing, a few manufactures, agriculture, and trade are also carried on. The foreign trade, which in 1830–40 reached an average of £90,000 [$437,400] for exports and £66,500 [$323,190] for imports, afterwards fell off, but it has experienced a revival in the course of the last 15 years, the exports of corn, linseed, and wool having reached £167,853 [$815,765.58] in 1884. The imports are insignificant.

Theodosia, a Milesian colony, was in Strabo's day a flourishing seat of trade (especially in grain), with a harbor capable of accommodating a hundred ships; but before Arrian's time (*c.* 125 A.D.) it appears to have been destroyed. More than a thousand years later (1263 to 1267) the Genoese established here their colony Kafa or Kefa, which grew rapidly up notwithstanding the rivalry of the Venetians. It was fortified, and became the see of a bishop, as well as the chief centre for the Genoese colonies on the Black-Sea coasts. It remained nearly independent until 1475, when it was taken by the Turks, but it continued to prosper under their rule, under the name of Kutchuk-Stambul, or Kryon-Stambul (Stambul of Crimea). The Russians took it in 1771, and annexed it in 1774. From that date it began to decay, and had only 3200 inhabitants in 1829, the emigration of the Crimean Tartars and the competition of Odessa being obstacles to its further growth.

THEODOSIUS I., emperor of Rome, surnamed the Great, was the son of Theodosius, Valentinian's great general, who in 368–69 drove back the Picts and Scots from the Roman territories in Britain, and, after other successes on the Continent, was at last despatched to suppress the revolt of Firmus in Mauretania (372). Shortly after (376), the elder Theodosius, despite his great services, was put to death by order of Valens, probably through fear lest he should be the Theodosius or Theodore whom the prophetic tripod indicated as the future emperor.

The younger Theodosius was born about the year 346. He was a native of Spain, but the exact place of his birth is uncertain (Cauca in Galicia according to Idatius and Zosimus, Italica according to Marcellinus). Pacatus and Claudian seem to claim for him at least a relationship to Trajan, of which, however, there is no satisfactory proof. He accompanied his father into Britain (368), and a little later distinguished himself by defeating the Sarmatians who had invaded Mœsia (374). On his father's death he retired to his native place, where he lived quietly till after the great battle of Adrianople (August 9, 378), when Gratian summoned him to share the empire. Theodosius was made Augustus at Sirmium, January 19, 379, and was assigned all the Eastern provinces, including Illyricum. It was a time of great peril for the Roman state. The Huns had just made their appearance on the western shores of the Black Sea, and, after overthrowing the great nation of the Ostrogoths, had driven the more southern Visigoths to take shelter within the empire. Valens had consented to receive them (376) on condition that they should deliver up their arms and surrender their children as hostages to be distributed throughout the cities of the East. The latter half of the compact was enforced, but not the former; and the barbarians, left without any sustenance, began to plunder the open country. After their great victory at Adrianople they reached the walls of Constantinople, whence they were driven back by the valor of a band of Saracens. Meanwhile the Ostrogoths, the Taifali, the Huns, and the Alans had all crossed the Danube to share the spoils of the empire; and it was against this motley host that Theodosius had to contend. He appears to have gained some successes even before his elevation to the empire (Theodoret, v. 5, 6), and shortly after this retired to Thessalonica to organize his forces. He breathed courage into what remained of the Roman army, and summoned the very miners to his standard. But his chief reliance was placed in certain bodies of the Goths whom he had enrolled in his service. These, under their royal leader Modares, gained at least one decisive victory, probably in the course of 379. From the unchronological account of a later writer, Zosimus, to whom we owe almost all the details of Theodosius's early campaigns, we may infer that in the course of this year or the next Fritigern and his Visigoths were gradually driven across the Danube, where they seem to have met with the Ostrogoths who had shared their fate. For a time the united nations turned their energy against the Western empire, till they forced Gratian to grant them leave to settle in Pannonia and Mœsia. Before setting out on their new journey they perhaps combined their forces to attack Athanaric, who had retreated with his section of the Visigoths into the wilds beyond the Danube at the time of the Hunnish invasion. Unable to withstand their onset, Athanaric offered his services to Theodosius, and was received into Constantinople with every mark of favor, 11th January, 381. Fifteen days later he died, and was honored by the emperor with a splendid funeral, while his followers faithfully discharged the duty of guarding the Danube.

In the two preceding years Thessaly and Macedonia had been swept by the barbarians. On one occasion the emperor himself barely escaped from their hands in a midnight attack which they had been induced to make by the sight of his blazing watchfires; on another the united forces of the Ostrogoths and Visigoths crossed the Danube with the design of pillaging Greece. In his efforts against the invaders Theodosius was ably seconded by his colleague Gratian, who despatched his Frankish officers Baudo and Arbogastes to drive the enemy out of Macedonia and Thessaly (380), and, while Theodosius lay sick at Thessalonica, made such terms with them as the latter emperor was glad to accept on his recovery. A little later, presumably towards the middle of 381, Promotus, Theodosius's lieutenant, inflicted a terrible defeat on a motley host that was attempting to cross the Danube. This was perhaps the decisive battle in the war; and we read that on October 3, 382, all the remaining Goths in the empire submitted to Theodosius. Many of them appear to have entered the Roman army as "fœderati"; and indeed, from the very commencement of his reign, Theodosius seems to have pursued a consistent policy of enrolling the Gothic warriors. At times they accepted his gifts while meditating treachery in their hearts; and Eunapius has preserved the story of how Fravitta, the leader of the faithful party, slew with his own hands his dishonest colleague Eriulf at a banquet in the emperor's own tent. Zosimus has charged Theodosius with burdening the provinces with excessive duties for the purpose of maintaining a host of useless barbarian officers, while the common soldiers were left unpaid. These barbarian troops, according to the same writer, often treated the Roman citizens with the utmost indignity, and on more than one occasion provoked a retaliation for which the emperor refused to see any excuse. They were not, however, all quartered in one place, but received into the legions; while others were sent to Egypt. On the whole, it may be said that his policy of attaching the invaders to himself was the salvation of the empire; it was they who bore the brunt of the battle of the Frigidus; and the knowledge of the emperor's good faith towards the Teutonic auxiliaries in his service must have contributed largely to the defection of Eugenius's army on the same occasion.

In 383 Theodosius created his eldest son Arcadius Augustus. The same year saw the revolt of Maximus in Britain and the murder of Gratian (August 25, 383). For five years Theodosius consented to accept the usurper as his colleague; but, when Maximus, flushed with success, attempted a few years later to make himself master of Italy, which, since the sudden death of Valentinian I. (17th November, 375), had been governed under the name of his young son Valentinian II., Theodosius advanced against the invader and overthrew him near Aquileia (28th July, 388). This victory was followed by the murder of Maximus and his son Victor, after whose death Theodosius conferred upon Valentinian II. all that part of the empire which his father had held. Theodosius is said to have been induced to take this campaign by his love for Valentinian's sister Galla, whom he now married. Meanwhile there had been fresh dangers from the Goths. In 386 another band of the Grœthingi or Ostrogoths, attempting to cross the Danube, was cut off by Promotus. The same general, in the course of the next two years, punished the barbarians who had deserted Theodosius at the beginning of the campaign against Maximus. Such signal services as these, though coupled with the fact that he had saved the emperor's life, did not prevent Promotus from falling a victim to the intrigues of the favorite Rufinus, who is charged by Zosimus with compassing the death of other noble men. If we may trust the evidence of the last-mentioned historian, from the end of the year 388 Theodosius resigned himself to gluttony and voluptuous living, from which he was only roused by the news that, in the Western empire, Arbogastes the Frank had slain the young emperor Valentinian and set up the grammarian Eugenius in his stead (15th May, 392).

Into the curious history of the short-lived pagan revival in the Western empire there is no need to enter here. Zosimus assures us that the tears of Galla threw the whole court into confusion; but there can be little doubt that to a religious, if not superstitious, mind like that of Theodosius it might well have seemed that he was fighting the battles of God, as he led his army of the cross against an enemy on whose standard shone the image of Hercules (Theodoret, v. 24). His host consisted partly of Romans and partly of barbarians. Timasius was leader of the former, but under him was ranged the more renowned Stilicho; the latter were led by Gainas the Goth and Saul the Alan. The engagement was fought near the river Frigidus, some thirty-six miles distant from Aquileia. On the first day Theodosius's barbarians, engaging with those of the hostile army, were almost destroyed, and the victory seemed to be with Eugenius. After a night of prayer, towards cock-crow the emperor was cheered by a vision of St. Philip and St. John, who, mounted on white steeds, promised him success. With the morning he received and accepted the offer of service on behalf of the enemy's ambush, and once more advanced to the conflict. But even so, the issue of the day was doubtful till, if we may trust the concurrent testimony of all the great contemporary church historians, a sudden gust of wind blew back the enemy's arrows on themselves. This was the turning-point of the battle: Eugenius was slain by the soldiers; and two days later Arbogastes committed suicide (September 5–9, 394). From the northeastern parts of Italy Theodosius passed to Rome, where he had his son Honorius proclaimed emperor under the guardianship of Stilicho. Thence he retired to Milan, where he died of dropsy (17th January, 395), leaving the empire to be divided between his two sons Honorius and Arcadius,—Honorius becoming emperor of Rome and the West, Arcadius of Constantinople and the East.

Important, however, as the reign of Theodosius was from the political point of view, it is perhaps still more important from the theological. According to Sozomen, his parents were both orthodox Christians, according to the creed sanctioned by the council of Nicæa. It was not, however, till his illness at Thessalonica that the emperor received baptism at the hands of Bishop Ascholius, whereupon, says the same historian, he issued a decree (February, 380) in favor of the faith of St. Peter and Pope Damasus of Rome. This was to be the true catholic faith; the adherents of other creeds were to be reckoned as heretics and punished. The great council of Constantinople, consisting of 150 orthodox and 36 Macedonian bishops, met in the following year, confirmed the Nicene faith, ordered the affairs of the various sees, and declared the bishop of Constantinople to rank next to the bishop of Rome. The emperor cannot be acquitted of the intolerance which marks edicts such as that depriving apostatizing Christians of the right of bequest. It was not till 389 or 390 that he issued orders for the destruction of the great idol of Serapis at Alexandria. Other edicts of an earlier or later date forbade the unorthodox to hold assemblies in the towns, enjoined the surrender of all churches to the catholic bishops, and overthrew the heathen temples "throughout the whole world." During the reign of Theodosius, Gregory of Nazianzus was made bishop of Constantinople—an appointment which he did not long retain. In 383 Theodosius called a new council for the discussion of the true faith. The orthodox, the Arians, the Eunomians, and the Macedonians all sent champions to maintain their special tenets before the emperor, who finally decided in favor of the orthodox party. He seems to have suffered the Novatians to hold assemblies in the city. Perhaps the most remarkable incident in the life of Theodosius from a personal point of view is the incident of his submission to the reprimands of Ambrose, who dared to rebuke him and refuse to admit him to the Lord's Supper till he had done public penance for suffering his Gothic auxiliaries to murder the townsmen of Thessalonica (390). Equally praiseworthy is the generous pardon that the emperor, after much intercession, granted to the seditious people of Antioch, who, out of anger at the growing imposts, had beaten down the imperial statues of their city (387). When the Christians in the eastern part of the empire destroyed a Jewish synagogue and a church belonging to the Valentinians, Theodosius gave orders for the offenders to make reparation. Such impartial conduct drew forth a remonstrance from Ambrose, who, where the interests of his creed were concerned, could forget the common principles of justice. In a sermon preached before Theodosius he introduced the Deity Himself holding an argument against Theodosius on the subject of his remissness, and the imperial penitent yielded to the eloquent bishop. So pliant a disposition rendered him very dear to the saint, who availed himself of his influence to counteract the efforts of Symmachus and the Roman senate for the restoration of the pagan rites at the altar of victory. "I loved the man," says St. Ambrose, "who, putting off his kingly robes, mourned publicly in the church a sin to which the guile of others had exposed him,—an emperor who thought it no shame to do an act of public penance that even private people would have blushed to perform." The inspired vision of the saint saw the deceased emperor received into heaven by his old colleague Gratian; while Maximus and Eugenius down in hell were already experiencing how grievous a sin it is to take up arms against lawful princes (Ambrose, *De Obitu Theod.*).

Theodosius was twice married—(1) to Ælia Flacilla, the mother of Arcadius (377–408) and Honorius (384–423); (2) to Galla (d. 394), the daughter of Valentinian I.

The chief authorities for the age of Theodosius are Ammianus Marcellinus, Zosimus, Eunapius, and the ecclesiastical historians (Socrates, Sozomen, Theodoret). Much information may also be gleaned from the writings of St. Ambrose, St. Gregory of Nazianzus, Isidore of Seville, and the orators Pacatus, Libanius, Themistius. Of modern authorities Tillemont supplies an unrivalled collection of facts drily collected from all contemporary or nearly contemporary sources; he is specially useful for his synopses of the Theodosian laws. Clinton's *Fasti* are the best guide for the chronology of the period. It is hardly necessary to mention the brilliant account given by Gibbon, or, in later years, from the standpoint of Italian history by Mr. Hodgkin. (T. A. A.)

THEODOSIUS II. (401–450) succeeded his father Arcadius as emperor of the East in 408. During his minority the empire was ruled by the prætorian prefect Anthemius and Pulcheria, who became her brother's guardian in 414. Under his sister's care the young emperor was brought up rather as a virtuoso than a prince. The chief events of Theodosius's reign are the wars with Persia in 421 and 441, the council of Ephesus (431), and the invasion of the Huns under Attila (441–448). In 450 Theodosius was thrown from his horse while hunting, and received injuries from which he died. He married Athenais, who on being baptized took the name of Eudocia. It was during his reign that the *Codex Theodosianus*, or collection of the constitutions of the Roman emperors, was formed. The idea took birth as early as 425, but was only put into execution between 435 and 438; in the latter year the Code was published.

THEODOSIUS III. was the last of three emperors whose short reigns filled the interval between the death of Justinian II. and the accession of Leo the Isaurian. The emperor Anastasius had sent a fleet to frustrate the intended expedition of the Saracens from Alexandria against Constantinople. On reaching Rhodes the troops rose against their leader, John the Deacon, slew him, and, starting for Constantinople, landed at Adramyttium, where they made a collector of the taxes emperor by the title of Theodosius III. The new emperor besieged Constantinople for six months before he took it; Anastasius resigned, and retired to a monastery, leaving his place to be filled by Theodosius III., who likewise resigned next year (717) in favor of Leo III. The closing years of Theodosius's life were spent in a monastery.

THEODOSIUS, of Tripolis, a Greek geometer and astronomer, three of whose works were contained in the collection of lesser writings named 'Ο *μικρὸς ἀστρονομούμενος* (sc. *τόπος*), or 'Ο *μικρὸς ἀστρόνομος*.[1] Pappus of Alexandria, at the commencement of the sixth book of his *Συναγωγή*, speaks of this collection, the study of which is indispensable to any one who would master the science of astronomy (*τὸν ἀστρονομούμενον τόπον*). These writings, which were highly esteemed in the school of Alexandria, were intermediate between the *Elements* of Euclid and the *Almagest* of Ptolemy, for the understanding of which, indeed, they formed an indispensable introduction. Of the life of Theodosius nothing is known. As to the time when he lived different opinions have been held, he being placed by some in the first century before and by others in the second century after the Christian era. The latter opinion is founded on an error of Suidas (*s.v.*), who on the one hand identifies the author of the three works referred to above with a skeptical philosopher of the same name who lived at the time of Trajan or later, and on the other hand distinguishes him from a native of Tripolis who wrote a poem on spring. It is now generally admitted that the subject of this article is the same as Theodosius the mathematician, who is mentioned by Strabo amongst the natives of Bithynia distinguished for their learning, and whose sons were also mathematicians, the same, too, as the inventor of a universal sun-dial (*horologium πρὸς πᾶν κλίμα*) of that name who is praised by Vitruvius (*De Architectura*, ix. 9). His date, therefore, could not have been later than the 1st century B.C.; he may, however, have lived in the preceding century, inasmuch as the names mentioned by Strabo in the passage referred to above are, as far as we know, arranged chronologically, and Theodosius immediately follows Hipparchus, who made astronomical observations between 161 and 126 B.C., and precedes Asclepiades the physician, who lived at Rome at the beginning of the 1st century B.C.

The statement that he was "of Tripolis" is made, not on the authority of Suidas, as has been erroneously said, but because he is so described in the title of his principal work. It is probable, therefore, that he was a native of Bithynia, and resided at Tripolis, where he wrote his work. Tripolis is generally taken to be the city of that name on the Phœnician coast, but it may have been a town of the same name in Lydia, on the Meander.

His chief work—*Σφαιρικά*, in three books—treats of the properties of the sphere and its sections, with the object of establishing the geometrical principles of spherical astronomy. This work, which is classical, is distinguished for the order and clearness of the exposition as well as for the rigor of its proofs, and has ever since formed the basis on which the subject of spherical geometry has been treated. It does not contain any trace of spherical trigonometry, which, on the other hand, was the special subject of the work having the same title, and included in the same collection, of Menelaus of Alexandria, who lived at the end of the 1st century.

Montucla suspected that a great part of the three books of Theodosius must have been known before his time, and that he merely did with respect to this branch of geometry what Euclid had done with the elements, namely, he collected and incorporated in his work the different propositions found before his time by astronomers and geometers. This conjecture of Montucla has been confirmed by A. Nokk (*Ueber die Sphärik des Theodosius*, Karlsruhe, 1847), by Heiberg (*Litterargeschichtliche Studien über Euklid*, pp. 43 *sq.*, Leipsic, 1882), and by Hultsch, from whose researches, and especially owing to the publication by the last of the *editio princeps* of Autolycus, it is now quite certain that as early as the middle of the 4th century B.C. there existed a Greek text-book on *Spherics* which, in its essential contents, scarcely deviated from the three books of Theodosius. He must therefore be regarded as merely the editor, or at most the elaborator and expounder, of a doctrine which existed some centuries before him.

The *Spherics* of Theodosius was translated into Arabic at the beginning of the 10th century, and from the Arabic into Latin in the 12th century by Plato of Tivoli (Tiburtinus). This translation was published in 1518 at Venice, but was found so faulty by J. Voegelinus that he published a new Latin version, together with additions from the Arabian commentators, Vienna, 1529, 4to; other Latin translations were published by F. Maurolycus, Messina, 1558, fol.; by C. Clavius, Rome, 1586, 4to; and by Barrow under the title, Theodosii *Sphærica, Methodo Nova Illustrata et Succincte Demonstrata*, London, 1675, 4to. The Greek text was first published, and with it a Latin translation, by J. Pena, Paris, 1558, 4to; it has been edited since by Joseph Hunt, Oxford, 1707, and by E. Nizze, Berlin, 1852, but these two editions are founded on that of Pena. There is also a German translation by Nizze, Stralsund, 1826. His two editions are accompanied with valuable notes and an appendix containing additions from Voegelinus and others.

The two other works of Theodosius which have come down to us have not as yet been published in the original. The propositions, without demonstrations, in the work *περὶ ἡμερῶν καὶ νυκτῶν* (*On Days and Nights*), in two books, were given by Dasypodius, in Greek and Latin, in his *Sphæricæ Doctrinæ Propositiones*, Strasburg, 1572, 8vo. A Latin version of the complete work, with ancient *scholia* and figures, was given by Joseph Auria, Rome, 1591, 4to. Pappus has given a pretty full commentary on the first book of this work of Theodosius. His work *περὶ οἰκήσεων* (*On Habitations*) also was published by Auria, Rome, 1588. It gives an account of how, for every inhabitant of the earth from the equator to the pole, the starry firmament presents itself in the course of a year. The propositions in it were also given by Dasypodius in his work mentioned above.

THEOGNIS OF MEGARA was one of the early Greek elegiac poets; he probably flourished about the middle of the 6th century B.C. We derive our knowledge of his life from the poems that bear his name. After the fall of Theagenes, who had made himself tyrant of Megara about 625, the usual struggles between oligarchy and democracy ensued. Theognis was a violent partisan of the oligarchical faction in his native town, and wrote elegies in which he gave expression to the emotions roused in him by the varying phases of the struggle. He appears on one occasion to have lost his property (verse 345) and been driven into exile: perhaps it was then that he visited Sicily, Eubœa, and Sparta (783 *sq.*). In the end—if we may trust 1123 *sq.*—he returned to Megara, and lived, at least for a time, in something like prosperity. The date of his death is unknown. The verses handed down to us under the name of Theognis amount in all to 1389. Not a few of them are ascribed on the evidence of the ancients to Tyrtæus, Mimnermus, and Solon; modern criticism has made it probable that two of the longer elegies are from the hand of Evenus (467–496 and 667–686); other fragments are demonstrably later than Theognis. It is now generally admitted that the *Theognidea* were put together long after Theognis—possibly even as late as the 4th century B.C.—by some compiler who wished to provide a good collection of moral maxims for educational purposes. To separate the genuine fragments of Theognis from those which were ascribed to him by the reverence of a later age is a hopeless task.

---

[1] This collection contained the following books: "Theodosii Tripolitæ *Sphæricorum* libri iii.; Euclidis *Data, Optica, Catoptrica, ac Phænomena*; Theodosii Tripolitæ *De Habitationibus* et *Noctibus ac Diebus* libri ii.; Autolyci Pitanæi *De Sphæra Mota*, et libri ii. *De Ortu atque Occasu Stellarum Inerrantium*; Aristarchi Samii *De Magnitudinibus ac Distantiis Solis ac Lunæ*; Hypsiclis Alexandrini 'Αναφορικὸς sive *De Ascensionibus*; Menelai *Sphæricorum* libri iii."—Fabricius, *Bibliotheca Græca*, ed. Harles, iv. p. 16.

The collection is divided into two books. The first, which is addressed to a youth called Cyrnus, or Polypædes, opens with a spirited invocation of Apollo and Artemis, along with the Muses and the Graces (vv. 1–18); then follows a passage which has been much discussed in connection with the early history of writing, recommending Cyrnus to set a seal upon the author's verses, to prevent forgers from passing off spurious lines under his name (see Jevons, *Hist. of Greek Lit.*, p. 46). With verse 27 begins a series of counsels to Cyrnus. On the whole they are remarkable neither for loftiness of tone nor for poetic elevation. Cyrnus is counselled to avoid "the bad" and frequent the society of "the good" men—the terms "good" and "bad" being used to denote aristocrats and democrats, just as *καλὸς κἀγαθὸς* meant an oligarch in the later days of the Peloponnesian War. Sometimes the violence of party feeling leads Theognis beyond all bounds, as when he prays that he may "drink the black blood" of his opponents (349; *cf.* 337 339 and 361). One striking feature in these elegies is the continual refrain about the evils of poverty. "To avoid poverty one should even throw oneself into the vasty deep, or from the beetling rocks" (175–176; *cf.* 266 *sq.*, 351 *sq.*, and 649 *sq.*). Elsewhere the poet reproaches Zeus with allowing evil men to prosper, and afflicting the good (373 *sq.*); he also complains that the punishment due to wicked men often falls upon their sons (731 *sq.*). A pleasing feature is the high value which is placed upon friendship; one is not to part with a friend lightly or upon some slight occasion of displeasure (323 *sq.*). At the same time no one knows better than Theognis how quickly friends fail one in adversity (299–300). Life has on the whole few charms for our poet: "the best thing for man is not to be born or look upon the rays of the swift sun; once born it is best for him to pass as soon as possible the gates of death, and lie with a great barrow of earth above him." (425–429). The prevailingly sad tone of the elegies is occasionally broken by a convivial note. "It is shameful," says the poet, "to be drunk when others are sober, or sober when others are drunk" (626–627); "among the uproarious I am very uproarious, but among the proper I am the properest of men" (313–314). The only elegy which possesses any considerable poetic merit in the first book is that in which Theognis predicts immortality for his young friend through the fame awaiting his own poems. The second book (1231–1389) consists of a number of amatory elegies addressed to some young friend of the author's. In vigor and harmony of versification they are on the whole superior to the first book; but most if not all of them are probably spurious.

Bergk, *Poetæ Lyrici Græci*, ii. 117–236, Leipsic, 1882.

THEOLOGY.

The word theology in the classics;

THE word theology comes from a heathen source—from the Greek classics. In the *Republic* of Plato and the *Metaphysics* of Aristotle it occurs, and in its etymological meaning of "discourse or doctrine concerning Deity and Divine things"—*λόγος περὶ τοῦ θεοῦ καὶ περὶ τῶν θειῶν.* Men who wrote about the gods and their doings, or who speculated about the Divine in the origination and operations of nature—men like Homer, Hesiod, Pherecydes, and Thales,—were called *θεολόγοι.* But there could, of course, be no theological science based on the popular religion of Greece. Theology was only to be found among the Greeks in the form of philosophical speculation. Through St. Augustine we know that Varro, "the most learned of the Romans," distinguished three kinds of theology,—the first mythical or fabulous, the second physical or natural, and the third civil or popular. The mythical theology he censured as containing many things contrary to the dignity and nature of immortal beings; the natural theology he described as that which is true but beyond the capacity of the vulgar; the civil theology he considered to be that which it was good for the citizens to believe—the received religion of Rome. The general attitude of the Greek and Roman mind to religion was unfavorable to the cultivation of theology. Religion being dissociated in thought from truth could not give rise to science.

in the fathers;

The words theology and theologian do not occur in Scripture, but it was inevitable that they should be transplanted into Christian soil. Θεόλογος is found, as a V.R. in the inscription of the Apocalypse—the Revelation of John "the Divine," "the theologian,"—and almost certainly refers to his maintaining the Divinity of the Logos—*τὴν τοῦ λόγου θεότητα,*—that the *λόγος* is *θεός.* In the 3d and 4th centuries a theologian usually meant one who distinguished himself in defending the personality and Divinity of the Logos. It was on this ground that Athanasius and Gregory Nazianzen were honored with the distinctive appellation of "theologians." The term theology has not yet lost its early signification of "doctrine concerning God," although a much wider meaning is more common. Theology in its ordinary general acceptation includes, as one of its divisions, theology understood as the treatment of the problems which directly refer to the being, attributes, and works of God. *The Introductio ad Theologiam*, and a later form of it, the *Theologia Christiana*, composed by Abelard in the 12th century, first gave currency to an acceptation of the word inclusive of all religious truth or belief. Among later scholastics the common designation for a general compendium of religious doctrine was *Summa Theologiæ.* Of such *Summæ* among the most celebrated and characteristic are those of Alexander Hales, Albertus Magnus, and Thomas Aquinas. The mediæval mystics deemed the essence of theology to be the immediate intuition of God, who, being once in contact with the soul, reveals to it the truth of all the principles of faith, and gives it at the same time spiritual peace and happiness. This view led to a use of the word which was prevalent among the Reformers and their immediate successors,—a subjective application which identified it with what was characteristic of the mind of a true theologian, an enlightened and experienced *homo renatus.* In this sense it was a living practical acquaintance with the revelation of grace and truth made by God to man, a "habitus practicus," a "sapientia eminens practica," as it was called. With it, however, these earlier Protestant divines generally conjoined that objective application of the term which was current in later scholasticism, and this at length wholly displaced the subjective acceptation; in other words, theology came to signify, not knowledge of a certain kind as inherent in the mind and operative in the life of the individual, but knowledge in itself, a body of systematized truth, a science. Theology, thus understood, may be viewed, discussed, and applied in a variety of ways, so as to give rise to certain kinds or species of theology. In the 17th century the necessity for specialization of this sort began, from the operation of several causes, to be widely and strongly felt, and it became usual for divines to indicate by the titles of their theological

in the Middle Ages;

at and after the Reformation.

systems the point of view and mode of treatment adopted. An adjective added to the term "theologia" served their purpose. Of adjectives thus employed in the 17th and early part of the 18th century, the following may be mentioned as either frequently used or of some intrinsic interest: theoretica, practica, didactica, elenctica, polemica, irenica, pacifica, positiva, comparativa, dogmatica, theoretico-practica, didactico-elenctica, etc.

Natural theology.

Comparative theology.

The extension given to the signification of the term theology was for a very lengthened period almost universally restricted to the knowledge derivable from the Scriptures, the systematic exhibition of revealed truth, the science of Christian faith and life. It is still thus, perhaps, that the word is most commonly understood. Two things, however, have naturally suggested the employment of it in a wider manner. First, there was the rise and development of a theology not based on revelation,—the rise and development of what is called natural theology. The Greeks and Romans could not distinguish between nature and revelation, reason and faith, because ignorant of revelation and faith in their distinctive Christian sense. In the patristic and scholastic ages of the church, and for some time after the Reformation, men were not in general prepared to admit that there was a knowledge of God and of His attributes and of his relations to the world which might be the object of a science distinct from and independent of revelation. Yet the most learned and thoughtful even of the scholastic divines recognized in some measure that such was the case, and could hardly, indeed, do otherwise after they had become acquainted with the contributions which Greek, Jewish, and Arabian philosophers had made to the defence and elaboration of the doctrine concerning God. The separation of natural and revealed theology was virtually the work of the scholastics. The *Theologia Naturalis sive Liber Creaturarum* of the Spanish physician, Raymond de Sebonde, who taught theology in the university of Toulouse during the earlier part of the 15th century, was, perhaps, the first work which, proceeding on the principle that God has given us two books, the book of nature and the book of Scripture, confined itself to the interpretation of the former, merely indicating the mutual relations of natural and revealed religion. A conviction of the truth of the distinction which he so clearly apprehended gradually spread; more and more importance came to be attached to it. The deists proceeded on it, and tried to exalt natural theology at the expense of all theology professedly based on revelation, by representing the former as the truth of which the latter was the perversion. The wisest of their opponents, and thoughtful Christian writers in general—the adherents of the moderate and rational theology of the 17th and 18th centuries—strove, on the other hand, to show that natural theology was presupposed by revelation and should carry the mind onwards to the acceptance of revelation. Thus natural theology came into reputation, notwithstanding the opposition of those who have denied its existence and contended that the reason of itself can teach us absolutely nothing about God or our duties towards Him. The recognition of natural theology contributed to awaken an interest in the various religions of the world, and thus led to the second circumstance referred to, namely, the rise of what may be called comparative theology, although it has hitherto been more generally designated the science of religions. It can be shown to have originated in the attempts made to prove that the principles of natural theology were to be found in all religions. In Bishop Steuco of Kisami's *De Perenni Philosophia*, published in 1540, and in Lord Herbert of Cherbury's *De Religione Gentilium*, published in 1663, we have two of the earliest and most characteristic attempts of the kind. From that time to the present the study of religions has proceeded at varying rates of progress, but without interruption. Important results have been obtained, and especially this result, the ascertainment, to the satisfaction of all competent judges, of a right method of investigation,—the establishment, as the true mode of study, of the comparative method. As we have a right to speak of comparative anatomy and comparative philology, so have we a right to speak of comparative theology. The inference from the preceding remarks is obvious. If there be a natural theology and a comparative theology, it is a mistake to identify theology *per se* with Christian theology. The word Christian is, in this case, a real and great restriction of the signification of the word theology, and Christian theology is not the only kind of theology. The proper procedure is to give to theology a general and comprehensive meaning, which can be limited and specialized, when requisite, by adjectives like "natural" or "Christian."

Is theology the science of religion or the doctrine of God?

What, then, is the general signification which we should give to the term? There is room for difference of opinion, and especially as to whether God or religion should be regarded as the object of the science. Is theology the science which treats of God? or is it the science which treats of religion? The latter view is now, perhaps, the more current. In addition to intrinsic reason, the critical and skeptical spirit of the time is in its favor. Many speak of theology as a science of religion because they disbelieve that there is any knowledge of God to be attained. Dr. Martineau, in his lecture on *Ideal Substitutes for God*, protests against this tendency, and contends that the older view of theology, as the doctrine or rational apprehension of *God*, ought not to be abandoned, seeing that the new "science of religions," *i.e.*, "the systematic knowledge of what *men have believed and felt* on things sacred to them," can be no proper substitute for the old "theology." We may admit, however, that the protest is essentially true,—that a knowledge of man's religious opinions, emotions, and actions can never supply the place of a knowledge of God, that, when from religion its objective basis, the reality and apprehensibility of God, is taken away, the study of it can have merely the psychological interest which belongs to mental disease and illusions,—and yet prefer the definition of theology as "the science of religion" to its definition as "the doctrine of God." The latter seems much too narrow. Even Christian dogmatics is about as much occupied with man as with God. The doctrines of sin and of the church, for example, are not doctrines regarding God. Then, although the new "science of religions" is not a substitute for the old "theology," it is still a science or at least a very interesting and important branch of knowledge, which yet cannot be brought under the definition of theology approved by Dr. Martineau,—the definition immediately yielded by the etymology of the term. The science of religion is a very different thing from the "science of religions." It is far more comprehensive. The "science of religions" is but one of the latest offshoots of the science of religion; the old theology is its main trunk or stem. Theology, when viewed as the science of religion, has not to do merely with the religious consciousness and its states. It must aim at the complete comprehension of religion and, unless religion be a delusion and disease, this can never be attained by treating religion merely as a subjective or psychological process to which there are no corresponding objective realities manifested either through nature or revelation. We have no right to assume that it is thus without a real and rational foundation in fact; on the contrary, we are bound to inquire whether it has external grounds and real objects or not, and, if it have them, what they are. We must endeavor to ascertain and expound its objective grounds as well as its subjective contents.

Thus the definition of theology as the science of religion in no way excludes what is implied in the definition of it as the science conversant about God and Divine things. It includes more than the latter definition, but does not exclude anything contained therein.

Objections to the former definition met.

The definition of theology as the science of religion has been objected to by Dr. Charles Hodge on two grounds:[1] first, that the word religion is ambiguous, having both an objective sense and a subjective sense, and that its etymology is doubtful; and, second, that to define theology as the science of religion "makes theology entirely independent of the Bible. For, as moral philosophy is the analysis of our moral nature and the conclusions to which that analysis leads, so theology becomes the analysis of our religious consciousness together with the truths which that analysis evolves." As to the first objection, the word religion has, it is true, more significations than one, and consequently may be ambiguously used, but in point of fact it is not so used in the definition in question, in which religion is understood in its generic meaning, and as inclusive both of subjective and of objective religion. Theology has to treat of both, and if it treat of them aright it will not confound them. "The etymology of the word religion is doubtful." Very true. But is no word to be employed in a definition if its etymology be doubtful? That would be an extremely hard law. In definition we have only to do with the actual meaning of terms; we have nothing to do with their origin or history. As to the second objection, it has to be remarked that the definition does not make theology entirely independent of the Bible. It does not make Biblical theology in any degree independent of the Bible. It does not imply that the Bible is not the sole perfect standard by which truth and error, health and disease, are to be separated in the religious consciousness of individuals and the religious history of the race. It only implies that all religious phenomena whatever are to be studied by the theologian, just as moral philosophy cannot leave any moral phenomena unstudied. Moral philosophy, in treating of vice as well as of virtue, does not thereby equalize vice and virtue; and no more does comparative theology, when it treats both of Christianity and heathendom, assume that the former has no superiority over the latter. It is merely a part of the task of moral philosophy to analyze the moral consciousness; it is an equally essential part thereof to inquire into the foundation of rectitude, and to determine objective moral distinctions and relations. In like manner theology has much more to do than merely to analyze the religious consciousness; it has also to treat of the grounds and objects of religion. If some reduce it to a mere analysis of the religious consciousness, and overlook or deny that there is an objective religious revelation in nature and Scripture as well as a religious susceptibility in the mind of man, this is no logical consequence of the statement that theology is the science of religion. There needs, perhaps, no other proof that the definition to which Dr. Hodge objects is of some use than to consider for a moment his own definition. "Theology is the science concerned with the facts and the principles of the Bible." Is theology, then, not concerned with the facts and principles of the physical world, the human mind, and history, so far as these are disclosures of God's nature and ways? How can theology start from the Bible when it needs to be proved that there is a revelation from God in the Bible? And how can this be proved unless it is known from other sources than the Bible that there is a God? If there be such sources, theology must have to do with them; it can have no right to neglect anything by which God may be known or by which light may be thrown on the relations between God and man. It is a service to theology so to define it as to leave no room for asserting that it is only conversant with the Bible.

Relation of theology to religion.

Theology, then, is the science of religion. What does this definition imply as to the relation of theology to religion? It implies, first, that theology presupposes and is preceded by religion. This is but an instance of the general truth that experience must precede science, and that science must be founded on experience. The implicit use of principles is always prior to their explicit development. Speech is a great deal older than grammar; men reasoned long before Aristotle taught them how they reasoned; and just as there must be speech before grammar, and reasoning before logic, so must there be religion before theology. Secondly, that theology is the science of religion implies that theology must not only succeed religion, but must evolve out of it a system of truth entitled to be called a science. Science is knowledge in its completest, highest, and purest form. Theology, therefore, by claiming to be the science of religion, professes to be the exhibition of religious facts and principles in their most general and precise shape, in their internal relationship to one another, in their organic unity and systematic independence. The principles of causality and of unity in the human mind impel it to seek law and order, explanation and connection, as regards the phenomena of religion no less than any other species of phenomena; they impel it, in other words, to perfect its knowledge of these phenomena, and can allow it no rest until it has attained to the system and science of them. Theology is the scientific system of them, and as such is a necessity to the thoughtful religious mind. It is no accident that in every age and nation thoughtful men have reflected on their religious convictions, and sought to trace them to their grounds, and to harmonize and systematize them, or that the Christian church has anxiously studied and debated for centuries problems concerning God, Christ, sin, salvation, etc.,—no accident but the necessary consequence of those fixed laws of human nature by which man ever seeks, once that his intellect has been truly awakened, to define and complete his knowledge. Conscious that his religious experience, however vivid, involves much which requires to be cleared up; perceiving that the religious history of his race presents many apparently contradictory facts, many perplexing problems; aware that the Bible is no more a system of theology than nature is a system of mechanics or chemistry,—man cannot, as a rational being, do otherwise than endeavor by the investigation of the whole phenomena of the case to verify, analyze, combine, and co-ordinate his notions as to spiritual things, so as to work them up into a comprehensive, consistent, firmly established, adequately certified, naturally organized whole, a scientific system.

But how may man hope to succeed in his efforts to arrive at a scientific understanding of his religious beliefs, feelings, and practices? How may he educe and elaborate from the phenomena of religion a system of theology entitled to be called science? Only, it is obvious, by following a truly scientific method. What then is a truly scientific method in theology? And what is implied in following it? To these questions a comprehensive, although necessarily brief, answer must now be given.

Scientific method in theology.

A right method in theology, as in all other sciences, is such a use of reason on appropriate facts as will best attain truth. It implies, therefore, as an essential condition, a right relation of reason to religious truth or fact, and to the evidence for it. What the right relation is may, perhaps, be defined with substantial accuracy in the following propositions. (1) Religious truth, like all other truth, is "above reason" in the sense of being not created by but manifested to reason, but is not "above reason" in any special sense which withdraws it from the cognizance of reason.

---

[1] *Systematic Theology*, vol. i. pp. 20-21.

Religious truth not above reason.

The truths of all science are the discoveries but not the creations of science, and they have been discovered because they existed, because they are the equivalents of a reality which is independent of science. In regard alike to mathematical, physical, mental, and religious truth, reason has only power to seek it, and to find or to miss it; it has no power to make it or right over it, but must accept it as something presented or given to it, and to which it is bound to do homage and yield submission. In this sense all truth is above reason, and revealed to reason. In this sense reason stands to religious truth in the same relation as to physical truth, and to Christian truth in the same relation as to the truth in natural religion. Reason is simply the instrument or faculty of apprehending the truth manifested or revealed to it, and it can in no case apprehend truth without the aid of the appropriate manifestation or revelation. Unless Christ had lived and taught, reason could never have known His character and doctrine; but no more could it have known Dante and his *Divina Commedia*, Shakespeare and his creations, Napoleon and his achievements, unless these men had appeared in the world and accomplished in it their work. Without Christ the truth in Christ could not be known, but, Christ being given, that truth comes under the cognizance of reason, ceases to be in any special sense above reason and affords to reason material for science. By truths above reason are sometimes meant truths which cannot be fully apprehended by reason. Such truths, are, however, in no way peculiar to religion. In all regions and directions reason finds that its range of vision is limited, and that its knowledge and science are bounded by nescience and mystery. Truths of special revelation are sometimes represented as above reason in the sense that reason can have no other evidence for them than that of testimony and external authority. But what truths of Scripture have thus been revealed to reveal nothing, and are thus devoid of intrinsic light, of natural affinity to reason, of self-evidencing power? If there be any such, it must be admitted that they cannot in themselves fall within the province of science, although the testimony and assent to them may. Where reason stops science must end.

Reason must be free.

(2) Reason in its investigation of religion must be completely free, *i.e.*, subject to no other laws than those which are inherent in its own constitution. In regard to most sciences there is no need to insist that the method of science is one in which reason is free, because all who occupy themselves with these sciences acknowledge it. But in regard to theology it is otherwise. All who call themselves theologians are by no means disposed to admit that reason, in its search for religious truth and in its efforts to construct theological science, must be absolutely free; on the contrary, many of them hold that the church or the Bible, tradition or the common sense of humanity, must be allowed to have a coordinate or even superior jurisdiction. The proposition laid down implies that, if any view of this kind be true, theology is essentially different from science, and it is vain to speak of scientific method in theology. It implies that all claims to religious authority must be based on and conformed to reason, and that all the deliverances of every professedly religious authority must be submitted without reserve or restriction to the reason of the theologian before he can make a scientific use of them. This leads us to another proposition.

Reason limited by its own laws.

(3) The only ascertainable limits of reason in the investigation of religious truth, as of other truth, are those which are inherent in its own constitution; and in the search of religious truth, as of all other truth, reason ought to go as far as it can go without violation of the laws of its own constitution. Reason has its limits in its own laws. It is the business of psychology and logic to discover what these laws are. When they are known the powers of reason are known, because reason can never claim to be irrational. It is useless, however, to attempt to mark off the external or objective boundaries of rational research. Human inquiry has no doubt, external boundaries beyond which it will never pass, but all apparent boundaries of this kind recede as they are approached. There is even absurdity, self-contradiction, in the very attempt to draw any line separating the knowable from the unknowable. To know it one must have already done what we affirm to be impossible,—known the unknowable. We cannot draw a boundary unless we see over it. Reason cannot investigate too deeply any matter whatever, cannot possibly go too far, so long as it remains reason. Its own laws, the laws of evidence and of inference, are the only discoverable expression of its lawgiver's "thus far." When it violates any of these laws it has gone too far, but only then, and then simply because it has ceased to be rational. As long as it conforms to them the farther it goes the better. All this holds good not less in regard to religion than to any other object of investigation, and is an essential condition of the possibility of religious science.

Reason deals with evidence.

(4) In the study of religion, as in every other department of study, reason should admit nothing as true without sufficient evidence, while rejecting nothing sufficiently proved by evidence of any kind although it cannot be proved by evidence of another kind, or although it may be imperfectly understood or have unsolved difficulties connected with it. Theology is sometimes said to be a doctrine or science of belief or faith (a "Glaubenslehre"). Not a few, however, of those who say so regard belief or faith as essentially inclusive of reason, in the form of an immediate apprehension of primary truth or self-evident fact; in which case theology is only a Glaubenslehre in common with other sciences, and belief or faith is in no special mode or measure its foundation. But, whenever by belief or faith is meant mere belief or faith, a belief or faith independent of and unconformed to reason. the apprehension and appreciation of truth,—to affirm that theology is based on such belief or faith is to represent it as so unlike every other science that it clearly cannot be a science at all. For all belief or faith we are bound to have real evidence, and enough of it. But we have no right to reject any real evidence because there is not more or because there is not evidence of some other kind,—no right to neglect to follow any light there is because it may be dim, and much around it may be dark,— no more right to refuse to accept any well-established conclusion as to God and religion because there is great uncertainty as to the essence of religion, and because God in His absoluteness and infinity immeasurably transcends our highest thoughts, than we have to ignore or contest the conclusions of physical science because we cannot tell what matter is, and because we find that every hypothesis as to its nature brings with it many doubts and difficulties.

The foregoing conditions are perhaps the most general and fundamental of those to which reason must conform if it would originate and follow a scientific method in theology.

Sources of religious truth.

The next question which demands an answer is, Whence are the data to be derived on which reason must operate in religious apprehension and theological investigation? What are the sources of religious truth? Reason has not the truth in itself, but in order to possess it must find it. As the eye has not physical light within itself, but merely so corresponds to it as to apprehend it, not otherwise is it with reason and intellectual light. By sources of religious truth can only be meant the media through which God manifests Himself,—the ways by which He makes Himself known; and the physical world, finite minds, human history, Scripture, and the *testimonium Spiritus Sancti* may all be maintained to be such sources. The atheist and the agnostic will not allow that there are any sources of religious truth; the deist and the rationalist will only admit the claims of general revelation, the exclusive Biblicist only of Scripture; and the mystic will trust chiefly to special spiritual illumination; while the theologian of broader view will hold that all the ways indicated are sources, seeing that in and through them all knowledge and experience as to God and religion may be acquired, and must contend that in the study of theology none of them is to be ignored or excluded, underestimated or overestimated, but all are to be duly considered, and the information supplied by each to be taken in connection with that supplied by the rest. The sources are distinct, but not isolated. The light from each combines and harmonizes with the light from all the others. The revelation of God in nature is presupposed by that in Scripture, and Scripture contributes to unveil the spiritual significance of nature. Without the light which the human mind supplies there can be no illumination from any other source, and yet all the light of the human mind is gained in connection with the light from external sources. History gradually evolves the significance of nature, mind, and Scripture, yet cannot be understood if dissevered from the creation in which it is placed, from the mind of man in the principles and faculties of which it is rooted, or from Scripture as the record of the development of a plan of redemption which gives unity and meaning to the whole historical movement. However deep and full a source of religious truth the Bible may be, it is neither independent of other sources nor a substitute for them; on the contrary, while casting light on them all it likewise receives light from them all. The living apprehension of spiritual realities presupposes a discernment which the Divine Spirit alone can give; yet that Spirit, according to the testimony of Scripture, speaks not of Himself, but only in conformity with what has already been uttered by the Father and the Son. It would obviously neither be consistent with the scope nor possible within the limits of an article like the present to determine the distinctive features, natural spheres, and various relationships of the media of revelation or sources of religious truth, but a sufficiently thorough investigation having this aim may safely be pronounced to be one of the chief desiderata of theological science.

Process of theological method.

The facts of natural theology;

of Biblical theology:

of comparative theology.

The process of theological method itself has next to be considered. Its first step is the ascertainment of the relevant facts. But these are all the facts of nature and history, all the truths of Scripture, and all the phases of religion. The various departments of theology are based on and inclusive of various orders of these facts, and each order of facts must be ascertained and dealt with in appropriate special ways. Thus the relevant data of natural theology are all the works of God in nature and providence, all the phenomena and laws of matter, mind, and history,—and these can only be thoroughly ascertained by the special sciences. The surest and most adequate knowledge of them is knowledge in the form called scientific, and therefore in this form the theologian must seek to know them. The sciences which deal with nature, mind, and history hold the same position towards natural theology which the disciplines that treat of the composition, genuineness, authenticity, text, development, etc., of the Scriptures do towards Biblical theology. They inform us, as it were, what is the true text and literal interpretation of the book of creation. Their conclusions are the premisses, or at least the data, of the scientific natural theologian. All reasonings of his which disregard these data are *ipso facto* condemned. A conflict between the results of these sciences and the findings of natural theology is inconceivable. It would be a conflict between the data and conclusions of natural theology, and so equivalent for natural theology to self-contradiction. Then, the data of Biblical theology are all the words contained in the Bible viewed in their appropriate positions and historical connections, and what these are and signify can only be ascertained by the processes of historical criticism and of hermeneutics. Biblical theology is the delineation of a section of the history of religious ideas,—that section of which the traces and records remain in the Bible. But the Bible comprehends many strata of writing, deposited at different times, and collocated and connected in various ways, and the history of its composition, the age and succession of its parts, must be ascertained before we can exhibit the history of its contents, the course of the evolution of its ideas. If the theories of recent critics as to the formation and relationship of the component portions of the Old Testament be true, the view taken of the development of Old Testament theology must be very different from that formed on the supposition that the traditional theory is correct. And which theory is correct is a question of fact which can only be decided by dispassionate and thorough critico-historical investigation. So false readings must be distinguished from true, erroneous translations from correct, and appropriate from inappropriate interpretations, which presupposes an adequate measure of linguistic, grammatical, and exegetical knowledge and skill. The religion of the Bible, however, is but one of a multitude of religions which have left traces of themselves in documents, monuments, rites, creeds, customs, institutions, individual lives, social changes, etc.; and there is a theological discipline—comparative theology—which undertakes to disclose the spirit, delineate the character, trace the development, and exhibit the relations of all religions with the utmost attainable exactitude. Obviously the mass of data which this science has to collect, sift, and interpret is enormous. They can only be brought to light and set in their natural relationships by the labors of hosts of specialists of all kinds. That hypotheses in this domain will for long arise and vanish with disappointing rapidity is only what is to be expected from its vast extent, the amount of its buried wealth, the gradual and fragmentary way in which its contents must be disinterred, the losses and changes which have occurred in the course of time, and the constant suggestion of fresh interpretations of ancient texts and new solutions of old problems which must come from unceasing discovery. Some theological disciplines, it must also be observed, presuppose others, and have consequently among their data the conclusions of those other disciplines. All doctrine, for example, founded on special revelation presupposes doctrine founded on general revelation; all Christian theology must imply and incorporate natural theology. Christian dogmatics has to make use of the results of natural theology, Biblical theology, and comparative theology, and to raise them to a higher stage by a comprehensive synthesis which connects them with the person and work of Christ, as of Him in whom all spiritual truth is comprehended and all spiritual wants supplied. The conception of it prevalent until lately, as a system formed of generalizations and inferences from texts of Scripture, answers properly to no theological science, but much more nearly to Biblical theology than to Christian dogmatics.

Appropriate methods of dealing with these data.

When religious data have been ascertained, the materials of theological science have been obtained, but the scientific edifice itself has still to be constructed. The general truths involved in particular disclosures have to be evolved; the laws of the development of phenomena have to be discovered; elements have to be reached by analysis and comprehensive views by synthesis; laws and facts, fundamental and derivative principles, have to be exhibited in their natural organic connection. This can only be done aright by right methods, and only by a variety of methods. No one-sided process can be appropriate or sufficient. The method must conform to the nature of the matter dealt with and to the end that has to be attained. Theology includes a variety of sciences or disciplines, and these differ so greatly in character that they plainly cannot be studied aright if studied precisely in the same way. Some of them are more allied to criticism, others to history, and others again to philosophy. In some deduction can manifestly have little place, while in others there is no obvious reason why it should not be largely used. There is no kind of science which, with its special processes, may not be called on to contribute to some department of theology. There must be, therefore, in theology need and scope for a great variety of applications of method.

Practical investigation essential.

It is easy, however, to exaggerate the importance of acquaintance with the formal rules of method laid down by logicians. The theory of method must be preceded by practice—true theory by successful practice; and the ablest practitioners are always only to a small extent guided in their practice by conscious reference to the rules of method prescribed by logicians. In theology, as in all other departments of science, a man can only become an investigator by investigating. And whether he will become, through the practice of investigation, a successful investigator or not will depend far more on his general intellectual character, his ingenuity, originality, tact, and sensibility, his familiarity with the relevant facts and with the researches which are really bringing new truths in his department to light, his perseverance and diligence, than on his knowledge of what the theorists on method have taught as to its nature and requirements. Yet, of course, such instruction as logical theory can give is not to be despised, but to be received and acted on with all due appreciation.

Method must be largely inductive.

When the data of the theologian are before him as particular facts, it is obvious that he must so enumerate and classify, so analyze and generalize, so correlate and combine them, as to elicit from them the principles which they imply, before either his procedure or results can be properly characterized as scientific. In other words, a method which starts from particulars must, in order to be scientific, be largely inductive. But in theology, as in all other departments of knowledge, the only induction which is of any value is more than any mere summation or combination of facts. This is not the place for a discussion of the nature of a true induction; but on any view it must hold good that to understand aright what induction in theology is we must know what is implied in all that is comprehended in it,—the ascertainment and collocation of facts, the discrimination of their characteristics, the classification of them, the analysis of what is complex, the synthesis of what is partial, the tracing of uniform relations, the inferential act, etc. Much which would not be without interest or use, or even some degree of novelty, might be said on all these points. Numerous as have been treatises on theology, there has not as yet appeared a single earnest attempt to expound the nature of method in theology; even the many works professedly dealing not only with the encyclopædia but with the methodology have, in reality, quite ignored theological method proper. The present writer can only here note the desideratum; to supply it would require a special and lengthened discussion. The so-called methods of induction—the methods of agreement, of difference, and of concomitant variations—are as applicable in theology as in physical or mental science. They are not, properly speaking, processes of induction; they are merely rules for testing inductions. Their value, of course, is not thereby lessened.

Number of data required varies with nature of the questions considered.

The theologian, not less than the physicist, must be on his guard against fancying that the validity or certainty of his inductions is to be estimated by the number of his instances. Many who have undertaken to prove the Divine existence by the cosmological and teleological arguments have made the fatal mistake of supposing that all that was needed was an accumulation of what they deemed examples or illustrations of Divine wisdom. They have overlooked that what is, above all, necessary is to show the truth of the principles of causality and finality, and the legitimacy of those applications of them, which are involved in the cosmological and teleological arguments. They have spent their strength on what is easy, superficial, and indecisive, and had none left to deal with what is difficult, deep, and of vital moment. They have failed to apprehend that the essential question at issue is not, What or how many appearances of order and of adaptation may be traced in the various provinces of nature? but, Do such appearances *in any case* warrant an inference to a supernatural intelligence and purpose? In like manner many dogmatic theologians have seemed to think that in order to establish a doctrine it was enough to cite a number of texts in its favor. Often their doctrines would be more easily believed if their texts were fewer. Often in the Westminster Confession, for example, where the doctrine causes no difficulty, the texts cited in connection therewith are quite inadmissible as proofs. Induction requires the strictest regard to relevancy. Whether the data for the proof of general truths in theology must be many or may be few will largely depend, as in physical and mental science, on the nature of the truths. When Newton had made out that the law of gravitation explained a single fact, applied to the moon, no person who fully comprehended his demonstration could seriously doubt either of the certainty or of the universality of the law. It was a case of a vast intellectual conquest achieved by one decisive victory. What remained was merely to take possession of what had been won, and to explain certain apparent anomalies. On the other hand, when Mr. Darwin published his *Origin of Species*, he had already accumulated, with amazing industry and ingenuity, and through the uninterrupted investigations of many years, a multitude of observations and considerations in support of the general propositions therein enunciated as laws of biological evolution. Of similar observations and considerations there has since been an enormous increase. Yet the so-called Darwinian laws are still under discussion. Why has their proof or disproof been so different a process from that of the establishment of the law of gravitation? Largely because they are in themselves so different in nature. Laws of evolution can only be reached through the minute investigation of a far greater number of changes and appearances than laws of persistence. The discovery of truths of becoming may not be a more difficult but it is certainly a more delicate and complex process than the discovery of truths of being. Now this distinction not only emerges in theology but pervades it. In some departments of theology the laws to be discovered are laws of evolution, while in others they are laws of existence. Hence the method to be followed in the former must be predominantly chronological and genetic, in the latter predominantly analytic and synthetic. For example, in Biblical theology and comparative theology the inductive process must be of the kind appropriate in historical investigation, whereas in natural theology and Christian dogmatics it must be of the kind appropriate in systematic investigations into which considerations of time, place, and circumstance do not enter. The faculties of mind and processes of method implied in the complete comprehension of religion as a concrete manifestation of spirit are those which are of prime moment in the historical disciplines of theology; the faculties of mind and processes of method involved in the clear apprehension of the truths and laws of religion in its abstract or essential nature are those chiefly requisite in the theoretical disciplines of theology; and, speaking generally, complete comprehension of the concrete presupposes a more minute and exhaustive acquaintance with particulars than does a clear apprehension of the abstract. To determine with scientific precision and thoroughness, for example, what were the stages of the development of doctrine in the Bible, or even to trace with such accuracy and completeness as the data supplied by the Bible and auxiliary sources permit the growth of single important ideas, as, *e.g.*, election, holiness, atonement, and kingdom of God, demands laborious critical investigation and comprehensive and minute historical knowledge. Given, on the other hand, the Christian ideas of God and of man, and the fundamental relation between God and man cannot be otherwise conceived by enlightened reason and conscience than as one of salvation through faith and not by works. True, as all physical nature obeys the law of gravitation, so all Scripture and spiritual experience testify to the power of the principle of faith; but then, also, as the decisive proof of the former lies in the thorough elucidation of any phenomenon which exemplifies it, not in the collection of numerous illustrative phenomena, so the decisive proof of the latter lies in an adequate analysis of any portion or form of the life of genuine faith, not in the accumulation of examples of faith drawn from the Scriptures or other records.

Historical and thetical inductions.

The two methods of induction to which reference has just been made—the historical and the thetical—are to be carefully distinguished but not absolutely separated, and still less exhibited as antagonistic. Both have specific and appropriate functions; neither is exclusively legitimate or can alone accomplish the work of science. The historical method by itself can only yield history. It has done all that can in any circumstances be reasonably expected from it when it has enabled us accurately to realize the course of the history studied, or, in other words, when it has given us a correct reflection of the history. If, not content therewith, we would further ascertain the nature and laws of the factors which formed the history we must supplement the historical with the thetical method. The historical method leads only to history, and in no form or province is history science. Science even of history, or of any department of history, cannot be reached simply by the historical method, but further requires recourse to the processes of positive science. Comparative theology, Biblical theology, and the history of Christian doctrines are most valuable theological disciplines, but, inasmuch as their methods are purely historical, their results are also purely historical, and they are not, rigidly speaking, sciences, but only sections of the history of religion. The tendency to substitute history for science, and the historical method for the scientific method, is prevalent in the present day in theology, as well as in ethics and jurisprudence, social philosophy and political economy. Obviously, however, it rests on exaggeration and illusion, and confounds things which ought to be distinguished. Neither history of the objects of a science, nor history of the ideas or doctrines of a science, is science, and the historical method of itself can only give us in connection with science either or both of these forms of history. It is, therefore, inherently absurd to suppose that the historical method can be sufficient in such theological disciplines as natural theology and Christian dogmatics. In reality, it is not directly or immediately available in the study of these disciplines at all, and that just because it does not directly or immediately yield theory, doctrine, science. Only he who knows both the history of the objects and the history of the ideas of a science, and especially of a psychological, social, or religious science, can be expected to advance the science. In the sphere of religion, as in every other sphere, to confound history with science is to eliminate and destroy science; but in no sphere is knowledge of history more a condition of the attainment of science, and historical research, properly conducted, more serviceable to scientific investigation, than in that of religion. To the historical method we owe, not only the historical disciplines of theology, but also in a considerable measure the recent progress of its positive or theoretical disciplines. It can never, however, be, as some fanatical disciples of the historical school would have us to suppose, the method of these last.

Complex problems demand comprehensive inductions.

The inductions of theology, even in its systematic or non-historical departments, often require to be very careful and comprehensive in order to be conclusive. Theories or doctrines like the Christian dogmas of the Trinity, incarnation, and atonement were only arrived at through the labors and controversies of many generations of theologians. It could not be otherwise. These dogmas, simple as they may seem to a superficial glance and untrained eye, are in reality very complex organisms of thought, only capable of being formed by a long process of evolution. They are theories inclusive of many theorems. They comprehend a number of directly constitutive propositions and a still greater number of propositions subordinate and subsidiary to these. Every proposition which they involve should be the expression of real and relevant facts. As wholes they ought to combine a multitude of particulars of different kinds, and even of kinds the harmony of which is far from obvious and needs confirmation. Whoever intelligently accepts any one of these dogmas must, by necessary implication, reject a host of hypotheses regarding its subject, as either inadequate or positively erroneous. Inasmuch as they are not consistent with or are contrary to the dogma, he is logically bound to repudiate them, and yet he is only logically entitled to do so if his proof of the dogma have been so comprehensive and complete as to include their separate and collective refutation. The establishment of the whole truth is only possible through the disproof of all the opposing errors. How the inductive method is applied in theology, however, will be better understood by the examination of a particular exemplification of it than by a general description; and, perhaps, as regards at least form, a more careful or elaborate exemplification could hardly be pointed out than that exhibited in Dr. Crawford's treatise on the atonement. An examination of it will show how very complex in reality may be a doctrine which is very simple in appearance, and how comprehensive, therefore, must be the inductive procedure necessary to establish it and to warrant the rejection of the hypotheses which must seem to one who accepts it to err by excess or defect or to be absolutely false.

The deductive element indispensable.

The inductions of theology, like those of other sciences, are seldom or never mere or pure inductions. They would be useless if they were. The examples of pure induction given in treatises on logic may serve their purpose, the illustration of the nature of ratiocination, but they are not reasonings of a kind which can increase positive knowledge. The abstraction of induction from deduction may be needed to exhibit its distinctive formal character, but it is fatal to its practical efficiency. In all reasoning meant to increase our knowledge of objects, induction must receive from deduction some measure of assistance and guidance. This certainly holds true in theology. In regard to the doctrine of the Trinity, for example, the most difficult questions involved turn largely on the signification and application of the terms employed in its expression. These terms must be somehow defined, and definitions once introduced cannot fail to be used to some extent as principles of deduction. They are often largely so used by those who are quite unconscious of making any use of them, and who have no suspicion that the course and character of their reasonings are modified by them. Definitions often secretly introduce a great amount of hypothesis and deduction into reasonings imagined to be exclusively inductive. Further, principles of deduction are directly and explicitly introduced. The truth of the catholic doctrine, or indeed of any doctrine, of the atonement, for example, cannot be proved purely by induction. It is necessary to start with some assumption as to the authority of the Scriptures, or at least as to the authority of those whose teaching is contained in the Scriptures. That assumption itself should, it is true, be proved by a process of apologetical and critical reasoning which is in the main inductive. It cannot, however, any more than the doctrine of atonement, be proved by a purely or exclusively inductive process, *i.e.*, without some co-operation or participation of deduction; and, once proved, it becomes a principle of which a deductive use is made. Every particular statement of Scripture is read and interpreted in the light of it. So far as this is the case, deduction underlies all the inductions of doctrine based on the statements of Scripture. Of course, the dogmatic theologian, in so far as he founds on Scripture, is bound not to presuppose more than he is prepared to prove as a Christian apologist or Biblical critic and interpreter. The assumptions made in systematic theology ought to be the firmly ascertained results of its subsidiary sciences. And the less assumed the better, as the relevancy of the reasoning employed will be so much the more widely acknowledged. Every additional assumption diminishes the number of persons who will grant the principles on which the argumentation proceeds. When, for instance, a doctrine like plenary inspiration is assumed as the basis of an argument for the atonement, the number of persons who can be benefited by the argument must be few. Those who will grant plenary inspiration are not likely to require to be convinced of the truth of the ordinary doctrine of the atonement; they are almost certain to be already convinced. On the other hand, a man may have loose or vague views of inspiration, and yet it may be possible to satisfy him that the doctrine of the atonement is well founded. The proof of the doctrine of the atonement may receive support and confirmation from the proof of the doctrine of plenary inspiration, but ought not to be made dependent on it.

Systematization.

Scientific method has not only to ascertain the facts and data of science, and to discover its laws, but also to distribute and co-ordinate its contents. And this last is likewise an important function. Science is system. To exclude system from science is to suppress and destroy science. The spirit of system is in itself nothing more than the spirit of order and unity. Without unity and order—that is, without system—there is no science; instead of it there can be only confused ideas, isolated opinions. It is absurd to condemn either system or the spirit of system in theology or any other science. To systematize is an intellectual necessity; to systematize aright is a happy achievement and an immense boon; it is merely systematizing erroneously which is evil. Theology, by professing to be a science, pledges itself to systematize in a scientific manner. By claiming to be the science of religion it undertakes to exhibit the truths of religion in their proper relationship to one another, in their organic unity and essential interdependence. Thus to proceed is necessary to it, not only as a consequence, but also as a means of the development of its constituent dogmas, for no doctrine can be truly and fully evolved in isolation, but only in connection with kindred doctrines and through the general growth of the science or system to which it belongs. Increase of insight into any one truth brings with it clearer views of all contiguous and related truths, and the collective light thus gained illumines each particular to which it extends. To apprehend more distinctly the relations between either facts or theories is to understand better the facts or theories themselves. To comprehend any single doctrine aright we must study, not merely its special data, but those of allied doctrines, trace its connections with those doctrines, and view both it and them as parts of an organic and harmonious whole. Hence the endeavor to systematize the contents of science should not merely follow the formation of its separate doctrines, but likewise accompany and participate in the process of their formation. Wisely conducted systematization is entitled to be deemed an aid to discovery. It reveals where exploration is needed, and indicates the directions in which research will be successful. It is the highest form and effort of synthetic thought, and synthesis is a not less necessary and fruitful operation in scientific method than analysis.

Abuse of system.

Unfortunately it cannot be denied that there has been a vast amount of erroneous systematizing in theology, and that it has done a vast amount of harm. Doubtless much of the aversion felt and expressed to system in theology is to be traced to the imperfect, artificial, false character of many theological systems. Instead of exhibiting religious truths in their real significance and interdependence, theological systems have often disguised and disfigured, cramped and contorted these truths, or even ignored and rejected them. How, then, is a true and appropriate system to be distinguished from one which is false and imperfect? In various respects, which can here be merely mentioned.

Requisites of a true theological system.

Thus, first, a true system is natural and not artificial. In equivalent terms, it is directly derived from the character of the matter of which it treats, and not arbitrarily imposed on that matter from without. Every system of thought, whether true or false, must, of course, be the product of intellect, but no true system is a mere invention of intellect, a mere subjective creation interposed between the mind and things; it is, on the contrary, a representation of the real natures and relations of things. The human intellect can only construct a true system by finding in and among facts the connections and harmonies which are actually there. But to do this may require more labor than is agreeable, or may contravene some cherished prejudice, or may not be recognized to be the sole legitimate procedure, and so it may devise, instead, a formula or scheme of thought suggested by some idea drawn from an extraneous source, force that scheme or formula upon things to which it is inappropriate, and so construct a system which is artificial and erroneous. Most sciences have suffered from artificial systematization of this kind, but probably none nearly so much as theology. Metaphysical philosophy has always sought to shape and modify religious and even distinctively Scriptural truths according to its own ideas, methods, and dogmas. Paul and John have often been merely the masks through which Plato and Aristotle have taught. Hegelian divines have passed all religious beliefs, all Scriptural doctrines, through the dialectic devised by their master, and, whatever those beliefs and doctrines may have been before subjection to the operation of that wonder-working machine, they have always come out ground into Hegelian notions. Jurisprudence exerted a similar influence, owing to its having been the only science which was studied with zeal and success in the Latin world when theology began to be independently cultivated by the Latin Church. The Latin mind was so possessed by juristic or forensic ideas that the Latin fathers could not avoid looking at the gospel through them. This way of viewing it is still familiar. The so-called federal school of theology, long and widely influential, exhibited the whole system of religious truth according to the analogy of a covenant, —a succession of covenants between God and man, in other words, according to a conception which is essentially juristic and political, not intrinsically and properly religious. The making of a metaphor in this manner the basis of an entire system of theology is far from uncommon. Thus, because sin may be likened to disease or to darkness or to death, and holiness to health or light or life, not a few would conceive of all religious truth according to these similitudes, and do violence to the reality when it does not easily adapt itself to the moulds which they have chosen for it. Dr. Chalmers, for instance, distributed all systematic theology into a study of the disease and a study of the remedy, and treated the doctrine of the Trinity merely as an appendix. At present, owing to the dominancy of physical science, there is a strong temptation to work upon spiritual facts with physical categories, and even to identify, *i.e.*, to confound, the spiritual with the physical. Hence we hear of natural law, in the sense of mechanical or biological law, in the spiritual world.

Secondly, in a true system of theology the material and formal constituents of knowledge will be duly combined, but not in a false system. No true system of theology can be constructed simply by logical deduction from abstract conceptions, from *a priori* assumptions, from self-evident axioms. Mere reasoning from data so insufficient as these may be made plausible and imposing by being thrown into syllogistic, dialectic, or mathematical shapes, but it cannot be made truly profitable and productive. When the Wolfians had presented theology in the semblance of geometry, they had merely succeeded in dressing it in masquerade and binding it with fetters. Reason can only work effectively in theology when it is in possession of a large and close acquaintance with Divine things and acts harmoniously with the whole spiritual nature. On the other hand, without the application of logical reflection to the truth implicitly contained in the sources of religious knowledge, without the help of definition, induction, deduction, and all the processes involved in analysis, generalization, judgment, and reasoning, we never could reach a scientific system at all. Such a system is not simply an aggregation or accumulation of the data and constituents of religion, but the product of all the activities and forms of thought which give to the contents of religious experience the order and organization which theology, as science, demands.

Thirdly, a true system is one in which unity is the result of the conciliation of all relevant principles, even although they may be apparently antagonistic, while a false system is one which bases itself on some particular principle or idea to the exclusion of others, also legitimate. In a true system unity is produced by harmonizing differences; in a false system it is produced by ignoring differences. A true system of theology is one which grows out of the struggle of opposing elements and recognizes the validity and significance of all religious truth. It is not, for example, so based on Divine sovereignty that injustice is done to human liberty, or so based on free will that God's agency is largely ignored, but it assigns to both Divine efficiency and human action their proper place, and does so, not merely by maintaining the truth of both, but also by exhibiting their relationship and harmony.

Fourthly, in a true system all the members are not merely included, connected, and classified,—they are also unified through reference to a centre. A true system must be a unity of members pervaded by a common life. In its remotest members must be traceable the pulsations of its heart. Only of late have theologians begun clearly to recognize that this characteristic of a true organic system must be taken into account in the formation of their science. Long after they were fully alive to the importance of treating of each head of doctrine or article of faith, each separate theological locus, they felt hardly any interest as to how the various doctrines, articles, or loci were to be connected. They were often content to take the order of arrangement from some external source, some creed, confession, or catechism. It was a step in advance when, although still arranging the dogmas merely in a series, they endeavored to give each dogma its place, on the ground of its natural and intrinsic relationship to other dogmas. Theologians have, indeed, differed much as to what is the proper *seriatim* order. One, for example, has begun with the nature and state of man, a second with the being and character of God, a third with the Divine authority of the Scriptures, and a fourth has followed the order of the Divine dispensations. Yet there need be no doubt that there is such an order, one in which every dogma is exactly where it ought to be. This order, it may also be safely affirmed, can only be one of advance from the simpler to the more complex. An order in which each dogma has before it only its natural antecedents, and after it only its natural consequents, must be one of continuously increasing complexity. The spirit of order and of system cannot rest, however, in the series. It must classify as well as connect the doctrines. This also may be accomplished in various ways, and even when there is general agreement as to what are the natural groups, there may be considerable difference of opinion as to their delimitation. But the most perfect distribution by classification, if unsupplemented, must be unsatisfactory. A still higher kind of unity has to be attained. It is that of the only unity which is truly organic. It is that of co-ordination and correlation through a single central principle. An intellectual system, a system of science or doctrine, can only have this unity, and be in consequence a true system, when all its particular truths and various departments or divisions of truth are connected with one another and combined into a whole by reference to a common and central truth. The necessity of conforming to this condition of systematizing has now begun to be felt among theologians, and hence in several modern systems of Christian dogmatics the doctrines are not merely distributed into groups, but an attempt is also made to find a centre for the whole system in a single pervasive idea. Such a centre Rothe, for example, finds in the religious consciousness, a consciousness of sin and of grace; Kahnis in the doctrine of the Trinity; and Thomasius and H. B. Smith in Christ Himself, His person and work. So far as Christian theology is concerned, the last of these views is doubtless correct. Christian theology, like Christianity itself, must be Christocentric. All its doctrines either directly and immediately relate to Christ's manifestation of God and redemption of man, or are the antecedents and consequents of those which do. To Christ the entire system owes its distinctive character. For general theology, on the other hand, the central and vital idea can be no other than that of religion itself. It must obviously be one derived from the domain of the science itself, and indeed from the essential nature of the object of the science. As it would be an error to seek the principles of biology elsewhere than in "life," or of psychology elsewhere than in "mind," so must it be to seek the principles of theology elsewhere than in "religion." Theology is the science of religion, and in the true idea of religion should be found the central and constitutive principle of the general system of theology. That it can be found therein will appear as we proceed.

Must the work of method in theology end, however, even with the formation of a system which answers to the requirements just indicated? Is there no still higher procedure or application of theological method legitimate? This is to ask if there be any place for a speculative method in theology, and if speculative theology rest on any solid basis.

Speculative method in theology.

The history of theology might, perhaps, suffice of itself to show, on the one hand, that speculation has a large and legitimate place in the sphere of theology, and, on the other hand, that its place is one the limits of which are difficult to fix or keep within. Christian theology was initiated by Gnostic speculation, grandly reasonable in aiming at the exhibition of Christianity as the absolute truth and absolute religion, but otherwise wildly extravagant. An Origen and an Augustine owed largely to speculativeness both their successes and their failures. The defects of scholasticism were due more to misdirection of the reflective understanding than of the speculative reason, and it was especially the speculative and the mystic divines of the Middle Age who opened up the way to modern thought and modern theology. Men like Nicholas of Cusa, Bruno, Telesio, and Campanella, looking from the heights of speculation, saw some aspects of religious truth which the Reformers, standing on lower if safer and less cloudy ground, overlooked. A Descartes and a Spinoza, into whatever errors they may have fallen, certainly did much, and in a directly speculative manner, to enlarge and advance the philosophy of religion. Kant supposed that, by his critical researches into the nature and limits of knowledge, he had made an end of speculative theology and done what would effectually deter reason from speculative adventures. It soon became apparent that his expectations had been doomed to disappointment, that in reality he had excited speculative reason to extraordinary activity and even audacity, and inaugurated an era of theology far more speculative than any which had preceded it. The great speculative movement in philosophy headed by Fichte, Schelling, Hegel, Baader, Krause, and others passed on immediately into the sphere of theology, its leaders themselves proceeding to apply their principles and methods to the explanation of the doctrines and phases of religion. Theologians by profession soon followed in their footsteps. Daub and Marheinecke constructed systems of Protestant dogmatics by means of Hegel's dialectic. Strauss, Baur, and their followers reached by the same method negative and antichristian results, bringing out the contradictions between the doctrines of the church and the speculative truths to which it was held that they should give place. Many theological systems of an almost exclusively speculative character have since appeared in Germany. Weisse's *Philosophische Dogmatik* and Rothe's *Theologische Ethik* are good typical instances. And, while not so predominant, the speculative use of reason is yet conspicuous in the treatises on Christian dogmatics of Dorner, Martensen, Schöberlein, Hofmann, Liebner, Biedermann, and others. In the department of philosophy of religion a speculative procedure is not less frequently followed, either as alone appropriate or as a necessary supplement to the genetic and historic method. Rosmini, Gioberti, and Mamiani inaugurated in Italy a speculative theology second only to that of Germany. Contemporary French theological literature can boast of at least one work displaying real speculative power,—the *Philosophie de la Liberté* of M. Secrétan. In America Hickok, Bushnell, and Mulford may be named as having shown confidence in the competency of speculative reason in the spiritual sphere. In Britain Principal Caird has argued in favor of a speculative procedure in theology with rare skill in his *Introduction to the Philosophy of Religion.* On the whole, however, both in America and Britain, the speculative method has received little recognition from theologians. But this, of course, may be held to be partly cause and partly effect of the want of life and originality, of thoroughness and truthfulness, of ordinary American and British systematic theology.

Is there, then, room and need in theology for the speculative method? The answer must depend on what is meant by speculative method. There are kinds of so-called speculation which are plainly illegitimate and inapplicable. Thus, some have represented speculative theology as part of a philosophy of which the whole system is deduced in a purely and strictly logical manner from an *a priori* principle, idea, or datum. On this view the speculative thinker somehow apprehends an absolute first of thought or being, or both, and then from this primary and necessary datum evolves syllogistically or dialectically a whole philosophy, which includes a whole theology. Such speculation may be safely pronounced futile and delusive. It can never reasonably vindicate its choice of a starting-point, for the absolute first of existence and thought can only be that to which the worlds of fact and experience, of matter and of mind, refer us as their ultimate explanation. It ascribes an extravagant power to mere formal thinking. It is only consistent with exclusive idealism and exclusive rationalism, both justly discredited species of philosophy. It makes theology wholly dependent on a philosophy which must be false, since pure reason cannot, as it assumes, spin out of its own essence or out of any single datum the whole system of truth.

The *Theological Ethics* of Rothe.

There is, however, a theology which claims to be at once speculative and independent of philosophy. Such was the theology which Rothe sought to elaborate in his *Theological Ethics*. In the "Introduction" to that work he has fully explained his method. It is, as there represented, the very same method with that of speculative philosophy, but it starts from a different point,—not from pure self-consciousness, but from the religious self-consciousness or God-consciousness. Its primary datum is, according to Rothe, as immediately certain as that of speculative philosophy, the pious man being just as directly sure of God as the natural man is of his own self. Out of this datum it must evolve all its conclusions by an inward logical necessity, and construct an entire theological system of such a nature that every single thought implicitly supposes the whole. Speculative theology thus conceived of needs but a single fact, the datum from which it starts, and that fact must be a self-evident one, given immediately in and by consciousness; all the rest is a succession of inferences deductively obtained. The facts of religion presented in nature, history, and Scripture not only need not but ought not to be taken into account by it, although at the close of its labors its success must be tested by the conformity or non-conformity of its results with those facts.

> "This system of *a priori* thought," says Rothe, "to be successful as a speculation, must be an absolutely corresponding and constant image of the reality; but the speculative process itself takes no thought whether there be such a reality existing, or how the ideas which it constructs are related to it; but, without looking either to the right hand or to the left, it follows only the course of logical necessity, until it has accomplished the whole circle of its ideas, and constructs a complete system. Then first the speculative thinker looks out of himself, in order to compare the system of thought which he has independently constructed with the objective reality, and to assure himself of his correctness by such a comparison; but in so doing he is slipping out of the region of speculative into that of reflective thinking. The necessity of such a verification, indeed, he acknowledges unconditionally, but he distinguishes clearly between the speculation itself and that reflective critical process by which alone such a verification can be realized. With reference to the empirical reality around him, he acknowledges that his speculation is incorrect if his system of thought is not *there* reproduced, but he still persists that he has to complete his speculative labor without any direct reference to it. He concludes rather, from a clear want of correspondency, that he has speculated incorrectly, and can look for his error in nothing else than in his departure from a strict adherence to the laws of logic. Forthwith, then, he destroys his laboriously constructed system; but if he again proceed to construct another, he must proceed in the very same manner as before, *i.e.*, by looking solely into his own thoughts, as though there were no world around him."

Rothe, it will be observed, cannot be charged with having made theology dependent on philosophy. He represented theological speculation and philosophical speculation as starting from different data, as running parallel to each other, and so as throughout distinct. But this was to avoid one extreme by falling into another. It was virtually to deny the unity of thought, and to assume an incredible dualism in the universe of speculation. A theology absolutely separated from philosophy must be even more unsatisfactory than one wholly dependent on it. Then, the method itself proceeds on assumptions unsupported by evidence, yet far from self-evident. It assumes, for instance, that a system of ideas generated *a priori* will be a counterpart of reality, although it is neither inconceivable nor improbable that the characteristics of real existence may be incapable of being determined by the mere logic of necessary thought. Reason should not thus be credited with the extraordinary power of comprehending reality without requiring to apprehend and study it. Another assumption is, that a complete and self-consistent system can only be reached by an exclusively *a priori* procedure, whereas, it is far more likely that such a system will only be attained by a combination of different processes. Again, the primary datum of theological speculation as understood by Rothe—the idea of God—is assumed to be immediately given and immediately certain. But the idea of God is not immediately given or immediately certain. The piety which chooses to affirm so is a piety capricious in its affirmations; the speculation which starts from such a foundation starts from an assumption easily shown by psychology and history to be erroneous. Rothe went even farther astray. He represented not only the bare consciousness of God but the Christian, yea, the evangelical God-consciousness, as a simple and primary datum of consciousness. This was utterly arbitrary. It was to treat as an original apprehension what is indubitably an acquired experience. No *a priori* system—no properly deductive system—can be reasonably imagined to have such a starting-point. For these and other reasons, theological speculation of the kind advocated by Rothe may be rejected.

The *Schriftbeweis* of Hofmann.

Still another species of theological speculation, however, has been attempted and commended,—one which seems more modest, and claims to be more distinctly Christian. It is the method advocated and exemplified in the *Schriftbeweis* of Von Hofmann. He, instead of starting like Rothe with the religious consciousness, chose to start from a real concrete fact, what he calls the Christianity of the Christian,—a Christianity which he supposes to have acquired in the Christian a separate standing of its own, in virtue of which, and independently even of Scripture, it is self-evident certain truth sustained and authenticated by the Spirit of God. From this fact or experience, expressed in its simplest and most general form, as a personal relationship or fellowship between God and man through Jesus Christ, Hofmann would deduce the whole theological system by a process of "thinking within" the central fact, so as logically to evolve from it its manifold wealth of contents, and would refrain on principle from looking outwards, and taking into account the religious facts presented by history, experience, or Scripture. Now, in this system also, speculation is in excess. Such a speculative deduction of facts from facts as is contended for is impossible. Facts are not so involved in one another that they can be evolved from one another by mere thinking, and still less so that from one fact a whole system of facts can be thus evolved. From a single bone, indeed, of an animal which he has never seen or heard of a naturalist may in thought correctly construct the whole skeleton, but not by thinking within or from the one fact before him, but by making use of all the knowledge he has acquired of the structure of animals, of the relations of bones to bones. Dr. Hofmann himself was quite unable to carry out the method he contended for. His so-called speculative arguments are mere semblances of what they profess to be. Instead of the contents of his system being really "derived" from the simplest expression of the fact of Christianity, new propositions are constantly borrowed from the known contents of Christianity, and added from without to the simplest expression, in order to help out the unfolding of the system. Further, in Hofmann's system of speculation, as in that of Rothe, we are asked to start from an assumption which is not, and cannot be, justified—the assumption that Christianity in the Christian is independent of its objective grounds. Surely every experience may reasonably be called upon to produce evidence of its legitimacy and validity; and, if so called upon, how can it avoid referring to its grounds? It is only by an examination of the grounds of an experience that we can know whether it is an experience of reality or a form or effect of illusion. The fact from which we are told by Hofmann that we must deduce all other facts is only itself intelligible in the light of many of these facts, and even of the Christian system as a whole; it is a fact which has many conditions, and the right understanding of it requires its being viewed under its various conditions, not as abstracted from and independent of them.

Speculation necessary to true systematization;

In the forms indicated, then, speculation has failed to make good its claim to participate in the formation and development of theology. Does it follow that its claim is wholly unfounded? By no means. Speculation in the forms described pretends to an independence of reality and a creative power for which there is no warrant in reason or confirmation in fact. Hence the futility of such speculation is no disproof of the utility of a speculation which will fully recognize reality and directly endeavor to elucidate it. Speculation of this latter kind seems to be a necessary condition of true systematization and a necessary supplement to induction and to all the special methods of particular sciences. In a true philosophy, for instance, science and speculation must necessarily be combined. So far from claiming independence of the sciences, a true philosophy will base itself upon them, and seek to rise above them by means of them. It is only thus that it can hope to reach the ultimate universal and real principle of knowledge and being, without which there can be no rest for reason or unity in the universe. But, having ascended by an analytic and inductive course to the unity of an all-comprehensive ultimate principle, philosophy must endeavor to descend from it in a synthetic and deductive manner, so as to exhibit the whole organism of existence, or to determine how the many laws of science and the many facts of experience are connected with the absolute in being and causation, and through it with one another. It is conceivable that the descent should be accomplished in various ways, and Plato and Plotinus, Descartes and Spinoza, Fichte, Schelling, Hegel, Krause, Gioberti, and others have attempted it each in a way of his own; but two things are obvious, namely, that philosophy cannot consistently decline the task, and that any method it may adopt in trying to perform it must be one essentially speculative. An inductive and analytic method is clearly inapplicable, for the highest and last results of induction and analysis are just what are to be elucidated through being viewed in relation to the one supreme truth or fact. And among the data with which philosophy must thus synthetically or speculatively deal are those of religion. It requires to show how what theology teaches as to God's nature and operations comports with what itself affirms as to the absolute source and ground of existence, and this necessarily commits it to have recourse to a theologico-speculative use of reason. And to a very large use of it if, for example, theism be true; since, in this case, the absolute principle of philosophy can be no other than God Himself, and its highest task no other than to show Him to be the essence of all existence, the light of all knowledge. In this case philosophy must inevitably become in the highest stage of its development a speculative theology.

Nor can positive theology dispense with speculation. It cannot, indeed, begin with it or confine itself to it,—cannot start with some single immediately certain religious fact, and then by mere force of logic evolve and as a supplement to induction.

therefrom a whole theological system. Its data are all real facts of religion, and these it must deal with, in the first place, mainly by observation and induction. But observation and induction will not always alone lead to a satisfactory result. Observation is confined to experience, which gives only the particular. Induction, in so far as it effects a transition from the particular to the general, already involves the activity of speculative reason; it makes discoveries only when guided by theory; it can never of itself reach ultimate truth; and it is manifestly not its function to raise coherent comprehensive systems on their proper constructive principles. Then, the theologian who renounces speculation must deal most inefficiently with the chief ideas and doctrines of his science. Consider the greatest idea of all—the idea of God. Mere observation and induction do not yield the idea. Exclusively applied, they cannot take us beyond the contingent and conditioned, cannot take us beyond atheism and secularism. Waive, however, this objection, and grant that the idea of God may be given, say, through revelation. What sort of idea must it be in the mind of the theologian who refuses to speculate? Merely that of a complex of the attributes predicated of God in the Bible. Surely that is unworthy to be accounted an idea of God at all. The theologian who is in earnest with the idea of God, who would find order and light in the idea, who would think of Him as He is, Absolute Being, Harmonious Life, Infinite Personality, Perfect Spirit, Ultimate and only Complete Explanation of the Universe, must assuredly speculate, and speculate freely and largely, although he ought also to do so humbly and reverently. Even if he would maintain that we cannot have a knowledge of God as He is—that we must renounce the hope of a speculative knowledge of Him, and be content with a merely regulative knowledge,—he will find that he needs, as Kant, Hamilton, Mansel, and Spencer have practically so fully acknowledged, speculation, and much speculation, to support his thesis. The mind is not necessarily relieved from the duty of exercising speculative thought on the nature of God by receiving a special revelation regarding God. Christianity is a proof that such revelation may only increase obligation in this respect. It brought with it a wondrous idea of God, one of marvellous practical efficacy, but one also which forced Christian reason into paths of speculation, which could only be formulated after lengthened and severe speculative labor, and which no intellectually or spiritually quickened soul can accept otherwise than with speculative exertion. And this may show that speculation is as legitimate and applicable within the sphere of Christianity as within that of general theology. The comprehension of Christianity requires that we penetrate to its distinctive and central principle, and view all its contents in the light of that principle. It is only so that we can hope to accomplish either a true systematization or a true elucidation of its contents. The procedure by which this is effected cannot be one of mere formal logic, of pure deduction, or strict demonstration; it must be one which implies a constant reference to facts and inductive results; but still it must be one which is essentially synthetic and speculative.

Relations of the theological sciences.

Theology is a unity, a whole, but a very complex unity, a whole of many dissimilar parts. It may be spoken of in a broad and general way as a science, but not less correctly as a department of sciences. It includes many studies or disciplines which may be cultivated in a scientific spirit and according to scientific methods, and these studies or disciplines, while closely connected, are also clearly distinct. They are by no means mere divisions of a special science. Natural theology and Christian dogmatics are as distinct from each other as physics is from chemistry or anatomy from physiology. Comparative theology and Biblical theology are as distinct from each other as the study of the general history of mankind is from the study of the history of England.

Encyclopædia of theology.

Hence arise a number of problems. How are the theological sciences related to the non-theological sciences and to one another? How are they located in the vast organism of science as a whole? and how are they connected with one another so as to form a smaller organic whole in themselves? What principles have they in common, and what tasks are proper to each? Wherein do they agree and wherein do they differ in their methods of research? These are very important questions. There cannot be an earnest and scientific study of theology where they are overlooked. It is the special task of the theological discipline called "encyclopædia of theology" to discuss and answer them,—or, in other words, to determine the boundaries of theology, to exhibit and explain its inner organization, to indicate its component parts, and to trace their relations both to one another and to the theological system as a whole. This discipline is, therefore, the appropriate scientific approach and introduction to theology and to the various theological sciences.

It is of comparatively little importance whether or not it be itself called a theological science. Strictly speaking, perhaps, it is rather a section or prolongation of that division of general philosophy which treats of the relations of the sciences. One of the tasks of philosophy is to define and distribute, classify and co-ordinate, the sciences, so as to exhibit them as parts of an harmonious *cosmos* or members of a well-proportioned *corpus*. But philosophy, when in the pursuit of its merely general ends, cannot be expected to go into details and to concern itself with all the subdivisions and ramifications of science. It will be content to trace main lines, to appreciate leading principles, processes, and results, and, in a word, to exhibit the organic unity and variety of science as a whole. It will leave the exact and exhaustive distribution and survey of any particular kind or group of sciences to those who are extensively and minutely acquainted with that kind or group of sciences. The comprehensive philosophic survey of any order or department of studies is the encyclopædia thereof. Hence there is encyclopædia of mathematics, of physics, of philology, and of jurisprudence, as well as of theology. Encyclopædia of philosophy, however, comprehends all the departmental encyclopædias of science. And this for the simple reason that philosophy is inclusive and unitive of all science. As *scientia scientiarum* philosophy is, as Hegel has aptly said, "wesentlich Encyclopädie." Hence theological encyclopædia—the encyclopædia of the sciences conversant with religion—may reasonably be held to be essentially a prolongation, a direct continuation, of philosophy.

Theological encyclopædia has had its course determined by the general movement of theology. The various theological disciplines required to be evolved before they could be co-ordinated. The designation "theological encyclopædia" first occurs in its current technical sense in Mursinna's *Primæ Lineæ Encyclopædiæ Theologicæ* (1764). It was only with the publication of Schleiermacher's *Kurze Darstellung des theologischen Studiums* in 1811 that the full scientific importance of the discipline was made evident. It has since been diligently cultivated in Germany, and is at length finding recognition in other countries.

There are, however, serious defects even in the latest and best expositions of it. Two of these may be noted as being so serious that, owing to their prevalence, theological encyclopædia can hardly be said to have even yet entered a truly scientific stage. One is the virtual or express identification of theology with Christian theology. All the chief theological encyclopædists of Germany—Hagenbach, Lange, Räbiger, Rothe, Von Hofmann—follow Schleiermacher in this amazingly absurd procedure. Logically the Brahmanist, Buddhist, and Mohammedan might with equal justice identify all theology with their own. The superiority of Christianity to other religions, the uniqueness of Christianity among religions, does not alter the nature or lessen the magnitude of the error. Every encyclopædia of theology which confounds the general with the special so completely as to identify theology with Christian theology forfeits its title to recognition as scientific; and almost all, even of the latest and best theological encyclopædias, do so. The other fault referred to is that, even in the latest and best of theological encyclopædias, the constituent sciences of theology are not so co-ordinated with reference to a centre as to render apparent their organic connections. The German encyclopædists since Schleiermacher claim, indeed, that they so distribute the various disciplines of theology as to exhibit its natural organization. But the claim is not well founded. In reality, their schemes of distribution have no real unity. They are simply arrangements of the various theological disciplines in a fourfold, threefold, or twofold manner, *i.e.*, for example, as exegetical, historical, systematic, and practical, or as historical, systematic, and practical, or as didactic and practical. But this is merely external classification. It may be faultless of its kind, but it cannot of itself yield more than a superficial and mechanical arrangement of the theological sciences. Theology, to be scientifically surveyed and distributed, must be viewed as a unity, and all its parts must be shown to be included in it, and to have a definite place in it from its very nature and definition, as the science or philosophy of religion. Their relationship to one another must be determined by their relationship to the whole of which they are parts, to that science or rather philosophy which treats of religion as a whole. They can only be unified and co-ordinated in a truly organic manner by their due reference to religion, and consequently proper inclusion and location in the philosophy of religion. This necessity has as yet been only verbally acknowledged by theological encyclopædists.[1]

Philosophy of religion.

There is an all-comprehensive science of religion,—one which treats of religion in its unity and entirety. It alone completely answers to the idea and definition of theology. It is the one general theological science, comprehends and dominates the special theological sciences, so as to be the science of these sciences, and hence, in accordance with the true distinction between philosophy and science, is properly called philosophy rather than science—the philosophy of religion. All philosophy is science, but all science is not philosophy. Philosophy, as distinguished from science, is general or universal as distinguished from particular or special science. This distinction is, of course, not an absolute one, but of degree—of more or less; every other distinction between them, however, is positively erroneous. The one general theological science is appropriately, therefore, termed philosophy. It is the philosophy of religion as there is a philosophy of nature and a philosophy of mind, each inclusive of various sciences. It is of the very nature of philosophy to be both before and after the sciences to which it relates,—to be at once their root and result, and at the same time their bond of union and source of life. And the general theology which may justly be identified with philosophy of religion has undoubtedly held this relation to the special theological sciences. It preceded them, being the germ from which they evolved, the root from which they have sprung; it has grown up along with them, permeating them as their common life; and it also succeeds and transcends them, basing itself on them and perfecting itself by means of them. It is the one generic science of the object with which it deals, and vast enough to comprehend a whole group of sciences, because its object—religion—is so rich, complex, and varied.

The primary task of a philosophy of religion is to ascertain and exhibit the nature of religion. Now, a general theory of religion is the natural introduction to all special religious studies and theological sciences, and yet can itself only be brought to perfection through the advancement of these studies and sciences. For example, we can only adequately understand the nature of religion through study of the history of religion, and yet we cannot trace the history of religion at all unless we know generally what religion is. Again, in such works on Christian dogmatics as those of Schenkel, Kahnis, Biedermann, and Lipsius, we find a considerable place assigned to an investigation into the general nature of religion. The investigation is manifestly not there strictly appropriate; its true position can only be in another and wider science. At the same time, it is undoubtedly a necessary antecedent to the investigations of Christian dogmatics, from the very fact that Christianity is a religion. On the other hand, Christianity is not only a religion, but a religion which claims to be the perfect or absolute religion; and, clearly, if the claim be well founded, the complete nature of religion can only be understood through that full knowledge of Christianity which Christian science may be expected to give.

From the very nature of religion the science or philosophy which treats of it as a whole must obviously be most comprehensive. Religion is a relation between a worshipping subject and a worshipped object. It implies both distinction and unity. Were there no distinction between the subject and the object there would be no religion, whether the self-identical unity were named God or man. Were there only distinction between them—were God and man absolutely separate from and indifferent to each other,—religion must be in this case also impossible. Religion thus supposes two factors, which are different yet related, so far distinct and so far akin; and our views of religion must depend on our views of these two factors. It involves still more. God does not act on man by the direct manifestation of His absolute essence, nor does man know God by immediate vision. Take away the physical and moral worlds and the written word and the Incarnate Word of God—suppose, that is to say, both general and special revelation removed—and an impassable chasm will separate man from God and all religion be destroyed. The revelation in nature and the revelation through particular inspiration and intervention, however, bridge over this chasm, and consequently religion is everywhere found existing in some form. But even revelation would be useless if man had not faculties to apprehend it and to avail himself of it. The communion of man with God supposes powers of communion in man as well as in God. It can only be realized through religious faculties and processes which can be analyzed and which have laws of exercise and evolution that can be traced. Further, religion has a history which shows how man has interpreted or misinterpreted the revelations made to him, what forms religion has assumed in various lands and ages, and how these forms—the religions of the world—have arisen and spread, developed and decayed, influenced one another and affected morality, civilization, and general history. Thus religion, from its very nature or idea, requires us to treat—(1) of the object of religion (God), (2) of the subject in religion (man), and (3) of the media and process of religion,—or, in other words, (*a*) of the modes of Divine manifestation, (*b*) of the powers of human apprehension of the Divine, and (*c*) of religion itself as a kind of psychical life. All the special theological sciences deal with some of these themes, or some portion or portions of some of these themes, in certain aspects, but the philosophy or general science of religion deals with them all in their entirety and organic connectedness, the form appropriate to philosophy—to science which comprehends and thereby transcends special sciences.

For the philosophy of religion, as the highest discipline of theology, the most natural order to be followed in the treatment of its themes is probably that which has been indicated. It is the order which has been most commonly adopted in treatises that aimed at systematic completeness. God, man, God's manifestation of Himself to man, man's experience of God, and the development of religions,—these are the topics, and such is, in the main, the order of their discussion, usually found in philosophies of religion properly so called. This is, however, because the philosophy of religion as a distinct discipline presupposes the results of the several special theological sciences. Theology ends as it begins, in unity; but the unity in which it ends is very different from that in which it begins. It begins with the confused unity of common knowledge, the complex and undifferentiated germ of the theological sciences; it ends with the unity of the clearest and deepest insight, in which all distinctions are at once recognized and reconciled. This last is the unity of that ultimate stage of theological knowledge which can alone claim to be philosophical as distinguished from scientific; and it can only be reached by those who have attained to an adequate mastery of all the sciences conversant with religion. The philosophical student of the whole must have studied scientifically its parts, know what is to be known about them, and make use of his knowledge in his own proper labors. The student of the parts needs to know only in a general way what religion is, and must follow in his studies an order of procedure determined by his lack or limitation of knowledge. The course by which the mind traverses the partial and special sciences of religion and rises to a philosophy of religion cannot be the same as that through which it unfolds a philosophy of religion itself, exhibits and confirms a religious theory of the universe, and harmonizes and elucidates all results of theological research and all varieties of religious phenomena.

The philosophy of religion is itself, of course, special in relation to philosophy, of which it is only a department. And there may even be a special kind or form of the philosophy of religion, if that kind or form be general enough to include a natural group of theological sciences and to have regard to their collective effects. A special religion may be so significant, so important, and the subject of so many theological disciplines as to render indispensable the division alike of the philosophy and of the sciences of religion into general and special. Christianity, as the most perfect form of religion, the fullest revelation of spiritual truth, the source and theme of a large group of sciences, is such a religion. Hence there may be, and should be, not only a philosophy of religion but a philosophy of Christianity,—not only a generically religious but a specifically Christian theory of the universe. If the claims of Christianity be warranted, if in it religion and revelation were consummated, the philosophy of religion can only reach a satisfactory conclusion when it has passed into a philosophy of Christianity, or, in other words, attained such a comprehension of existence and life in relation to the person and work of Christ as is possible to the human spirit. The philosophy of Christianity must obviously be connected with all Christian disciplines in the same manner as the philosophy of religion is with all other theological disciplines.

---

[1] The best account of the history of theological encyclopædia is that given by Räbiger in his *Theologik oder Encyclopädie der Theologie* (1880), of which there is an English translation, with notes which considerably increase the value of the work, by the Rev. J. Macpherson (2 vols., 1884). The account in Zöckler's *Handbuch der theol. Wissenschaften*, i. 87-111 (1885), is also good. The fullest account of the history of attempts to classify the sciences is that of the present writer in *Presby. Rev.* for July, 1885, and July, 1886. The following may be specified as among the most useful of theological encyclopædias: Schleiermacher's *Kurze Darstellung des theol. Studiums*, 1st ed., 1810, 2d ed., 1830; Staudenmaier's *Encyclopädie der theol. Wissenschaften*, etc., 1834; Hagenbach's *Encyclopädie u. Methodologie der theol. Wissenschaften*, 10th ed., 1880; Crook's and Hurst's *Encyclopædia and Methodology, on the Basis of Hagenbach*, New York, 1884; Doede's *Encyclopedie der Christelijke Theologie*, 2d ed., 1883; Lange's *Grundriss der theol. Encyclopädie*, 1877; Von Hofmann's *Encyclopädie der Theologie*, 1879; Rothe's *Theologische Encyclopädie*, 1880; Drummond's *Introduction to the Study of Theology;* and Cave's *Introduction to Theology*, 1886. See also the article of Willibald Grimm, "Zur theol. Encyclopädie," in *Ztschr. f. wissensch. Theol.*, 1882, i.; and Gretillat's *Exposé de Théologie Systématique*, vol. i., "Propédeutique," 1885.

History of philosophy of religion.

The history of the philosophy of religion has, of course, been closely conjoined with the histories both of theology and of philosophy, and influenced by all the causes which have affected them. In the wide sense of religious reflection it is as old as either philosophy or theology. As a distinct department of philosophy, and the highest and most comprehensive theological science, it is of comparatively recent origin, and, indeed, younger than many a living individual; but even in this latter sense the whole histories both of philosophy and of theology have been needed as the preparation and foundation for it. It could only appear in its alone adequate form when both philosophy and theology were highly developed, when both had freed themselves from the yoke of all authority save that of truth and reason, when both had discovered their appropriate methods, when they could so combine as to do no violence to the proper nature of either—a kind of combination most difficult to accomplish. But this, as might easily be shown, was not before philosophy and theology became at once critical and speculative, or, in other words, before that great revolution of thought with which the names of Kant, Hegel, and Schleiermacher are so gloriously associated. Only in the present century have philosophy and theology reached the stage in which they can unite and produce a philosophy of religion. And within the century many philosophies of religion have made their appearance, especially in Germany. Indeed, all the more eminent philosophers of Germany have fully recognized that a philosophy of religion is a most essential department of philosophy. That not a few of the so-called philosophies of religion produced have been very defective and erroneous is only what was to be expected. The worth of a man's philosophy of religion cannot be greater than the worth of his philosophy and theology in general. It is impossible that the philosophy of religion of an Hegelian and a Neokantist can accord, very possible that both may be far remote from the truth. If empiricism, positivism, or materialism be true philosophy, or if authority be the foundation of religion and the standard of theology, a philosophy of religion must be illegitimate and superfluous. When religion is assumed to consist merely of beliefs, emotions, and actions which have no objective grounds, no real and rational basis, its development can only be an object of history and of psychological analysis, and there can be no philosophy of religion, but simply a science of religions, which, seeing that it deals entirely with certain forms of mental disease and delusion, must be deemed merely a department of mental pathology. A philosophy essentially religious must combine with a theology essentially rational in order to yield what deserves to be called a philosophy of religion. If religion be the living apprehension and enjoyment of the truth which philosophy has for its mission to seek to comprehend, then, but only then, must a philosophy of religion be necessary alike to philosophy and religion.[1]

Special theological sciences:

We now pass to special theological disciplines which can at the utmost merely become sciences as distinguished from philosophy. They all deal with religion, each of them treating of some particular portion or aspect of it; and the order and mode in which they do so determines their relations to one another and the order of their succession. If we would rise, for example, through study of the parts or phases of religion in a sure and natural manner to a knowledge of it as a whole, we must necessarily begin with what of it is nearest and most accessible to us. But what is so is its history.

Historical;

In its historical manifestation it is a phenomenon which no one can refuse to acknowledge. The history itself, however, is not only a most extensive but a very complex phenomenon. It is external and internal, corporeal and spiritual, a history of outward events and actions, institutions and rites, and also of ideas, convictions and affections. What is external is nearer and more accessible to us than what is internal, and it is through the former that we must penetrate into the latter. They cannot be quite separated, for the external is only intelligible through the internal, and the internal only attainable and verifiable through the external; but they can be so far differentiated, and there is a history mainly of what is external in religion and another mainly of what is internal. The ordinary history of religion is mainly concerned with tracing the growth of religion in its most apparent form and institutional character. It may be divided into three great sections—the ethnic, Biblical, and ecclesiastical,—the history of the heathen religions, the history of the Jewish religion and of the rise of Christianity, and the history of the Christian church. Whether history in this form, even when studied in the most accurate and thorough manner, should be called science may be doubted, as it is simply occupied with the discovery and description of the particular and concrete. It is not usual so to designate it in any of its sections. The history of religious beliefs and ideas may be as purely and properly history as that of external institutions and transactions. It deals, however, not only with what is internal and spiritual but also with what is abstract and general, and hence it is at least more akin to science than is common history, and its sections are often called sciences. These sections are three in number, and correspond to the sections of the ordinary history. They are known as comparative theology, Biblical theology, and the history of Christian doctrine. To the last of these, symbolics may fairly claim to be a necessary supplement. They are quite distinct from conceivably attainable knowledge of the laws of religious history, such as might be with strict propriety designated science of religious history, a department of science of history. Of historical science in this last sense there is as yet extremely little.

Psychological;

Religion is a spiritual process, and its history continuously implies the affections and operations of mind. The historical treatment of religion, therefore, necessarily leads to its psychological treatment. The history alike of religious events and actions and of religious ideas and beliefs can only be explained through a knowledge of the religious powers and processes, *i.e.*, of the psychological factors and states which condition and determine its development. The psychological study of religion, although it has been greatly neglected, should reach over a very large department of theology. The department may be distributed into three disciplines—the general, comparative, and special psychology of religion. The first should treat of the general religious nature of man; the second should discover and compare the psychical peculiarities to be found in the various religions; and the third should exhibit elaborately the psychology of a particular religion, as, *e.g.*, Biblical and Christian psychology.

Apologetic;

The historical and psychological sciences of religion deal with religion merely as an historical and psychological phenomenon. They do not imply its truth, and can be cultivated by those who regard it as a delusion equally with those who acknowledge it to be a certainty. It is the office of apologetics to determine whether or not it is true and how far it is true. If it end not in a negative result, in agnosticism or atheism, it must prove that God reveals himself to man, and that man apprehends God. In other words, apologetics treats of the media of revelation—alike the objective and subjective, Divine and human media—and so is the science, on the one hand, of revelation, and, on the other hand, of religious certitude. It is divisible into general and special, or, in equivalent terms, into theological and Christian apologetics,—the former being the scientific exhibition of the grounds of natural religion, and the latter of the grounds of the Christian religion. They are sometimes combined, inasmuch as both are needed in order to establish the truth of Christianity. In Germany it has become not uncommon to fuse them into one under the name of fundamental theology, described as the science which treats of the foundation of Christianity. And, undoubtedly, it is not only expedient but even necessary to treat of both as introductory and preparatory to the construction of Christian science. But the distinction between them must not, therefore, be forgotten or ignored. Theological apologetics might be irresistible although Christian apologetics were futile. Theological apologetics derives its validity from its relation to natural theology, which has an absolute value of its own, wholly independent of any other science, of Christianity, or of anything else. The alliance of theological and of Christian apologetics is perfectly legitimate; the attempt to combine them into a single science, into a single homogeneous discipline, is decidedly the reverse.

---

[1] There is a laborious and impartial history of the philosophy of religion by Bernhard Punjer, *Geschichte der christlichen Religionsphilosophie*, 2 vols., 1880-83. Of this valuable work an English translation is soon to appear. Some chapters of the history have been ably written by O. Pfleiderer in his *Religionsphilosophie auf geschichtlicher Grundlage*, 1884, a first volume of a translation of which has been published. For a list of works on the philosophy of religion the last edition of Hagenbach may be consulted. Here the following only can be mentioned: Hegel, *Philosophie der Religion*, 2 vols., 1832; Krause, *Die absolute Religionsphilosophie*, 2 vols., 1835; Ohlert, *Religionsphilosophie in ihrer Uebereinstimmung mit Vernunft, Geschichte, und Offenbarung*, 1835; Billroth, *Vorlesungen über Religionsphilosophie*, 1837; Steffens, *Christliche Religionsphilosophie*, 2 vols., 1839; Taute, *Religionsphilosophie, vom Standpunkte der Philosophie Herbarts*, 2 parts, 1840-52; Rothe, *Theologische Ethik*, 3 vols., 1845; Weisse, *Philosophische Dogmatik oder Philosophie des Christenthums*, 3 vols., 1855-62; Apelt, *Religionsphilosophie*, 1860; Stöckl, *Lehrbuch der Religionsphilosophie*, 2d ed., 1878; Lotze, *Grundzüge der Religionsphilosophie*, 1882; Von Hartmann, *Religion des Geistes*, 1883; Teichmüller, *Religionsphilosophie*, 1886; Morell, *Philosophy of Religion*, 1849; Caird, *Introduction to the Philosophy of Religion*, 1876; Morris, *Philosophy and Christianity*, 1883.

Systematic.

The highest stage of theological science is the methodical education and exhibition of the truth involved in religion, either as contents of faith or elements of life. When conversant with the faith it is dogmatics, when with the life ethics; but, of course, here again distinction is not to be confounded with separation. True faith is living faith, and true life is the life of faith. Dogmatics and ethics are so intimately related that it is not surprising that they should have been long left undifferentiated, or that a few eminent theologians should still deny that they can be properly treated apart. Theology at this stage is commonly designated systematic, although the term is not a good one, and others, little if any better perhaps, as didactic, theoretical, positive, thetic, etc., have been suggested as substitutes. Systematic theology, like historical, psychological, and apologetic theology, is divisible into general and special, the former including natural theology and theological ethics, and the latter Christian dogmatics and Christian ethics. The identification, so common in Britain, of systematic theology with Christian dogmatics is, of course, solely due to the survival among us of prescientific thought and language in theology.

The historical and psychological sciences of religion may be conjoined under the designation of empirical, or phenomenological, or historical (in the widest sense); the apologetic and systematic sciences under that of didactic, thetic, speculative, or systematic (in a loose sense). This twofold division of them is the one generally adopted. And as it rests on an obvious and important distinction it is fully entitled to acceptance, provided it be so received as not to hide or extrude the fourfold division founded on the real moments or stages of the process of theological investigation.

Exegetical and practical theology.

There are a considerable number of disciplines not included in the divisions indicated, yet for which the theological encyclopædist is bound to find appropriate places. The best classificaton of these is into exegetical and practical. So-called exegetical theology, however, is in all its departments simply instrumental and introductory to historical theology; and practical theology is in all its departments concerned with the use and application of religious knowledge, not with its acquisition and advancement. The former is not directly occupied with religion but with the records and documents from which its history must be ascertained; the latter is art and not science.

Considering theology, then, only as science directly engaged on religion, the following are the sciences which belong to general theology: (1) the history of religions; (2) comparative theology; (3) psychology of religion; (4) theological apologetics; (5) natural theology; and (6) theological ethics. Those of Christian theology are—(1) Biblical history; (2) ecclesiastical history; (3) Biblical theology; (4) history of Christian doctrine; (5) symbolics; (6) Biblical and Christian psychology; (7) Christian apologetics; (8) Christian dogmatics; and (9) Christian ethics. The remainder of this article will be devoted to a brief indication of the nature of such of the above studies as have not already been treated of in separate articles.

History of religions and comparative theology.

The history of religions and comparative theology differ from each other as sacred history and Biblical theology or ecclesiastical history and the history of Christian doctrines differ. That they should rarely be distinguished proves only that the ethnic sacred books have not yet been so closely studied as the Bible, and that the histories of the great ethnic religions are not yet so well known as the history of Christianity. As regards both the history of religions and comparative theology, see RELIGIONS.

Psychology of religion.

The general psychology of religion should analyze the religious nature of man and trace the laws of its development. It has to ascertain the principles which guide reason in the search after God; to determine what subjective religion is, what elements it involves, and through what stages it may pass; and to show how the understanding and imagination, the emotions and affections, the qualities and energies of will, operate in religion and influence its character. While general psychology of religion thus treats man as framed and fitted for religion, the comparative psychology of religion treats of the psychological composition and peculiarities of the various concrete and collective manifestations of religion. It is related to the general psychology of religion as comparative psychology to general psychology. It must concern itself with the religions of the rudest peoples. It has to explain what is psychologically distinctive of fetichism, animal worship, naturalistic religions like the Vedic, anthropomorphic polytheisms like those of Greece and Rome, and pantheisms like Brahmanism and Buddhism. For example, in each of these forms of religion imagination works differently, and the comparative psychology of religion should give a complete view of the operations of imagination in the formation of the religions of humanity. So as regards all the chief intellectual principles and all the chief sentiments.

The psychological study of religion was not, as is often said, begun by Kant. Hume—in virtue of his *Natural History of Religion*, with its clear recognition of the distinction between the *causes* and the *reasons* of religion—is much more entitled to be considered initiator in this department, but even his claim may be contested. The department is one of which there is as yet no general survey, and of which many portions have been entirely overlooked. What the ordinary psychologists—*e.g.*, Bain, Sully, Thompson, Rabier, Fortlage, Strümpell, Volkmann, Wundt—say regarding it is very vague and meagre. The only two points which have been closely investigated are those as to the nature of religious cognition and the essence of religion, and as to both speculation has been frequently allowed to disturb and pervert psychological analysis. For some of the later literature on these points, see notes on article THEISM. Neither the general nor the comparative psychology of religion as yet exists in a separate and appropriate form. What religious psychology there is will be found chiefly in the writings of anthropologists like Bastian and Tylor, of comparative philologists like Max Müller and Steinthal, of philosophers like Spencer and Renouvier, of theologians of the school of Schleiermacher, and, above all, in the histories of religions and the philosophies of religion.[1]

Theological apologetics.

Theological apologetics is not to be confounded with natural theology, from which it is as distinct as Christian apologetics is from Christian dogmatics. It lays a foundation for natural theology, inasmuch as it vindicates religion by showing that it rests on objective spiritual truth. It presupposes a knowledge of religion as an historical and psychological phenomenon, but none of natural theology, which it, of course, leaves as a science to establish its own doctrines. It has the following tasks to perform. (1) To show that man is capable of apprehending the divine. This requires the refutation of agnosticism and the vindication of the principles implied in religious knowledge and certitude.[2] (2) To prove the reality of a revelation of the Divine in physical nature, mind, and history. The results of the various sciences will thereby be shown to be data of theology. It requires the refutation of atheism, materialism, positivism, and secularism, and of all principles which logically involve these systems. (3) To exhibit the reasons for the true conception of the Divine, and to expose the arguments employed in favor of false conceptions. The defence of theism, for example, must be accompanied by proof of the erroneousness and insufficiency of the polytheistic, dualistic, deistic, and pantheistic hypotheses. (4) To adduce whatever evidence may be contained in general revelation for the immortality of the soul and a future state of rewards and punishments.

---

[1] Alliott's *Psychology and Theology*, Newman Smyth's *Religious Feeling*, Brinton's *Religious Sentiment*, Happel's *Anlage des Menschen zur Religion*, Ulrici's *Gott und Mensch*, and Lesbazeille's "Bases Psychologiques de la Religion" (two articles in *Rev. Phil.*, vol. xxi., 1886) may be specially mentioned.

[2] For the literature on agnosticism, see above, p. 255, note 2.

Natural theology.

Natural theology is the systematic exposition of the truths in natural or general revelation. Its data are the facts and laws of nature, as ascertained by physical, mental, and historical science. Its inductions and inferences relate to God, men, and their relationship. Its appearance as a distinct science may be dated from the publication of Raymond de Sebonde's *Theologia Naturalis* in 1436, although portions of it had been admirably presented by ancient philosophers, *e.g.*, Socrates, Plato, Aristotle, and Cicero. It flourished with extraordinary vigor in the latter half of the 17th and throughout the 18th century. It should endeavor to perform the following tasks. (1) To describe the nature, character, and attributes of God, so far as they are disclosed by the material world, mind, and history. (2) To treat of God in relation to the world and man, and of the world and man in relation to God, under which head all questions as to creation, providence, theodicée, optimism and pessimism, education of the human race, etc., will fall to be discussed from the standpoint of general revelation. (3) To determine, so far as can be done from general revelation, what man may reasonably hope for as to deliverance from sin and its consequences, and what he may reasonably believe as to the conditions of existence in a future world. As to this third point the view is prevalent that the light of nature discloses nothing regarding man's salvation or future destiny. But does this view not arise from overlooking that the kingdom of God is within, and from falsely supposing that salvation is entrance into an external, non-spiritual heaven on conditions which, being in themselves non-natural, cannot be naturally known? The heathen nations have certainly not supposed nature to be wholly silent and dark on the subject. In every developed ethnic religion there is a soteriology and eschatology as well as a theology. Man is nowhere necessarily without hope any more than without God in the world.[1]

Theological ethics.

Theological ethics differs from natural theology in that it seeks in nature, viewed as a Divine revelation, laws of spiritual life, not merely religious doctrines. Its place is between moral philosophy and Christian ethics. It is unmistakably distinct from both, and may be more plausibly included in natural theology than in either. It should endeavor (1) to determine how religion and morality are distinct and how connected; (2) to ascertain how morality has been affected and modified by the various positive ethnic religions and the various religious but non-Christian philosophies; (3) to exhibit how the character of God, as delineated by natural theology, stands related to the moral law, the moral life, and the chief ethical end or supreme good of man; (4) to describe the duties which the light of nature shows that man owes directly to God; and (5) to trace how piety to God must influence personal and social virtue. Unlike moral philosophy and Christian ethics, it can hardly be said to have been yet treated as a separate discipline and presented as a whole. Daub and Marheineke have, indeed, written works nominally on *Theological Morals*, and Rothe and Von Hofmann on *Theological Ethics*, but in all these works it is really Christian ethics which is exhibited to us under certain speculative lights. There is, however, a very extensive literature relating to particular problems and portions of theological ethics. Thus what has been just indicated as problem first—that as to the relation of religion and morality—has been long much discussed.[2] The second problem demands wide and close historical research; it has been touched at a multitude of points, but only touched. With the third problem, or rather group of problems, almost all systems of Christian ethics have to some extent dealt; and with the fourth and fifth problems almost all systems of moral philosophy.

Biblical and church history.

We now pass to Christian theology. Its historical section includes, besides the histories of Israel and the church (as to which see ISRAEL and CHURCH HISTORY), Biblical theology, the history of Christian doctrine, and Christian symbolics.

Biblical theology.

All hermeneutical studies are auxiliary to exegesis, and all Biblical exegesis leads up to that comprehensive and connected view of the development of Biblical ideas which it is the aim of Biblical theology to set forth. Biblical theology is not to be understood as meaning a theology founded on the Bible—Christian dogmatics under another name. It does not assume that the Bible is either a source or standard of truth. It does not set forth the ideas which it exhibits as true in themselves, but only as truly in the Bible. It seeks no other truth than truth of exposition. It aims at doing no more than giving a true account of what are the religious ideas in the Bible, of how they are related as set forth in the Bible, and of what their history has been throughout the Biblical period. Its sole business is critically to ascertain and truthfully to exhibit what Scripture teaches, what each writer, even, of Scripture teaches, in a purely objective, organic, historical manner. It cannot possibly be confounded with Christian dogmatics by any one who has the slightest notion of what it is, although the latter must in great part rest on it and derive most of its materials from it. It is the ultimate direct result and the most comprehensive and perfect product of Biblical exegesis, and related to the history of religious ideas as a part to the whole in which it is included, comparative theology preceding and the history of Christian doctrine following it. It divides into theology of the Old Testament and theology of the New Testament; and its method is one appropriate to an historical discipline, and, therefore, chronological, genetic, analytic, and synthetic. It is a comparatively recently constituted department of theological science, both Catholic and Protestant divines having made for ages the enormous mistake of studying Scripture—so far as their interest therein was theoretical and not practical—primarily in order to find proof of the doctrines contained in their creeds and confessions. They failed to apprehend and appreciate the seemingly very simple thought that Scripture should be studied in the first instance with a single eye to find out what was really in it, and that to this end the study of it should be strictly and purely exegetical and historical. J. Ph. Gabler, in his thesis *De Justo Discrimine Theologiæ Biblicæ et Dogmaticæ*, published in 1787, was the first clearly to show the true character of Biblical theology as an essentially historical study. Since then it has been cultivated with great zeal by a host of able laborers.[3]

History of Christian doctrine.

The history of Christian doctrine only began to be treated as a separate theological discipline in the latter part of the 18th century. Previously it was dealt with as an appendix to dogmatics or as a part of church history. It is not an appendix to dogmatics, but it includes its history and contributes to lay a foundation for it. No doctrine can be either correctly understood or rightly developed where there is ignorance of its history. The history of Christian doctrine is a part of the history of Christianity, namely, the history of Christian beliefs, as distinguished, on the one hand, from the history of Christian life and practice, and, on the other hand, from the outward history of the church. It is a part also of the history of religious thought, and of the history of thought in general, and therefore closely connected with the history of philosophy. Its development must be admitted to be ruled by the general laws of the intellectual history of man. It may be taken, however, in a wider or narrower sense,—in the former being the history of Christian thought and belief as such, and in the latter the history only of dogmas strictly so called, *i.e.*, of doctrines formulated and promulgated by ecclesiastical authority, and accepted either by the whole church or by large divisions of the church. There ought perhaps to be a history of doctrines in both senses. One in the former sense has only been undertaken recently by Harnack. The method of the history of Christian doctrine must be strictly historical, and at the same time both analytic and synthetic, seeing that both the history of the separate doctrines and the general and connected evolution of the doctrines require to be traced. Its periods will coincide with those of church history, but they ought to be determined from direct examination of the development of the doctrines. It is incorrect, therefore, to represent the discipline as having its general distribution into periods given it by church history.[1]

---

[1] For the literature of apologetics (theological and Christian), see Bedford's *Christian Plea against Modern Unbelief*, pp. 497–533. For a list of the best works on theological apologetics and natural theology, see Cave's *Introduction to Theology*, pp. 149–161. Indications as to the history and literature of many particular questions and portions of both disciplines are given in the notes to Flint's *Theism* and *Antitheistic Theories*. One of the best sketches of the history of natural theology is that in Zöckler's *Theologia Naturalis*. Here it may be sufficient to mention the following works: Butler's *Analogy*; Paley's *Natural Theology*; Chalmers's *Natural Theology*; the *Bridgewater Treatises*; Thompson's *Theism*; Tulloch's *Theism*; M'Cosh's *Method of the Divine Government*; Ulrici's *Gott und die Natur*; Jules Simon's *Natural Religion* (Eng. tr.); Janet's *Final Causes* (Eng. tr.); Caro's *Idée de Dieu*, 5th ed.; Gratry's *Connaissance de Dieu*, 7th ed.; and Margerie's *Theodicée*, 3d ed.

[2] The following references may be given: the last chapter of Janet's *La Morale*; the first three chapters in Caro's *Morale Sociale*; many articles and reviews in Renouvier's *Critique Philosophique*; Martensen's *Christian Ethics*, §§ 5–14; Pfleiderer's *Moral und Religion*; Bradley's *Ethical Studies*, pp. 279–305; and Caird's *Introd. to Phil. of Rel.*, ch. ix

[3] For the history of Biblical theology, see Brigg's *Biblical Study*: for the literature Cave, Hagenbach, Räbiger, or Zöckler; for a reference to some of the best works, see THEISM, *supra*, p. 258, notes 2 and 3.

Symbolics.

Symbolics is the historico-comparative study of the dogmatic systems of the various Christian communions, as expressed and involved in their symbolical documents. It treats of the origin, history, and contents, and relations of difference and agreement, of the various creeds and confessions of Christendom. It was preceded by "polemics" and "controversial theology"—pre-scientific and anti-scientific kinds of theology. The older so-called systematic theologies and systems of divinity consisted largely of symbolical matter treated in an unscientific and ungenerous spirit. Christian dogmatics will never be properly purified until Christian symbolics receives intelligent and due recognition, and has relegated to it the subjects which properly belong to it. Christian symbolics may be said to have made its appearance as a separate scientific discipline with Marheineke's *Symbolik*, published in 1810. The chief reason why it appeared thus late was the difficulty of exercising in this sphere the impartiality of the true historical spirit. The arrangement of its material is determined partly by the order of succession in which the churches appeared in history and partly by the historical importance of the different churches. "In some treatises on symbolics the symbolical system of doctrine of each church is treated separately, while in others the several doctrines of the various churches are compared together. Each of these methods has its advantages and disadvantages. Their combination is requisite."[2]

Biblical psychology.

The psychology of Christianity may be held to include Biblical psychology and the psychology of the Christian life. It must be admitted, however, that the right of the former to a place among psychological sciences is doubtful. It is universally admitted that it ought to present what is taught in the Bible as to the origin, nature, faculties, states, processes, and future development of the human spirit, and also elicit the conceptions implied and presupposed in the Biblical statements on these points. But if it do this in a merely historical manner, and do nothing beyond this, it must manifestly be regarded as simply a section of Biblical theology. To be entitled to be considered a separate psychologico-theological discipline it must at least also discuss the questions as to the truth of the ideas relative to the human spirit expressed and implied in Scripture, as to their accordance with the facts of mind, and their relationship to the conclusions of ordinary scientific psychology; and even then it may be held to be rather the result of a peculiar combination of history, apologetics, and psychology than a properly psychological discipline. However this may be, the study is an exceedingly interesting one. It has had a lengthened history, for in almost every generation since the 2d century treatises on some of its subjects have appeared. It was inaugurated by Melito and Tertullian, obtained in the 17th and 18th centuries distinct recognition under the designation of "psychologia sacra" or "psychologia e sacris literis collecta," and acquired fresh life and scientific form from the publication of Beck's *Umriss der biblischen Seelenlehre* in 1843.[3]

Christian psychology.

The psychology of the Christian life is a much more comprehensive discipline than Biblical psychology, and one as to the precise place and scope of which no dubiety need be felt. Its work is to elucidate all the distinctively Christian phenomena both of the individual and of the collective life. As to the former it should evolve a theory of personal Christian experience, normal and abnormal, in its purity and in its perversions. As to the latter, it should explain the spiritual experience of Christian society—the development of Christian piety—in different ages, countries, and churches. For the accomplishment of the former task it will find help and material in religious poetry, religious biography and autobiography, and all other expressions and records of personal Christian experience; and for the accomplishment of the latter in all the sources and contents of church history, although these must be used in accordance with the psychological purpose in view. Christian psychology thus understood is a department of theology still to form. And the difficulties in the way of its formation must be allowed to be very great. They will only be overcome by men in whom profound psychological science and insight are combined with a rare susceptibility and richness of spiritual life.

For Christian apologetics, see APOLOGETICS. For Christian dogmatics, see DOGMATICS.

Christian ethics.

Christian dogmatics and Christian ethics are the two disciplines included in Christian systematic theology. They ought to be separated and cultivated apart, and yet must be recognized to be closely connected, and each the necessary complement of the other. The former sees in Christ the truth and the way thereto; the latter sees in Him the life and the way thereto. Christian ethics is much the more recent discipline of the two, and it has not yet attained the same definiteness and homogeneousness. Alike as to method and distribution there is greater indecision and confusion. Among its earlier cultivators were Danæus, Calixtus, Perkins, Ames, Colville, Mosheim, Crusius, Ständlin, and Von Ammon. Schleiermacher may justly be regarded as the founder of modern Christian ethics. His superiority to his predecessors was due chiefly to his profounder apprehension of the nature of the problems of philosophical ethics, and to his comprehensive and spiritual conception of the kingdom of God as the highest good, pervasive and regulative of every sphere of human life, industry and art, science and philosophy, family, church and state. The following may be given as a scheme of Christian ethics. I. Determination of the nature, limit, and method of the science, and of its relations to other disciplines, and especially to those which are ethical and theological. II. Presuppositions of the science: these are—(1) the ethical idea of God as revealed in nature and in Christ; (2) man as a moral being and in his relation to the law and revelation of God; (3) creation and providence as ethical systems; and (4) the kingdom of God in itself, in relation to creation and providence, and as the goal of moral life. III. The fundamental conceptions of the science: these are—(1) the Christian ethical law; (2) the Christian conscience; (3) the Christian ethical ideal; and (4) Christian virtue. IV. The reign of sin in the individual and society viewed in the light of Christianity. V. The origin and progress of the kingdom of God in the individual soul, and its manifestation in the virtues and graces of the Christian character. VI. The realization of the kingdom of God in the various spheres of society—the family, the church, the nation.[4] (R. F.)

THEOPHILUS. Nicholas Alemanni, in his notes to the first edition of the *Anecdota* of Procopius (see PROCOPIUS), published in 1623, repeatedly quotes a Life of Justinian, which he attributes to "Theophilus Abbas, præceptor Justiniani," but without telling us where he found this Life or who Theophilus was. Subsequent writers have continued to quote Theophilus from Alemanni's notes for the facts ascribed to him in those notes, and, among others, for the name Upravda, said to have been the original name of Justinian, and other proper names of members of the family of that emperor. Mr. Bryce has, since the article JUSTINIAN was published, discovered in the Barberini library at Rome what appears to be the MS. of the so-called Life of Justinian used by Alemanni. It is in Latin, and purports to be an extract made by

---

[1] Among the best general histories of Christian doctrine are those of Neander, Gieseler, Hagenbach, Baur, Nitzsch, Thomasius, Harnack, Haag, Shedd, and Sheldon. There is a multitudinous literature relating to doctrine in particular periods and to particular doctrines.

[2] See Lumby's *History of the Creeds*, 1873; Schaff's *Creeds of Christendom*, 3 vols., 4th ed., 1884; Winer's *Confessions of Christendom;* and the *Symbolics* of Möhler, Köllner, Guericke, Oehler, Hofmann, etc.

[3] The following are among the most useful books for the student of Biblical psychology: Beck's *Outlines of Biblical Psychology* (Eng. tr.); Delitzsch's *System of Biblical Psychology;* Heard's *Tripartite Nature of Man;* Laidlaw's *Bible Doctrine of Man;* and Dickson's *Baird Lecture for* 1883.

[4] The history of Christian ethics has been written by Wuttke, *Christian Ethics*, vol. i., but much better by Gass, *Gesch. der christl. Ethik*, 2 vols., and by Ziegler, *Gesch. d. christ. Eth.*, 2 vols. Bestmann has written two volumes of a *Gesch. d. christl. Sitte.* Among well-known treatises on Christian ethics are those of De Wette, Schleiermacher, Hirscher, Harless, Rothe, Wuttke, Sartorius, Martensen, Oettingen, Lange, Hofmann, Frank, and Dorner. Those of Wuttke, Sartorius (*Doctrine of Holy Love*), Harless, and Martensen have been translated into English. German literature is extremely rich, while French and English literatures are miserably poor, in this department. Wardlaw's *Christian Ethics* may be mentioned, but merely because it is English.

Ivan Tomco Marnavich, a Croatian ecclesiastic (1573–1639), from a Life of Justinian by a certain Bogomil (Græce *Theophilus*), who is alleged to have been the instructor of Justinian, and abbot of St. Alexander at Prisrend (in Macedonia), and afterwards bishop of Sardica (now Sofia, in Bulgaria), the original of which Life, in Slavonic, is stated in the Barberini MS. to exist in the Slavonic monastery of Basilian monks on Mount Athos. No such Slavonic MS. (so far as is known) has ever been discovered in Athos or elsewhere; no Slavonic MS. of the age of Justinian could possibly exist; and the contents of the Latin extract preserved at Rome are of so legendary a character as to throw the greatest doubt on the facts cited from Theophilus by Alemanni, including the name Upravda above referred to, and the Slavonic origin of Justinian. It seems doubtful whether this Theophilus Abbas, whom the Roman MS. identifies with a certain Domnio, bishop of Sardica in 517 (see Marcellinus Comes, *Chronicon*, ad ann. 517), ever existed at all. Mr. Bryce has printed this Roman MS., with his observations thereon, in the *Archivio Storico* of the R. Società Romana di Storia Patria, 1887.

THEOPHRASTUS, the successor of Aristotle in the Peripatetic school, was a native of Eresus, in Lesbos. The date of his birth is a matter of inference, and has been fixed between 373 and 368 B.C. It is said that his original name was Tyrtamus, and that the name Theophrastus was given him by Aristotle on account of his eloquence, but this story is quite as likely to be an afterthought suggested by the name at a later date. After receiving his first introduction to philosophy in Lesbos from one Leucippus or Alcippus, he proceeded to Athens, and became a member of the Platonic circle. After Plato's death he attached himself to Aristotle, and in all probability accompanied him to Stagira. The intimate friendship of Theophrastus with Callisthenes, the fellow-pupil of Alexander the Great, the mention made in his will of an estate belonging to him at Stagira, and the repeated notices of the town and its museum in the *History of Plants* are facts which point to this conclusion. Aristotle's affectionate confidence in his pupil and friend is proved by his making Theophrastus guardian of his children in his will, and designating him as his philosophic successor at the Lyceum on his own removal to Chalcis. Eudemus of Rhodes was not without claims to this position, but the master, according to the well-known story, delicately indicated his preference by the remark that the wines of Lesbos and Rhodes were both excellent, but the Lesbian was the sweeter. Aristotle also bequeathed to Theophrastus his library and the originals of his own works. Theophrastus presided over the Peripatetic school for thirty-five years, and died in 288 B.C. Under his guidance the school flourished greatly in point of numbers, and at his death he bequeathed to it his garden with house and colonnades as a permanent seat of instruction. His popularity was also shown in the regard paid to him by Cassander and Ptolemy and by the complete failure of a charge of impiety brought against him. He was honored with a public funeral, in which the whole people took part.

Theophrastus's philosophical relation to Aristotle and his place in the development of Peripatetic doctrine have been sketched under the head PERIPATETICS It remains to say a few words about his works. From the lists of the ancients it appears that the activity of Theophrastus extended over the whole field of contemporary knowledge. Logical, physical, biological, psychological, ethical, political, rhetorical, and metaphysical treatises are mentioned, most of which probably differed little from the Aristotelian treatment of the same themes, though supplementary in details. On the whole, Theophrastus seems to have developed by preference the observational and scientific side of his master, and of this character are the books and fragments that have come down to us. The most important of these are two large botanical treatises, *On the History of Plants* (περὶ φυτῶν ἱστορίας), in nine books (originally ten), and *On the Causes of Plants* (περὶ φυτῶν αἰτιῶν), in six books (originally eight). These constitute the most important contributions to botanical science till we come to modern times, and furnish proof of the author's extensive and careful observation combined with a considerable critical sagacity. We also possess fragments of a *History of Physics*, a fragmentary treatise *On Stones*, a work *On Sensation* (περὶ αἰσθήσεως) in the same condition, certain metaphysical ἀπορίαι which probably once formed part of a systematic treatise, and the well-known *Ethical Characters* (ἠθικοὶ χαρακτῆρες), containing a delineation of moral types, probably an extract or compilation by a later hand from a larger ethical work of Theophrastus. Various smaller scientific fragments have been collected in the editions of J. G. Schneider (1818-21) and F. Wimmer (1886) and in Usener's *Analecta Theophrastea*.

THEOPHYLACT, a well-known Biblical commentator, was born most probably at Euripus, in Eubœa, about the middle of the 11th century. He became a deacon at Constantinople and attained a high reputation as a scholar, as is shown by the fact that he became the tutor of Constantine Porphyrogenitus, son of Michael VII., for whom he wrote his Παιδεία βασιλική. About 1078 he went into Bulgaria as archbishop of Achris. In his letter he complains much of the rude manners of the Bulgarians, and he sought to be relieved of his office, but apparently without success. His death took place after 1107.

His commentaries on the Gospels, Acts, the Pauline epistles, and the Minor Prophets are founded on those of Chrysostom, but deserve the considerable place they hold in exegetical literature for their appositeness, sobriety, accuracy, and judiciousness. His other extant works include seventy-five letters and various homilies and orations and other minor pieces. A splendid edition of the whole in Greek and Latin, with a preliminary dissertation, was published in 1754–63 by J. F. B. M. de Rossi (4 vols. fol., Venice.)

THEOPHYLACT of Simocatta. See vol. iv. p. 544.

THEOPOMPUS of Chios, a celebrated historian and rhetorician, was born about 378 B.C. In early youth he seems to have spent some time at Athens, along with his father, who had been exiled on account of his Laconian sympathies. Here he became a pupil of Isocrates, and rapidly made great progress in rhetoric: we are told that Isocrates used to say that Ephorus required the spur but Theopompus the bit (Cic., *Brutus*, § 204). At first he appears to have composed epideictic speeches, in which he attained to such proficiency that in 352–351 he gained the prize of oratory given by Artemisia in honor of her husband, although Isocrates was himself among the competitors. It is said to have been the advice of his teacher that finally determined his career as an historian,—a career for which his abundant patrimony and wide knowledge of men and places (Fr. 26) had singularly fitted him. Through the influence of Alexander, he was restored to Chios about 333, and figured for some time as one of the boldest and most uncompromising leaders of the aristocratical party in his native town. After Alexander's death he was again expelled, and took refuge with Ptolemy in Egypt, where he appears to have met with a somewhat cold reception. The date of his death is unknown.

The works of Theopompus were chiefly historical, and later writers frequently cite them as authorities. They include an *Epitome of Herodotus's History*, the *Hellenics* (Ἑλληνικά, Ἑλληνικαὶ ἱστορίαι), the *History of Philip* (Φιλιππικά), and several panegyrics and hortatory addresses, the chief of which was the *Letter to Alexander*. The genuineness of the epitome of Herodotus has been called in question; we possess only five quotations from it, preserved by grammarians or lexicographers, and consisting only of single words. The *Hellenics* was a somewhat ambitious work in 12 books, extending from 411 (where Thucydides breaks off) to 394—the date of the battle of Cnidus. A few insignificant fragments remain, but do not suffice to give us any idea of the general character of the work. By far the most ambitious history written by Theopompus was the Φιλιππικά. In this he narrated the history of Philip's reign (360–336) in 58 books with frequent digressions on the names and customs of the various races and countries of which he had occasion to speak. So numerous were these digressions that Philip

III. of Macedon reduced the bulk of the history from 58 to 16 books by cutting out those parts which had no connection with the achievements of the king. It was from this history that Diodorus and Trogus Pompeius derived much of their materials. Several fragments, chiefly anecdotes and strictures of various kinds upon the character of nations and individuals, are preserved by Athenæus, Plutarch, and others. Of the *Letter to Alexander* we possess one or two fragments cited by Athenæus, animadverting severely upon the immorality and dissipations of Harpalus. The *Attack upon Plato*, and the treatise *On Piety*, which are sometimes referred to as separate works, where perhaps only two of the many digressions in the history of Philip; some writers have doubted their authenticity.

The nature of the extant fragments fully bears out the criticisms of antiquity upon Theopompus. Their style is clear and pure, full of choice and pointed expressions, but lacking in the weight and dignity which only profound thought can supply. As we might expect in a pupil of Isocrates, he is especially careful to avoid hiatus. The artistic unity of his work suffered severely from the frequent episodes with which it was interspersed; his account of Sicily, for example, extended over several books. Another fault was his excessive fondness for romantic and incredible stories (Fr. 33, 66, 76, etc.); a collection of some of these was afterwards made and published under his name, with the title of Θαυμάσια (Diog. Laert., i. 115). He was also severely blamed in antiquity for his censoriousness, and throughout his fragments no feature is more striking than this (Fr. 54, 65, etc.). On the whole, however, he appears to have been fairly impartial. Philip himself he censures severely for drunkenness and immorality (Fr. 136, 178, 262, 298), while Demosthenes receives his warm praise (Fr. 239, 263). There can be no doubt that in the *Philippica* the world has lost a great variety of pleasant tales and historians much valuable information upon many difficult points of Greek history and life.

See Müller, *Fragmenta Historicorum Græcorum*, i. 278–333, Paris, 1885.

THEORBO. See Lute, vol. xv. p. 72.

THEOSOPHY, as its derivation implies, is a term used to denote those forms of philosophic and religious thought which claim a special insight into the Divine nature and its constitutive moments or processes. Sometimes this insight is claimed as the result of the operation of some higher faculty or some supernatural revelation to the individual; in other instances the theosophical theory is not based upon any special illumination, but is simply put forward as the deepest speculative wisdom of its author. But in any case it is characteristic of theosophy that it starts with an explication of the Divine essence, and endeavors to deduce the phenomenal universe from the play of forces within the Divine nature itself. It is thus differentiated at once from all philosophic systems which attempt to rise from an analysis of phenomena to a knowledge, more or less adequate, of the existence and nature of God. In all such systems, God is the *terminus ad quem*, a direct knowledge of whom is not claimed, but who is, as it were, the hypothesis adopted, with varying degrees of certainty in different thinkers, for the explanation of the facts before them. The theosophist, on the other hand, is most at his ease when moving within the circle of the Divine essence, into which he seems to claim absolute insight. This, however, would be insufficient to distinguish theosophy from those systems of philosophy which are sometimes called "speculative" and "absolute," and which also in many cases proceed deductively from the idea of God. In a wide sense, the system of Hegel or the system of Spinoza may be cited as examples of what is meant. Both thinkers claim to exhibit the universe as the evolution of the Divine nature. They must believe, therefore, that they have grasped the inmost principles of that nature: so much is involved, indeed, in the construction of an absolute system. But it is to be noted that, though there is much talk of God in such systems, the known universe—the world that now is—is nowhere transcended; God is really no more than the principle of unity immanent in the whole. Hence, while the accusation of pantheism is frequently brought against these thinkers, the term theosophical is never used in their regard. A theosophical system may also be pantheistic, in tendency if not in intention; but the transcendent character of its Godhead definitely distinguishes it from the speculative philosophies which might otherwise seem to fall under the same definition. An historical survey shows, indeed, that theosophy generally arises in connection with religious needs, and is the expression of religious convictions or aspirations. Now the specifically religious consciousness is not pantheistic in any naturalistic sense; God is rather regarded as the transcendent source of being and purity, from which the individual in his natural state is alienated and afar off. Theosophy accepts the testimony of religion that the present world lies in wickedness and imperfection, and faces the problem of speculatively accounting for this state of things from the nature of the Godhead itself. Theosophy is thus in some sort a mystical philosophy of the existence of evil; or at least it assumes this form in some of its most typical representatives.

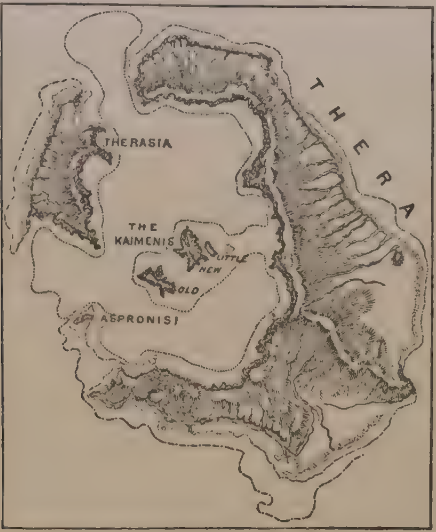
The name with which it is oftenest coupled is mysticism (see Mysticism). The latter term has properly a practical rather than a speculative reference; but it is currently applied so as to include the systems of thought on which practical mysticism was based. Thus, to take only one prominent example, the profound speculations of Meister Eckart (*q.v.*) are always treated under the head of Mysticism, but they might with equal right appear under the rubric Theosophy. In other words, while an emotional and practical mysticism may exist without attempting philosophically to explain itself, speculative mysticism is almost another name for theosophy. There is still a certain difference observable, however, in so far as the speculative mystic remains primarily concerned with the theory of the soul's relation to God, while the theosophist gives his thoughts a wider scope, and frequently devotes himself to the elaboration of a fantastic philosophy of nature.

In the above acceptation of the term, the Neoplatonic doctrine of emanations from the supra-essential One, the fanciful emanation-doctrine of some of the Gnostics (the æons of the Valentinian system might be mentioned), and the elaborate esoteric system of the Kabbalah, to which the two former in all probability largely contributed, are generally included under the head of theosophy. In the two latter instances there may be noted the allegorical interpretation of traditional doctrines and sacred writings which is a common characteristic of theosophical writers. Still more typical examples of theosophy are furnished by the mystical system of Meister Eckhart and the doctrine of Jacob Boehme (*q.v.*), who is known as "the theosophist" *par excellence*. Eckhart's doctrine asserts behind God a predicateless Godhead, which, though unknowable not only to man but also to itself, is, as it were, the essence or potentiality of all things. From it proceed, and in it, as their nature, exist, the three persons of the Trinity, conceived as stadia of an eternal self-revealing process. The eternal generation of the Son is equivalent to the eternal creation of the world. But the sensuous and phenomenal, as such, so far as they seem to imply independence of God, are mere privation and nothingness; things exist only through the presence of God in them, and the goal of creation, like its outset, is the repose of the Godhead. The soul of man, which as a microcosmos resumes the nature of things, strives by self-abnegation or self-annihilation to attain this unspeakable reunion (what Eckhardt calls being buried in God). Regarding evil simply as privation, Eckhardt does not make it the pivot of his thought, as was afterwards done by Boehme, but his notion of the Godhead as a dark and formless essence is a favorite thesis of theosophy. The followers of Eckhart are either practical mystics, or reproduce at most what may be called their master's speculative theology, till we come to Boehme.

Besides mystical theology, Boehme was indebted to the writings of Paracelsus. This circumstance is not accidental, but points to an affinity in thought. The nature-philosophers of the Renaissance, such as Nicholas of Cusa, Paracelsus, Cardan, and others, curiously blend scientific ideas with speculative notions derived from scholastic theology, from Neoplatonism, and even from the Kabbalah. Hence it is customary to speak of their theories as a mixture of theosophy and physics, or theosophy and chemistry, as the case may be. Boehme offers us a natural philosophy of the same sort. As Boehme is the typical theosophist, and as modern theosophy has nourished itself almost in every case upon the study of his works, his dominating conceptions supply us with the best illustration of the general trend of this mode of thought. His speculation turns, as has been said, upon the necessity of reconciling the existence and the might of evil with the existence of an all-embracing and all-powerful God, without falling into Manichæanism on the one hand, or, on the other, into a naturalistic pantheism that denies the reality of the distinction between good and evil. He faces the difficulty boldly, and the eternal conflict between the two may be said to furnish him with the principle of his philosophy. It is in this connection that he insists on the necessity of the Nay to the Yea, of the negative to the positive. Eckhart's Godhead appears in Boehme as the abyss, the eternal nothing, the essenceless quiet ("Ungrund" and "Stille ohne Wesen" are two of Boehme's phrases). But, if this were all, the Divine Being would remain an abyss dark even to itself. In God, however, as the condition of His manifestation, lies, according to Boehme, the "eternal nature" or the *mysterium magnum*, which is as anger to love, as darkness to light, and, in general, as the negative to the positive. This principle (which Boehme often calls the evil in God) illuminates both sides of the antithesis, and thus contains the possibility of their real existence. By the "Qual" or torture, as it were, of this diremption, the universe has qualitative existence, and is knowable. Even the three persons of the Trinity, though existing *idealiter* beforehand, attain reality only through this principle of nature in God, which is hence spoken of as their *matrix*. It forms also the matter, as it were, out of which the world is created; without the dark and fiery principle, we are told, there would be no creature. Hence God is sometimes spoken of as the father, and the eternal nature as the mother, of things. Creation (which is conceived as an eternal process) begins with the creation of the angels. The subsequent fall of Lucifer is explained as his surrender of himself to the principle of nature, instead of dwelling in the heart of God. He sought to make anger predominate over love; and he had his will, becoming prince of hell, the kingdom of God's anger, which still remains, however, an integral part of the Divine universe. It is useless to follow Boehme further, for his cosmogony is disfigured by a wild Paracelsian symbolism, and his constructive efforts in general are full of the uncouth straining of an untrained writer. In spite of these defects, his speculations have exercised a remarkable influence within the present century, notably upon the later phases of Schelling's philosophy, upon Franz von Baader, Molitor, and others.

Schelling's *Philosophical Inquiries into the Nature of Human Freedom* (1809) is almost entirely a reproduction of Boehme's ideas, and forms, along with Baader's writings, the best modern example of theosophical speculation. In his philosophy of identity SCHELLING (*q.v.*) had already defined the Absolute as pure indifference, or the identity of subject and object (of the ideal and the real), but without advancing further into theogony. He now proceeded to distinguish three moments in God, the first of which is the pure indifference which, in a sense, precedes all existence—the primal basis or abyss, as he calls it, in agreement with Boehme. But as there is nothing before or besides God, God must have the ground or cause of His existence in Himself. This is the second moment, called nature in God, distinguishable from God, but inseparable from Him. It is that in God which is not God himself; it is the yearning of the eternal One to give birth to itself. This yearning is a dumb unintelligent longing, which moves like a heaving sea in obedience to some dark and indefinite law, and is powerless to fashion anything in permanence. But in correspondence to the first stirring of the Divine existence there awakes in God Himself an inner reflexive perception, by means of which—since no object is possible for it but God—God beholds Himself in His own image. In this, God is for the first time as it were realized, although as yet only within Himself. This perception combines as understanding with the primal yearning, which becomes thereby free creative will, and works formatively in the originally lawless nature or ground. In this wise is created the world as we know it. In every natural existence there are, therefore, two principles to be distinguished—first, the dark principle, through which this is separated from God, and exists, as it were, in the mere ground; and, secondly, the Divine principle of understanding. The first is the particular will of the creature, the second is the universal will. In irrational creatures the particular will or greed of the individual is controlled by external forces, and thus used as an instrument of the universal. But in man the two principles are consciously present together, not, however, in inseparable union, as they are in God, but with the possibility of separation. This possibility of separation is the possibility of good and evil. In Boehme's spirit, Schelling defended his idea of God as the only way of vindicating for God the consciousness which naturalism denies, and which ordinary theism emptily asserts. The theosophical transformation of Schelling's doctrine was largely due to the influence of his contemporary BAADER (*q.v.*). Baader distinguishes, in a manner which may be paralleled from Boehme, between an immanent or esoteric process of self-production in God, through which He issues from His unrevealed state, and the emanent, exoteric, or real process, in which God overcomes and takes up into Himself the eternal "nature" or the principle of selfhood, and appears as a Trinity of persons. The creation of the world is still further to be distinguished from these two processes as an act of freedom or will; it cannot, therefore, be speculatively constructed, but must be historically accepted. Baader, who combined his theosophy with the doctrines of Roman Catholicism, has had many followers. Among thinkers on the same lines, but more or less independent, Molitor is perhaps the most important. SWEDENBORG (*q.v.*) is usually reckoned among the theosophists, and some parts of his theory justify this inclusion; but his system as a whole has little in common with those speculative constructions of the Divine nature which form the essence of theosophy, as strictly understood. (A. SE.)

THERA, or, as it is now called, SANTORIN, is a volcanic island in the Ægean Sea, the southernmost of the group of islands, once called Sporades, which intervene between the Cyclades and Crete. From the last-named island it is separated by a space of 60 miles of sea, but the lofty Cretan ranges of Dicte and Ida are clearly visible from it in fine weather. In shape Santorin forms a crescent, and encloses a bay on the north, east, and south, while on the western side lies the smaller island of Therasia. The encircling wall thus formed which is elliptical in shape and 18 miles round in its inner rim, is broken in two places,—towards the northwest by a strait a mile in breadth, where the water is not less than 1100 feet deep, and towards the southwest by an aperture about 3 miles wide, where the water is shallow, and an island called Aspronisi or White Island, lying in the middle, serves as a stepping-stone between the two promontories. The cliffs rise perpendicularly from the waters of the bay, in some places to the height of 1000 feet; but towards the open sea, both in Santorin and Therasia, the ground slopes gradually away, and has been converted into broad level terraces, everywhere covered with tufaceous agglomerate, which, though extraordinarily bare and ashen to the eye, is the soil which produces the famous Santorin wine. Towards the southeast rises the limestone peak of Mount Elias, the highest point of the island (1887 feet), and the only part that existed before the volcano was formed. In the middle of the basin lie three small islands, which are the centre of volcanic activity, and are called Palæa, Mikra, and Nea Kaumene, or the Old, the Little, and the New Burnt Island; the highest of these, Nea Kaumene, is 351 feet above the sea-level. Owing to the depth of the water there is no anchorage, and vessels have to be moored to the shore, except at one point in the neighborhood of the modern town, where there is a slight rim of shallow bottom. The cliffs both of Santorin and Therasia present an extraordinary appearance, being marked in horizontal bands by black lava, white porous tufa, and other volcanic strata, some parts of which are colored dark red. The modern town of Thera (or Phera, as it is more commonly pronounced) is built at the edge of these, overlooking the middle of the bay at a height of 900 feet above the water, and the houses of which it is composed are themselves peculiar, for their foundations, and in some cases their sides also, are excavated in the tufa, so that occasionally they are hardly traceable except by their chimneys; and, owing to the absence of timber,—for, with the exception of the fig, the cactus, and the palm, there are hardly any trees in the island,—they are roofed with barrel vaults of stone and cement. Both wood and water have occasionally to be imported from the neighboring islands, for there are no wells, and the rain water, which is collected in numerous cisterns, does not always suffice. The largest of the other towns or villages is that of Apanomeria, near the northern entrance, which is crowded together in a white mass, while the rocks below it are the reddest that are seen in the island.



Thera and neighboring Islands.

Santorin has from the earliest times been a centre of volcanic agency, and is closely connected with the earthquake movements to which the countries in the neighborhood of the Ægean are subject, and which have been the chief cause of the destruction of the public buildings of ancient Greece. It is hardly accurate to speak of the basin which forms the harbor as a crater, for most geologists, including Lyell, support the view that the whole of this space was once covered by a single volcanic cone, the incline of which is represented by the outward slope of Santorin and Therasia, while the position of the crater was that now occupied by the Kaumene Islands; and that, at some remote period, owing to the sinking of the strata beneath, the central portion of this, extending over an area which a French writer compares with that included within the fortifications of Paris at the time of the siege, fell in, by which convulsion the basin was formed. The principal eruptions that have taken place within historic times are that of 196 B.C., when as we learn from Strabo (i. 3, § 16, p. 57), flames rose from the water halfway between Thera and Therasia for four days, and the island of Palæa Kaumene was ejected; that of 726 A.D., during the reign of the emperor Leo the Isaurian, when an addition was made to that island, and the pumice-stone that was cast forth was carried by the waves to the shores of Asia Minor and Macedonia; that of 1573, when Mikra Kaumene appeared; that of 1650, a fearful eruption, which destroyed many lives by its noxious exhalations, and ended in the upheaval of an island in the sea to the northeast of Santorin, which afterwards subsided and became a permanent reef below the sea-level; that of 1707, when Nea Kaumene arose; and, within the recollection of the present generation, that of 1866.

Santorin and Therasia have been recently the scene of a remarkable archæological discovery. In the southern parts of both those islands prehistoric dwellings have been found at some height above the sea, and there is no reasonable cause to doubt that these date from a period antecedent to the falling in of the crater and the formation of the bay. This is proved by their position underneath the layer of tufa which covers the islands, and, moreover, by these layers of tufa being broken off precipitously, in the same way as the lava-rocks, a fact which can only be explained by the supposition that they all fell in together. The foundations of the dwellings rested, not on the tufa, but on the lava below it; and here and there between the stones branches of wild olive were found, according to a mode of building that still prevails in the island, in order to resist the shocks of earthquakes. Part of the skeleton of a man was discovered, and large vases, some containing grain, others stone instruments very carefully worked. Some of these vases were of fine yellowish earth, ornamented with brown bands; some, of smaller size, were more elaborately decorated, sometimes with lines representing foliage, and in a few instances with figures of animals; some were of red earth, without ornament; while others, of pale red earth, were of very large dimensions. No implements of metal were found. Naturally it has been the subject of much discussion what was the origin of this very primitive art. The late M. Dumont, who was the leading authority on the subject (*Les Céramiques de la Grèce Propre*, pp. 74, 75, 209), though speaking with great caution on account of the insufficiency of the evidence, inclined to the belief that it was partly derived from Phœnician influence, but at the same time that there were evident traces of native originality. Comparing it in respect of date with the other prehistoric developments of art in the neighborhood of the Ægean, he would place it later than that of Hissarlik, but earlier than those of Ialysus in Rhodes, and of Mycenæ.

In Greek legend the island of Thera was connected with the story of the Argonauts, for it was represented as sprung from a clod of earth which was presented to those heroes by Triton (Apollon., *Argonaut.*, iv. 1551 *sq.*, 1731 *sq.*). According to Herodotus (iv. 147), a Phœnician colony was established there by Cadmus—a story which proves at least the belief that there was an early settlement of that race in the island. It has even been conjectured (see vol. xviii. p. 819) that the alphabet was introduced into Greece, not, as was commonly believed, through Thebes, but by way of Thera. Subsequently, we are told, a colony from Sparta, including some of the Minyæ, was led thither by Theras, who gave the island his own name, in place of that of Calliste which it had borne before. But the one event which gave importance to Thera in ancient history was the planting of its famous colony of Cyrene on the north coast of Africa by Battus in 631 B.C., in accordance with a command of the Delphic oracle. The ancient capital, which bore the same name as the island, has been identified by an inscription as occupying a site on the eastern coast called Mesa-Vouno, between Mount Elias and the sea. The other remains of the classical period consist of walls and tombs, together with several *heroa* or small shrines, one of which, now dedicated to St. Nicholas Marmorites, who is so called in honor of his marble structure, is an almost unique specimen of a perfect Greek temple, for even the roof remains intact. After the fourth crusade, when the Byzantine empire was partitioned among the Latins, this island formed a portion of the duchy of the

Archipelago; and it was at this period that it received the name of Santorin, *i.e.*, St Irene, after the patron saint of the place, to whom Tournefort mentions that in his time nine or ten chapels were dedicated. At the present day Santorin is in a prosperous condition, for, in addition to the wine trade, which is highly remunerative, there is a large export of *pozzolana*, which has been much used for the works at Port Said in connection with the Suez Canal, since when mixed with lime, it forms a very hard cement which resists the action of the sea.

General information with regard to the Thera group will be found in Ross's *Inselreisen*, and in Lieut. Leycester's paper in vol. xx. of the *Journal of the R. Geogr. Soc.*; a very complete account of the scientific phenomena is given in Fouqué's *Santorin et ses Éruptions*. On the prehistoric antiquities, Lenormant, *Revue Archéologique*, new ser., vol. xiv., and Fouqué, *Archives des Missions*, 2d ser., vol. iv., and "Une Pompéi Antéhistorique," in the *Revue des Deux Mondes*, vol. lxxxiii., should be consulted. Of the life of the modern inhabitants a graphic account is given in Mr. Bent's *Cyclades*. (H. F. T.)

THERAMENES, an Athenian who played a prominent part in the history of Athens towards the close of the Peloponnesian War and in the revolution which followed it. He was one of the conspirators who, in 411 B.C., abolished the democracy at Athens, and substituted the oligarchy of the Four Hundred. The adhesion of the army in Samos to the democracy, however, created dissensions among the oligarchs at Athens. Theramenes supported the more moderate section, and was the chief means of destroying a fortress which the extreme section had been building at the mouth of the harbor, ostensibly as a protection against any violent movement on the part of the democrats at Samos, but really, according to Theramenes, to admit the enemy. He further accused Antiphon and Archeptolemus, members of the extreme oligarchical party, who, according to Lysias, had been his own intimate friends, and secured their capital punishment. In 410 Theramenes commanded one of the three squadrons of the Athenian fleet in the victory over the Spartans at Cyzicus. In 409 he took part in the siege of Chalcedon and the capture of Byzantium. At the battle of Arginusæ in 406 he was one of the officers deputed by the generals in command to pick up the crews of the disabled ships; but the rescue was not effected, on account, it seems, of the storm. Nevertheless, on his return to Athens, Theramenes took a leading part in accusing and procuring the condemnation to death of the generals for neglecting to rescue the men. When Athens was besieged by the Peloponnesians, Theramenes conducted the negotiations for surrendering the city, traitorously prolonging them till starvation compelled the Athenians to accept the rigorous terms imposed by Sparta. After the surrender he formed one of the notorious Thirty who, backed by a Spartan garrison, misgoverned Athens. But by opposing their excesses he incurred their suspicions, and, being denounced by Critias, the most violent of the Thirty, he was, in defiance of the forms of law, put to death (404). He submitted to his fate with a fortitude which won the admiration of his contemporaries and of posterity, and which might well have graced the close of a better life. His ability and eloquence are recognized by Thucydides, and Aristotle is said by Plutarch (*Nic.*, 2) to have reckoned him one of the three best patriots of Athens. This latter judgment is not borne out by the facts as we know them. Rather Theramenes appears as a selfish and faithless trimmer, who deserved his nickname Cothurnus (a boot which fitted either foot).

The chief authorities for his life are Thucydides, viii.; Xenophon, *Hellenica*, i., ii.; Lysias, *Contra Erat.*; Diodorus, xiii., xiv.

THERAPEUTÆ. See MONACHISM, vol. xvi. p. 725.

THERESA, ST. (1515–1582). Teresa de Cepeda, perhaps the favorite saint of modern Spain, was born at Avila, in Old Castile, on the 28th of March, 1515, —at the very time, adds her biographer, "when Luther was secreting the poison which he vomited out two year later." She was one of a large family—eight sons and three daughters. Her father was a Spanish gentleman of good family, whose time was chiefly occupied with devotional reading and works of charity. Teresa's mother, his second wife, was a beautiful woman, confined generally to a sofa by delicate health. From her her daughter appears to have inherited both delicacy of health and a remarkably susceptible imagination. She delighted in the books of knight-errantry which abounded in the library, and her children sat up at night in their nursery over the same romances. But Teresa's imagination was judiciously diverted by her father to another form of heroism. She was soon as deep in the histories of the martyrs as she had been in the tales of chivalry. She learned from these histories that martyrs passed straight to heaven without any detention in purgatory; and, being eminently practical as well as imaginative, she resolved to secure that blessing for herself. When she was seven years old, she started off with her little brother to go and seek martyrdom in the country of the Moors. They had reached the bridge on the stream which runs through the town, when an uncle met them and brought them back. Balked thus of their desire, they played at hermits, making themselves cells in the garden, and giving away their pocket money to beggars. Teresa lost her mother early, and as she grew up the vanities and flirtations of a pretty girl took the place of these pious imaginations. Her father deemed it best to send her to be educated in an Augustinian convent in the town, but without any thoughts of her adopting a religious life. She would probably have married like her sisters, had it not been for an attack of illness. She was sent away for change of air on a visit to one of her sisters, and on her way home spent some days with a saintly uncle, who was on the eve of entering a monastery, and who strongly urged her to withdraw from the world. Her father was greatly opposed to the step, but Teresa was not to be turned from what she conceived to be her duty. She was only eighteen when she left home one morning, and applied for admission at the Carmelite convent of the Incarnation. She was disappointed at first at the slackness of discipline. The sisters mixed freely in the society of Avila, receiving visits and returning them, and often absenting themselves from the cloister for months at a time. For the first three years she was constantly subject to attacks of sickness, fainting fits, and paroxysms of pain, but she prayed to St. Joseph, after which she became comparatively better, though her nervous system was completely shaken. But she appears afterwards to have accommodated herself with tolerable success to the worldliness of her environment, though not without intervals of religious misgiving. "For twenty years," she says, "I was tossed about on a stormy sea in a wretched condition, for, if I had small content in the world, in God I had no pleasure. At prayer time I watched for the clock to strike the end of the hour. To go to the oratory was a vexation to me, and prayer itself a constant effort." At one time she abandoned prayer altogether, as she found it impossible to fix her thoughts, and she abhorred the hypocrisy of mechanically repeating a form of words. It was in the year 1554 (her novitiate dated from 1534), when she was thus nearly forty, that the event known as her conversion took place, and the second part of her life began. The death of her father roused her to serious reflection, and one day, as she entered the oratory, she was struck by the image of the wounded Christ, placed there for an approaching festival. The blood was depicted as streaming over the face from the thorns and running from the side and the hands and feet. The spectacle of suffering pierced Teresa's breast; she fell in tears at the feet of the figure, and felt every worldly emotion die within her. The shock threw her into a trance, and these trances, accompanied by visions, recurred frequently in the subsequent part of her life. They have since been adduced as Divine attestations of her saintship, but the sisterhood in the convent set them down to possession by a devil; her new departure was due in their eyes to no worthier motive than the desire to be peculiar and to be reputed better than other people. Teresa herself was very humble, and thought their explanation might be true; she took her case to her confessor and to the provincial-general of the Jesuits. The latter put her under a course of discipline; she was to flog herself with a whip of nettles, to wear a haircloth plaited with broken wires that would tear the skin, and to meditate daily on the details of Christ's passion. One day, while thus occupied, her trance came upon her, and she heard a voice say, "Thou shalt have no more converse with men, but with angels." After this the trance or fit always returned when she was at prayers, and she felt that Christ was close to her. Presently she was able to see him "exactly as he was painted rising from the sepulchre." Her confessor directed her to exorcise the figure, and she obeyed with pain, but it is needless to say, in vain. The visions grew more and more vivid. The cross of her rosary was snatched from her hand one day, and when returned it was made of jewels more brilliant than diamonds, visible, however, to her alone. She had often an acute pain in her side, and fancied that an angel came to her with a lance tipped with fire, which he struck into her heart. The 27th of August is kept sacred in Spain to this mystery, which has also formed a favorite subject of Spanish painters; it forms the frontispiece of the biography which is put into the hands of Catholics. She had also visions of another description: she was shown hell with its horrors, and the devil would sit upon her breviary, belabor her with blows, and fill her cell with imps. For several years these experiences continued, and the verdict as to their source still remained far from unanimous. Meanwhile, on the broad stage of the world, the Reformation continued to spread and establish itself; and this great falling away became the subject of much searching of hearts to pious Catholics. Teresa reflected like the rest, and her experience led her to find the real cause of the catastrophe in the relaxation of discipline within the religious orders. If the ancient rules could be restored, it appeared to her that the evil might be stemmed; and she formed the project of founding a house in which all the original rules of the Carmelite order before its relaxation would be observed. She met, not unnaturally, with great opposition from the authorities of the order, and in particular from the prioress and sisters of the Incarnation, who looked upon the step as a reflection upon themselves. Nevertheless, she persevered with her scheme, being encouraged to appeal to the pope by certain priests who saw the benefit which would accrue to the church from her zeal. A private house in Avila was secretly got ready to serve as a small convent, and, when the bull arrived from Rome, Teresa went out on leave from the Incarnation and installed four poor women in the new house dedicated to her patron St. Joseph. It was on the 24th of August, 1562, that mass was said in the little chapel and the new order constituted. It was to be an order of Descalzos or Barefoots, in opposition to the relaxed parent body, the Calzados. The sisters were not to be literally shoeless, but to wear sandals of rope; they were to sleep on straw, to eat no meat, to be strictly confined to the cloister, and to live on alms without regular endowment. After lodging her four sisters, Teresa returned to the Incarnation, as in duty bound; but, when the secret was discovered, Carmelites and townspeople were alike furious. Violence, however, was prevented, and the matter was referred to the council of state at Madrid. Philip II. referred it again to the pope, and after six months a fresh bull arrived from Pius V. The provincial of her order now gave her leave to remove and take charge of her sisterhood. The number of thirteen, to which on grounds of discipline she had limited the foundation, was soon filled up, and Teresa spent here the five happiest years of her life. Her visions continued, and, by command of her ecclesiastical superiors, she wrote her autobiography containing a full account of these experiences. She herself, however, profoundly as she believed in their reality, saw the danger which attaches to such experiences, and was far from basing any claim to holiness upon them. One of her visions about this time is interesting as illustrating what is called her mysticism. She fancied that she was a mirror without frame and without dimensions, with Christ shining in the centre of it, and the mirror itself, she knew not how, was in Christ. Teresa was now encouraged to carry her work still further, for the church was girding itself to the work of the Counter-Reformation. The general of the order visited her at Avila, and gave her powers to found other houses of Descalzos, for men as well as women. The last fifteen years of her life were spent mainly in journeys with this end and in the continually growing labor of organization. She travelled in a rude cart in all weathers, and the story of her hardships and misadventures impresses us with the strength of will that animated her old and shaken frame. Convents were founded at Medina, Malaga, Valladolid, Toledo, Segovia, and Salamanca, and two at Alva under the patronage of the famous duke. Then she had three years of rest, as prioress of her old convent of the Incarnation. She next went to Seville to found a house, thus overstepping for the first time the boundaries of the Castiles, to which her authorization limited her. The latent hostility of the old order was aroused; the general ordered the immediate suppression of the house at Seville, and procured a bull from Gregory XIII. prohibiting the further extension of the reformed houses (1575). But the movement against her came from Italy, and was resented by Philip and the Spanish authorities as undue interference; and, after a fierce struggle, during which Teresa was two years under arrest at Toledo, the Carmelites were divided into two bodies in 1580, and the Descalzos obtained the right to elect their own provincial-generals (see CARMELITES). The few remaining years of Teresa's life were spent in the old way, organizing the order she had founded, and travelling about to open new convents. Sixteen convents and fourteen monasteries were founded by her efforts; she wrote a history of her foundations, which forms a supplement to her autobiography. At Burgos, during the whole of a wet autumn and winter, she endured terrible privations. Her own nuns, too, were not always as single-minded and obedient as the ideal sisterhood of her hopes had been. Those at St. Joseph in Avila mutinied for a meat diet; the prioress at Medina answered her impertinently. Her last journey of inspection was cut short at Alva, where she died on the 29th of September, 1582, and was laid in her first, but not her last, resting-place. A violet odor and a fragrant oil were said to distil from her tomb; and when it was opened nine months afterwards the flesh was found uncorrupted. A hand cut off by a fervent brother was found to work miracles, and the order became convinced that their founder had been a saint. It was resolved in 1585 to remove her remains to Avila, where she was born, the sisters at Alva being consoled by permission to retain the mutilated arm. But the family of the duke of Alva procured an order from the pope enjoining that the body should be restored to Alva, and she was accordingly laid there once more in a splendid tomb. But even then she was not allowed to rest: she was again disentombed, to be laid in a more magnificent coffin, and the greed of reverential relic-seekers made unseemly havoc of her bones.

Teresa was canonized by Gregory XV. in 1622. The honor was doubtless largely due to her asceticism and mystic visions. She called herself Teresa de Jesus, to signify the closeness of her relation to the heavenly Bridegroom, who directed all her actions. Though she deprecated excess of ascetic severity in others, she scourged herself habitually, and wore a peculiarly painful haircloth. But her life shows her to have been, besides, a woman of strong practicality and good sense, full of natural shrewdness, and with unusual powers of organization. "You deceived me in saying she was a woman," writes one of her confessors; "she is a bearded man." She was brave in the face of difficulties and dangers, pure in her motives, and her utterances, some of which have been quoted, have the true ethical ring about them. Her MSS. were collected by Philip II. and placed in a rich case in the Escorial, the key of which the king carried about with him. Besides her autobiography and the history of her foundations, her works (all written in Spanish) contain a great number of letters and various treatises of mystical religion, the chief of which are *The Way of Perfection* and *The Castle of the Soul.* Both describe the progress of the soul towards perfect union with God.

Her works, edited by two Dominicans, were first published in 1587, and have since appeared in various editions. They were soon afterwards translated into Italian, French, and Latin; an English translation of the *Life* and works (except the letters) by A. Woodhead appeared in 1669. More recently various translations of the *Life* have appeared,—by John Dalton (1851), who also translated the *Way of Perfection*, and by David Lewis (1870), followed in 1871 by the *Foundations* from the same hand. Biographies appeared soon after her death by the Jesuit Ribera, who had been her confessor (1602), and by Diego de Yepez, confessor to Philip II. (1599). Details are also given in Ribadeneyra's *Flos Sanctorum* and in Alban Butler's *Lives of the Saints.* A separate biography, with preface by Archbishop Manning, appeared in 1865, and an interesting and sympathetic account of her life is given in the *Quarterly Review* for October, 1883. THERMAL SPRINGS. See GEOLOGY, vol. x. pp. 239, 240, 241, and MINERAL WATERS.

THERMODYNAMICS. In a strict interpretation, this branch of science, sometimes called the Dynamical Theory of Heat, deals with the relations between heat and work, though it is often extended so as to include all transformations of energy. Either term is an infelicitous one, for there is no direct reference to force in the majority of questions dealt with in the subject. Even the title of Carnot's work, presently to be described, is much better chosen than is the more modern designation. On the other hand, such a German phrase as *die bewegende Kraft der Wärme* is in all respects intolerable.

It has been shown in a previous article (ENERGY) that Newton's enunciation of the conservation of energy as a general principle of nature was defective in respect of the connection between work and heat, and that, about the beginning of the present century, this *lacuna* was completely filled up by the researches of Rumford and Davy (see also HEAT). In the same article Joule's experimental demonstration of the principle, and his determination of the work-equivalent of heat by various totally independent processes, have been discussed.

But the conservation of energy, alone, gives us an altogether inadequate basis for reasoning on the work of a heat-engine. It enables us to calculate how much work is equivalent to an assigned amount of heat, and *vice versa*, provided the transformation can be effected; but it tells us nothing with respect to the percentage of either which can, under given circumstances, be converted into the other. For this purpose we require a special case of the law of transformation of energy. This was first given in Carnot's extraordinary work entitled *Reflexions sur la Puissance Motrice du Feu*, Paris, 1824.[1]

The chief novelties of Carnot's work are the introduction of the idea of a cycle of operations, and the invaluable discovery of the special property of a *reversible cycle.* It is not too much to say that, without these wonderful novelties, thermodynamics as a theoretical science could not have been developed.

Carnot's work seems to have excited no attention at the time of its publication. Ten years later (1834) Clapeyron gave some of its main features in an analytical form, and he also employed Watt's diagram for the exhibition of others. Even this, however, failed to call attention properly to the extremely novel processes of Carnot, and it was reserved for Sir W. Thomson (in 1848, and more at length in 1849) to point out to scientific men their full value. His papers on Carnot's treatise, following closely after the splendid experimental researches of Colding and Joule, secured for the dynamical theory of heat its position as a recognized branch of science. James Thomson, by Carnot's methods, predicted in 1849 the lowering of the freezing point of water by pressure, which was verified experimentally in the same year by his brother. Von Helmholtz had published, two years before, a strikingly original and comprehensive pamphlet on the conservation of energy. The start once given, Rankine, Clausius, and W. Thomson rapidly developed, though from very different standpoints, the theory of thermodynamics. The methods adopted by Thomson differed in one special characteristic from those of his concurrents,—they were based entirely on the experimental facts and on necessary principles; and, when hypothesis was absolutely required, attention was carefully directed to its nature and to the reasons which appeared to justify it.

Three specially important additions to pure science followed almost directly from Carnot's methods: (1) the *absolute* definition of temperature; (2) the thermodynamic function or entropy; (3) the dissipation of energy. The first (in 1848) and the third (in 1852) were given by W. Thomson. The second, though introduced by Rankine, was also specially treated by Clausius.

In giving a brief sketch of the science, we will not adhere strictly to any of the separate paths pursued by its founders, but will employ for each step what appears to be most easily intelligible to the general reader. And we will arrange the steps in such an order that the necessity for each may be distinctly visible before we take it.

---

[1] The author, N-L-Sadi Carnot[*] (1796–1832), was the second son of Napoleon's celebrated minister of war, himself a mathematician of real note even among the wonderful galaxy of which France could then boast. The delicate constitution of Sadi was attributed to the agitated circumstances of the time of his birth, which led to the proscription and temporary exile of his parents. He was admitted in 1812 to the École Polytechnique, where he was a fellow-student of the famous Chasles. Late in 1814 he left the school with a commission in the Engineers, and with prospects of rapid advancement in his profession. But Waterloo and the Restoration led to a second and final proscription of his father; and, though Sadi was not himself cashiered, he was purposely told off for the merest drudgeries of his service; il fut "envoyé successivement dans plusieurs places fortes pour y faire son métier d'ingénieur, compter des briques, réparer des pans de murailles, et lever des plans destinés à s'enfouir dans les cartons," as we learn from a biographical notice written by his younger brother. Disgusted with an employment which afforded him neither leisure for original work nor opportunities for acquiring scientific instruction, he presented himself in 1819 at the examination for admission to the staff-corps (état-major), and obtained a lieutenancy. He now devoted himself with astonishing ardor to mathematics, chemistry, natural history, technology, and even political economy. He was an enthusiast in music and other fine arts; and he habitually praticed as an amusement, while deeply studying in theory, all sorts of athletic sports, including swimming and fencing. He became captain in the engineers in 1827, but left the service altogether in the following year. His naturally feeble constitution, farther weakened by excessive devotion to study, broke down finally in 1832. A relapse of scarlatina led to brain fever, from which he had but partially recovered when he fell a victim to cholera. Thus died, at the early age of thirty-six, one of the most profound and original thinkers who have ever devoted themselves to science. The work named above was the only one he published. Though of itself sufficient to put him in the very foremost rank, it contains only a fragment of Sadi Carnot's discoveries. Fortunately his manuscripts have been preserved, and extracts from them have been appended by his brother to a reprint (1878) of the *Puissance Motrice.* These show that he had not only realized for himself the true nature of heat, but had noted down for trial many of the best modern methods of finding its mechanical equivalent, such as those of Joule with the perforated piston and with the internal friction of water and mercury. W. Thomson's experiment with a current of gas forced through a porous plug is also given. One sentence of extract, however, must suffice, and it is astonishing to think that it was written over sixty years ago. "On peut donc poser en thèse générale que la puissance motrice est en quantité invariable dans la nature, qu'elle n'est jamais, à proprement parler, ni produite, ni détruite. À la vérité, elle change de forme, c'est-à-dire qu'elle produit tantôt un genre de mouvement, tantôt un autre; mais elle n'est jamais anéantie."

[*] [Marie François Sadi Carnot, President of the French Republic since Dec. 2d, 1887, is a nephew of this N-L-Sadi Carnot, here biographically noticed, and a grandson of the famous war minister who was "the organizer of victory" under the French Convention, and for a short time under the empire.—AM. ED.]

1. *General Notions.*—The conversion of mechanical work into heat can always be effected completely. In fact, friction, without which even statical results would be all but unrealizable in practical life, interferes to a marked extent in almost every problem of kinetics,—and work done against friction is (as a rule) converted into heat. But the conversion of heat into work can be effected only in part, usually in very small part. Thus heat is regarded as the lower or less useful of these forms of energy, and when part of it is elevated in rank by conversion into work the remainder sinks still lower in the scale of usefulness than before.

There are but two processes known to us for the conversion of heat into work, viz., that adopted in heat-engines, where the changes of volume of the "working substance" are employed, and that of electromagnetic engines driven by thermoelectric currents (see ELECTRICITY, vol. viii. p. 90). To the latter we will not again refer. And for simplicity we will suppose the working substance to be fluid, so as to have the same pressure throughout, or, if it be solid, to be isotropic, and to be subject only to hydrostatic pressure, or to tension uniform in all directions and the same from point to point.

The state of unit mass of such a substance is known by experiment to be fully determined when its volume and pressure a e given, even if (as in the case of ice in presence of water, or of water in presence of steam) part of it is in one molecular state and part in another. But, the state being determinate, so must be the temperature, and also the amount of energy which the substance contains. This consideration is insisted on by Carnot as the foundation of his investigations. In other words, before we are entitled to reason upon the relation between the heat supplied to and the work done by the working substance, Carnot says we must bring that substance, by means of a *cycle* of operations, back to precisely its primitive state as regards volume, temperature, and molecular condition.

2. *Watt's Diagram.*—Watt's indicator-diagram (see STEAM-ENGINE) enables us to represent our operations graphically. For if OM (Fig. 1) represent the volume, at any instant, of the unit mass of working substance, MP its pressure, the point P is determinate and corresponds to a definite temperature, definite energy, etc. If the points of any curve, as PP′, in the diagram represent the successive states through which the working substance is made to pass, the work done is (*loc. cit.*) represented by the area MPP′M′. Hence, a cycle of operations, whose essential nature is to bring the working substance back to its primitive state, is necessarily represented by a *closed* boundary, such as PP′Q′Q, in the diagram. The area enclosed is the excess of the work done by the working substance over that spent on it during the cycle. [This is positive if the closed path be described clockwise, as indicated by the arrow-heads.]

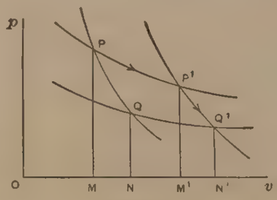

FIG. 1.

3. *Carnot's Cycle.*—For a reason which will immediately appear, Carnot limited the operations in his cycle to two kinds employed alternately during the expansion and during the compression of the working substance. The first of these involves change of volume *at constant temperature;* the second, change of volume *without direct loss or gain of heat.* [In his hypothetical engine the substance was supposed to be in contact with a body kept at constant temperature, or to be entirely surrounded by non-conducting materials.] The corresponding curves in the diagram are called *isothermals*, or lines of equal temperature, and *adiabatic* lines respectively. We may consider these as having been found, for any particular working substance, by the direct use of Watt's indicator. It is easy to see that one, and only one, of each of these kinds of lines can be found for an assigned initial state of the working substance; also that, because in expansion at constant temperature heat must be constantly supplied, the pressure will fall off less rapidly than it does in adiabatic expansion. Thus in the diagram the adiabatic lines PQ, P′Q′ cut the lines of equal temperature PP′, QQ′ downwards and to the right. Thus the boundary of the area PP′Q′Q does not cross itself. To determine the behavior of the engine we have therefore only to find how much heat is taken in along PP′ and how much is given out in Q′Q. Their difference is *equivalent* to the work expressed by the area PP′Q′Q.

4. *Carnot's Principle of Reversibility.*—It will be observed that each operation of this cycle is strictly *reversible;* for instance, to take the working substance along the path P′P we should have to spend on it step by step as much work as it gave out in passing along PP′, and we should thus restore to the source of heat exactly the amount of heat which the working substance took from it during the expansion. In the case of the adiabatics the work spent during compression is the same as that done during the corresponding expansion, and there is no question of loss or gain of heat directly.

If, however, a transfer of heat between the working substance and its surroundings have taken place on account of a finite difference of temperature, it is clear that such an operation is not reversible. Strictly speaking, isothermal expansion or contraction is unattainable in practice, but it is (without limit) more closely approximated to as the operation is more slowly performed. The adiabatic condition, on the other hand, is more closely approximated to in practice the more swiftly the operation is performed. We have an excellent instance of this in the compression and dilatation of air caused by the propagation of a sound-wave.

And now we have Carnot's invaluable proposition, *a reversible heat-engine is a perfect engine,*—perfect, that is, in the sense that no other heat-engine can be superior to it. Before giving the proof, let us see the immense consequences of this proposition. Reversibility is the sole test of perfection; so that all heat-engines, *whatever be the working substance,* provided only they be reversible, convert into work (under given circumstances) the same fraction of the heat supplied to them. The only circumstances involved are the temperatures of the source and condenser. Thus we are furnished with a general principle on which to reason about transformation of heat, altogether independently of the properties of any particular substance.

The proof, as Carnot gave it on the hypothesis of the materiality of heat, is *ex absurdo.* It is as follows. Suppose a heat-engine A to be capable of giving more work from a given amount of heat than is a reversible engine B, the temperatures of source and condenser being the same for each. Use the two as a compound engine, A working direct and B reversed. By hypothesis B requires to be furnished with part only of the work given by A to be able to restore to the source the heat abstracted by A, and thus at every complete stroke of the compound engine the source has its heat restored to it, while a certain amount of external work has been done. This would be the PERPETUAL MOTION (*q.v.*).

5. *The Basis of the Second Law of Thermodynamics.*—Carnot's reasoning, just given, is based on the hypothesis that heat (or caloric) is indestructible, and that (under certain conditions) it does work in being let down from a higher to a lower temperature, just

as does water when falling to a lower level. It is clear from several expressions in his work that Carnot was not at all satisfied with this view, even in 1824, and we have seen that he soon afterwards reached the true theory. But it is also clear that such an assumption somewhat simplifies the reasoning, for in his hypothetical heat-engine all the heat which leaves the boiler goes to the condenser, and *vice versa* in the reversed working. The precise point of Carnot's investigation where the supposed indestructibility of heat introduces error is when, after virtually saying compress from Q′ to a state Q determined by the condition that the heat given out shall be exactly equal to that taken in during the expansion from P to P′, he assumes that, on farther compressing adiabatically to the original volume, the point P will be reached and the cycle completed. J. Thomson, in 1849, rectified this by putting it in the true form: compress from Q′ to a state Q, such that subsequent adiabatic compression will ultimately lead to the state P.

We have now to consider that, if an engine (whether simple or compound) does work at all by means of heat, *less* heat necessarily reaches the condenser than left the boiler. Hence, if there be two engines A and B as before, and the joint system be worked in such a way that B constantly restores to the source the heat taken from it by A, we can account for the excess of work done by A over that spent on B solely by supposing that *B takes more heat from the condenser than A gives to it.* Such a compound engine would transform into work heat taken solely from the condenser. And the work so obtained might be employed on B, so as to make it convey heat to the source while farther cooling the condenser.

Clausius, in 1850, sought to complete the proof by the simple statement that "this contradicts the usual behavior of heat, which always tends to pass from warmer bodies to colder." Some years later he employed the axiom, "it is impossible for a self-acting machine, unaided by any external agency, to convey heat from one body to another at a higher temperature." W. Thomson, in 1851, employed the axiom, "it is impossible, by means of inanimate material agency, to derive mechanical effect from any portion of matter by cooling it below the temperature of the coldest of the surrounding objects." But he was careful to supplement this by further statements of an extremely guarded character. And rightly so, for Clerk-Maxwell has pointed out that such axioms are, as it were, only accidentally correct, and that the true basis of the second law of thermodynamics lies in the extreme smallness and enormous number of the particles of matter, and in consequence the *steadiness* of their average behavior. Had we the means of dealing with the particles individually, we could develop on the large scale what takes place continually on a very minute scale in every mass of gas,—the occasional, but ephemeral, aggregation of warmer particles in one small region and of colder in another.

6. *The Laws of Thermodynamics.*—I. When equal quantities of mechanical effect are produced by any means whatever from purely thermal sources, or lost in purely thermal effects, equal quantities of heat are put out of existence, or are generated. [To this we may add, after Joule, that in the latitude of Manchester 772 foot-pounds of work are capable of raising the temperature of a pound of water from 50° F. to 51° F. This corresponds to 1390 foot-pounds per centigrade degree, and in metrical units to 425 kilogrammemetres per calorie (see HEAT).]

II. If an engine be such that, when it is worked backwards, the physical and mechanical agencies in every part of its motions are all reversed, it produces as much mechanical effect as can be produced by any thermodynamic engine, with the same temperatures of source and refrigerator, from a given quantity of heat.

7. *Absolute Temperature.*—We have seen that the fraction of the heat supplied to it which a reversible engine can convert into work depends *only* on the temperatures of the boiler and of the condenser. On this result of Carnot's Sir W. Thomson based his absolute definition of temperature. It is clear that a certain freedom of choice is left, and Thomson endeavored to preserve as close an agreement as possible between the new scale and that of the air thermometer. Thus the definition ultimately fixed on, after exhaustive experiments, runs: "The temperatures of two bodies are proportional to the quantities of heat respectively taken in and given out in localities at one temperature and at the other respectively, by a material system subjected to a complete cycle of perfectly reversible thermodynamic operations, and not allowed to part with or take in heat at any other temperature; or, the absolute values of two temperatures are to one another in the proportion of the heat taken in to the heat rejected in a perfect thermodynamic engine, working with a source and refrigerator at the higher and lower of the temperatures respectively."[1] If we now refer again to Fig. 1. we see that, t and t' being the absolute temperatures corresponding to PP′ and QQ′, and H, H′ the amounts of heat taken in during the operation PP′ and given out during the operation Q′Q respectively, we have

$$H/t = H'/t',$$

whatever be the values of t and t'. Also, if heat be measured in terms of work, we have

$$H - H' = \text{area } PP'Q'Q.$$

Thus with a reversible engine working between temperatures t and t' the fraction of the heat supplied which is converted into work is $(t - t')/t$.

It is now evident that we can construct Watt's diagram in such a way that the lines of equal temperature and the adiabatics may together intercept a series of equal areas. Thus let PP′ (Fig. 2) be the isothermal t, and on it so take points P′, P″, P‴, etc., that, as the working substance passes from P to P′, P′ to P″, etc., t units of heat (the unit being of any assigned value) shall in each case be taken in. Let QQ′, RR′, etc., be other isothermals, so drawn that the successive areas PQ′, QR′, etc., between any two selected adiabatics, may be equal. Then, as it is clear that all the successive areas between each one pair of isothermals are equal (each representing the area t–t'), it follows that all the quadrilateral areas in the figure are equal.

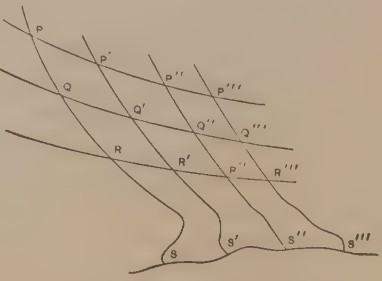

FIG. 2.

It is now clear that the area included between PP′ and the two adiabatics PQR, P′Q′R′ is essentially *finite*, being numerically equal to t. Thus the temperature for each isothermal is represented by the corresponding area. This is indicated in the cut by the introduction of an arbitrary line SS′, supposed to be the isothermal of absolute zero. The lower parts of the adiabatics also are unknown, so that we may draw them as we please, subject to the condition that the entire areas PS′, P′S″, P″S‴, etc., shall all be equal. To find, on the absolute scale, the numerical values of two definite temperatures, such as the usually employed freezing and boiling points of water, we must therefore find their *ratio* (that of the heat taken and the heat rejected by a reversible engine working between these temperatures), and *assign* the number of degrees in the interval.

---

[1] *Trans. R.S.E.*, May, 1854.

Thomson and Joule experimentally showed that this ratio is about 1.365. Hence, if we assume (as in the centigrade scale) 100 degrees as the range, the temperatures in question are 274 and 374 nearly. A full discussion of this most important matter will be found under HEAT.

8. *Entropy.*—Just as the lines PP′, QQ′, etc., are characterized by constant temperature along each, so we figure to ourselves a quantity which is characteristic of each adiabatic line,—being constant along it. The equation of last section at once points out such a quantity. If we write ϕ for its value along PQ, ϕ' for P′Q′, we may define thus

$$\phi' - \phi = \mathrm{H}/t.$$

From the statements as to the equality of the areas in Fig. 2 the reader will see at once that the area bounded by t, t', ϕ, ϕ' is $(t-t')(\phi'-\phi)$. We are concerned only with the *changes* of ϕ, not with its actual magnitude, so that any one adiabatic may be chosen as that for which $\phi = 0$.

9. *The Dissipation of Energy.*—In the before-cited article ENERGY (vol. viii. p. 187) this part of the subject has already been treated. Since that article was written Sir William Thomson has introduced the term *thermodynamic motivity* to signify "the possession the waste of which is called dissipation." We speak of a distribution of heat in a body or system of bodies as having motivity, and we may regard it from without or from within the system.

In the first case it expresses the amount of work which can be obtained by means of perfect engines employed to reduce the whole system to some definite temperature, that, say, of the surrounding medium. In the second case the system is regarded as self-contained, its hotter parts acting as sources, and its colder parts as condensers for the perfect engine.

As an instance of internal motivity we may take the case of a system consisting of two equal portions of the same substance at different temperatures, say a pound of boiling water and a pound of ice-cold water. If we neglect the (small) change of specific heat with temperature, it is found that, when the internal motivity of the system is exhausted, the temperature is about 46° C., being the centigrade temperature corresponding to the geometrical mean of the original absolute temperatures of the parts. Had the parts been simply mixed so as to dissipate the internal motivity, the resulting temperature would have been 50° C. Thus the work gained (*i.e.*, the original internal motivity) is the equivalent of the heat which would raise two pounds of water from 46° C. to 50° C. [115° F. to 122° F.].

As an instance of motivity regarded from without we may take the simple case of the working substance in § 2, on the hypothesis that there is an assigned lower temperature limit. As there is no supply of heat, it is clear that the maximum of work will be obtained by allowing the substance to expand adiabatically till its temperature sinks to the assigned limit.

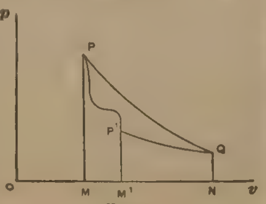

FIG. 3.

Thus if P (Fig. 3) be its given position on Watt's diagram, PQ the adiabatic through P, and P′Q the isothermal of the lower temperature limit, Q is determinate, and the motivity is the area PQNM. If, again, we wish to find the motivity when the initial and final states P and P′ are given, with the condition that the temperature is not to fall below that of the state P′, the problem is reduced to finding the course PP′ for which the area PP′M′M is greatest. As no heat is supplied, the course cannot rise above the adiabatic PQ, and by hypothesis it cannot fall below the isothermal P′Q,—hence it must be the broken line PQP′. Thus, under the circumstances stated, the motivity is represented by the area MPQP′M′. If any other lawful course, such as PP′, be taken, there is an unnecessary waste of motivity represented by the area PQP′.

10. *Elementary Thermodynamic Relations.*—From what precedes it is clear that, when the state of unit mass of the working substance is given by a point in the diagram, an isothermal and an adiabatic can be drawn through that point, and thus ϕ and t are determinate for each particular substance when p and v are given. Thus any two of the four quantities p, v, t, ϕ may be regarded as functions of the other two, chosen as independent variables. The change of energy from one state to another can, of course, be expressed as in § 9, above. Thus putting E for the energy, we have at once

$$d\mathrm{E} = t d\phi - p dv \quad . \quad . \quad . \quad . \quad . \quad (1)$$

if ϕ and v be chosen as independent variables, and if heat be measured, as above, in units of work. This equation expresses, in symbols, the two laws of thermodynamics. For it states that the gain of energy is the excess of the heat supplied over the work done, which is an expression of the first law. And it expresses the heat supplied as the product of the absolute temperature by the gain of entropy, which is a statement of the second law in terms of Thomson's mode of measuring absolute temperature.

But we now have two equations in partial differential coefficients:

$$\left(\frac{d\mathrm{E}}{d\phi}\right) = t, \qquad \left(\frac{d\mathrm{E}}{dv}\right) = -p.$$

from these we have two expressions for the value of

$$\left(\frac{d^2\mathrm{E}}{dv\,d\phi}\right).$$

Equating them, we are led to the thermodynamic relation

$$\left(\frac{dt}{dv}\right) = -\left(\frac{dp}{d\phi}\right),$$

the differential coefficients being again partial.

This expresses a property of all "working substances," defined as in § 1. To state it in words, let us multiply and divide the right hand side by t, and it then reads:

The rate at which the temperature falls off per unit increase of volume in adiabatic expansion is equal to the rate at which the pressure increases per dynamical unit of heat supplied at constant volume multiplied by the absolute temperature.

To obtain a similar result with v and t as independent variables, we have only to subtract from both sides of (1) the complete differential $d\,(t\phi)$, so that

$$d(\mathrm{E} - t\phi) = -\phi dt - p dv.$$

Proceeding exactly as before, we find

$$\left(\frac{d\phi}{dv}\right) = \left(\frac{dp}{dt}\right),$$

in words this result runs (when both sides are multiplied by t):

The rate of increase of pressure with temperature at constant volume, multiplied by the absolute temperature, is equal to the rate at which heat must be supplied per unit increase of volume to keep the temperature constant.

Very slight variations of the process just given obtain the following varieties of expression:

$$\left(\frac{dv}{d\phi}\right) = \left(\frac{dt}{dp}\right) \text{ and } \left(\frac{dv}{dt}\right) = -\left(\frac{d\phi}{dp}\right),$$

which are to be interpreted as above.

11. *Increase of Total Energy under various Conditions.*—The expression (1) of § 10 may be put in various forms, each convenient for some special purpose. We give one example, as sufficiently showing the processes employed. Thus, suppose we wish to find how the energy of the working substance varies with its volume when the temperature is kept constant, we must express $d\mathrm{E}$ in terms of dv and dt. Thus

$$d\mathrm{E} = t\left(\frac{d\phi}{dt}\right)dt + t\left(\frac{d\phi}{dv}\right)dv - p dv.$$

But we have, by § 10, under present conditions

$$\left(\frac{d\phi}{dv}\right) = \left(\frac{dp}{dt}\right).$$

Hence
$$\left(\frac{d\mathrm{E}}{dv}\right) = t\left(\frac{dp}{dt}\right) - p,$$

a result assumed in a previous article (Radiation, vol. xx. p. 221.)

If the working substance have the property (that of the so-called "ideal" perfect gas)

$$pv=\mathrm{R}t,$$

we see that, for it,

$$\left(\frac{d\mathrm{E}}{dv}\right)=0.$$

The energy of (unit mass of) such a substance thus depends upon its temperature alone.

12. *Specific Heat of a Fluid.*—Specific heat in its most general acceptation is the heat required, under some given condition, to raise the temperature of unit mass by one degree. Thus it is the heat taken in while the working substance passes, by some assigned path, from one isothermal t to another $t+1$; and this may, of course, have as many values as there are possible paths. Usually, however, but two of these paths are spoken of, and these are taken parallel respectively to the co-ordinate axes in Watt's diagram, so that we speak of the specific heat at constant volume or at constant pressure. In what follows these will be denoted by c and k respectively.

Take v and p for the independent variables, as in the diagram, and let k be the specific heat corresponding to the condition

$$f(v,p)=\text{const.}$$

Then
$$kdt=td\phi=t\left(\frac{d\phi}{dv}dv+\frac{d\phi}{dp}dp\right);$$

while
$$0=\frac{df}{dv}dv+\frac{df}{dp}dp,$$

and
$$dt=\frac{dt}{dv}dv+\frac{dt}{dp}dp.$$

Thus
$$k=t\frac{\dfrac{d\phi}{dv}\dfrac{df}{dp}-\dfrac{d\phi}{dp}\dfrac{df}{dv}}{\dfrac{dt}{dv}\dfrac{df}{dp}-\dfrac{dt}{dp}\dfrac{df}{dv}}.$$

This expression vanishes if f and ϕ vary together, *i.e.*, in adiabatic expansion, and becomes infinite if f and t vary together, *i.e.*, in isothermal expansion; as might easily have been foreseen. Otherwise it has a finite value. It is usual, however, to choose v and t as independent variables, while we deal analytically (as distinguished from diagrammatically) with the subject. From this point of view we have

$$kdt=t\left(\frac{d\phi}{dv}dv+\frac{d\phi}{dt}dt\right).$$

But the last term on the right is, by definition, cdt; so that

$$(k-c)dt=t\frac{d\phi}{dt}dv,$$

with the condition

$$\frac{df}{dt}dt+\frac{df}{dv}dv=0.$$

Thus
$$k-c=-t\frac{d\phi}{dv}\frac{df}{dt}\Big/\frac{df}{dv},$$

which is a perfectly general expression. As the most important case, let f represent the pressure, then we see, by § 10, that

$$\frac{d\phi}{dv}=\frac{dp}{dt},$$

and the formula becomes

$$k-c=-t\left(\frac{dp}{dt}\right)^2\Big/\frac{dp}{dv}.$$

13. *Properties of an Ideal Substance which follows the Laws of Boyle and Charles.*—Closely approximate ideas of the thermal behavior of a gas such as air, at ordinary temperatures and pressures, may be obtained by assuming the relation

$$pv=\mathrm{R}t,$$

which expresses the laws of Boyle and Charles. Thus, by the formula of last section, we have at once

$$k-c=t\frac{\mathrm{R}^2}{v^2}\Big/\frac{p}{v}=\mathrm{R},$$

a relation given originally by Carnot.

Hence, in such a substance,

$$d\phi=c\frac{dt}{t}+(k-c)\frac{dv}{v},$$

or
$$\phi-\phi_0=c\log t+(k-c)\log v.$$

In terms of volume and pressure, this is

$$\phi-\phi_0=c\log p/\mathrm{R}+k\log v,$$

or
$$pv^{k/c}=\mathrm{R}e^{(\phi-\phi_0)/c},$$

the equation of the adiabatics on Watt's diagram.

This is (for ϕ constant) the relation between p and v in the propagation of sound. It follows from the theory of wave-motion (Hydromechanics) that the speed of sound is

$$\sqrt{\frac{k}{c}\mathrm{R}t},$$

where t is the temperature of the undisturbed air. This expression gives, by comparison with the observed speed of sound, a very accurate determination of the ratio k/c in terms of R. The value of R is easily obtained by experiment, and we have just seen that it is equal to $k-c$; so that k and c can be found for air with great accuracy by this process,—a most remarkable instance of the indirect measurement of a quantity (c) whose direct determination presents very formidable difficulties.

14. *Effect of Pressure on the Melting or Boiling Point of a Substance.*—By the second of the thermodynamic relations in § 10, above, we have

$$\left(\frac{dp}{dt}\right)=\left(\frac{d\phi}{dv}\right),$$

so that

$$\delta p=\left(\frac{dp}{dt}\right)\delta t+\left(\frac{dp}{dv}\right)\delta v=\left(\frac{d\phi}{dv}\right)\delta t+\left(\frac{dp}{dv}\right)\delta v.$$

But, if the fraction e of the working substance be in one molecular state (say liquid) in which V_0 is the volume of unit mass, while the remainder $1-e$ is in a state (solid) where V_1 is the volume of unit mass, we have obviously

$$v=e\mathrm{V}_0+(1-e)\mathrm{V}_1.$$

Let L be the latent heat of the liquid, then

$$\left(\frac{d\phi}{dv}\right)=\frac{td\phi}{t(\mathrm{V}_0-\mathrm{V}_1)de}=\frac{\mathrm{L}}{t(\mathrm{V}_0-\mathrm{V}_1)}.$$

Also, as in a mixture of the same substance in two different states, the pressure remains the same while the volume changes at constant temperature, we have $dp/dv=0$, so that finally

$$\delta t=\frac{t(\mathrm{V}_0-\mathrm{V}_1)}{\mathrm{L}}\delta p,$$

which shows how the temperature is altered by a small change of pressure.

In the case of ice and water, V_1 is greater than V_0, so the temperature of the freezing-point is lowered by increase of pressure. When the proper numerical values of V_0, V_1, and L are introduced, it is found that the freezing-point is lowered by about 0.0074° C. for each additional atmosphere.

When water and steam are in equilibrium, we have V_0 much greater than V_1, so that the boiling-point (as is well known) is raised by pressure. The same happens, and for the same reason, with the melting-point, in the case of bodies which *expand* in the act of melting, such as beeswax, paraffin, cast-iron, and lava. Such bodies may therefore be kept solid by sufficient pressure, even at temperatures far above their ordinary melting points.

This is, in a slightly altered form, the reasoning of James Thomson, alluded to above as one of the first striking applications of Carnot's methods made after his work was recalled to notice.

15. *Effect of Pressure on Maximum Density Point of Water.*—One of the most singular properties of water at atmospheric pressure is that it has its maximum density at 4° C. [39° F.]. Another, first pointed out by Canton in 1764, is that its compressibility (per atmosphere) is greater at low than at ordinary temperatures,—being, according to his measurements, 0.000,049 at 34° F., and only 0.000,044 at 64° F. It is easy to see (though it appears to have been first pointed out by Puschl in 1875) that the second of these properties involves the *lowering* of the maximum density point by increase of pressure. To calculate the numerical amount of this effect, note that the expansibility, like all other thermal properties, may be expressed as a function of any two of the quantities p, v, t, ϕ; say in the present case p and t. Then we have for the expansibility

$$e=\frac{1}{v}\left(\frac{dv}{dt}\right)=\left(\frac{d}{dt}\right)\log v=f(p,t).$$

Also the compressibility may be expressed as

$$\mathfrak{C}=-\frac{1}{v}\left(\frac{dv}{dp}\right)=-\left(\frac{d}{dp}\right)\log v.$$

The relation between small simultaneous increments of pressure and temperature, which are such as to leave the expansibility unchanged, is thus

$$\left(\frac{de}{dt}\right)\delta t+\left(\frac{de}{dp}\right)\delta p=0.$$

Now the expansibility is zero at the maximum density point, for which therefore this equation holds. But the equations above give

$$\left(\frac{de}{dp}\right)=\left(\frac{d^2}{dp\,dt}\right)\log v=-\left(\frac{d\mathfrak{C}}{dt}\right);$$

so that

$$\left(\frac{de}{dt}\right)\delta t - \left(\frac{d\mathfrak{c}}{dt}\right)\delta p = 0.$$

The volume of water at low temperatures under atmospheric pressure varies approximately as

$$1 + \frac{(t-4)^2}{144{,}000}$$

Thus we have $\left(\frac{de}{dt}\right) = \frac{1}{72{,}000}$ nearly; and from Canton's experimental result above stated we gather that (roughly at least)

$$\left(\frac{d\mathfrak{c}}{dt}\right) = -0.000{,}005\,\frac{1.8}{30} = -0.000{,}000{,}3;$$

from which the formula gives — 0.02° C. nearly for the change of the maximum density point due to one additional atmosphere.

Recent investigations, carried out by direct as well as by indirect methods, seem to agree in showing that the true value is somewhat less than this, viz., about —0.018° C.; so that water has its maximum density at 0° C. when subjected to about 223 atmospheres. Thus, taking account of the result of § 14 above, we find that the maximum density point coincides with the freezing-point at —2.8° C. under an additional pressure of about 377 atmospheres, or (say) 2.5 tons weight per square inch.

16. *Motivity and Entropy, Dissipation of Energy.*—The motivity of the quantity H of heat, in a body at temperature *t*, is

$$H(t-t_0)/t,$$

where t_0 is the lowest available temperature.

The entropy is expressed simply as

$$H/t,$$

being independent of any limit of temperature.

If the heat pass, by conduction, to a body of temperature t' (less than t, but greater than t_0), the change of motivity (*i.e.*, the dissipation of energy) is

$$Ht_0\left(\frac{1}{t} - \frac{1}{t'}\right),$$

which is of course *loss*; while the corresponding change of entropy is the *gain*

$$H\left(\frac{1}{t'} - \frac{1}{t}\right).$$

The numerical values of these quantities differ by the factor t_0, so that, if we could have a condenser at absolute zero, there could be no dissipation of energy. But we see that Clausius's statement that the entropy of the universe tends to a maximum is practically merely another way of expressing Thomson's earlier theory of the dissipation of energy.

When heat is exchanged among a number of bodies, part of it being transformed by heat-engines into work, the work *obtainable* (*i.e.*, the motivity) is

$$\Sigma(H) - t_0\Sigma(H/t).$$

The work *obtained*, however, is simply

$$\Sigma(H).$$

Thus the waste, or amount needlessly dissipated, is

$$-t_0\Sigma(H/t).$$

This must be essentially a positive quantity, except in the case when perfect engines have been employed in *all* the operations. In that case (unless indeed the unattainable condition $t_0 = 0$ were fulfilled)

$$\Sigma(H/t) = 0,$$

which is the general expression of reversibility.

17. *Works on the Subject.*—Carnot's work has, as we have seen, been reprinted. The scattered papers of Rankine, Thomson, and Clausius have also been issued in collected forms. So have the experimental papers of Joule. The special treatises on *Thermodynamics* are very numerous; but that of Clerk-Maxwell (*Theory of Heat*), though in some respects rather formidable to a beginner, is as yet far superior to any of its rivals. (P. G. T.)

THERMOELECTRICITY. See ELECTRICITY, vol. viii. p. 88 *sq.*

THERMOMETER, an instrument for detecting and measuring differences in temperature. The name is usually restricted to instruments adapted for use at moderate temperatures; those for measuring high temperatures are termed pyrometers (see PYROMETER). Thermometry has been treated theoretically under HEAT (see vol. xi. p. 498 *sq.*). It here remains to trace the history of thermometers, and to describe the principal forms in use.

History.—The honor of inventing the thermometer has been given to several natural philosophers of the 16th century; the claims of Robert Fludd are more tangible than those of Drebbel and Santorio, but the instrument invented by Galileo before 1597 seems best entitled to be considered the precursor of accurate thermometers. All the early instruments were air thermoscopes, and, until the variations of atmospheric pressure were discovered, their use was only deceptive. Galileo's thermometer (Fig. 1) consisted of a glass bulb containing air, terminating below in a long glass tube which dipped into a vessel containing a colored fluid. The variations of volume of the enclosed air caused the fluid to fall or rise in the tube, to which an arbitrary scale was attached. The great step in advance of inventing the alcohol thermometer is also due to Galileo, but the date (probably 1611 or 1612) is not precisely known. Rinieri certainly had alcohol thermometers made before 1647, and they are referred to as familiarly known in the oldest memoirs of the Accademia del Cimento (1667). In form they resembled those now in use; they had large spherical (or, occasionally, cylindrical or helical) bulbs, and the degrees intended to represent thousandths of the volume of the reservoir were marked with beads of enamel fused on to the stem (Fig. 2). All the Florentine instruments were graduated in the same way, but the scale was arbitrary, and the recorded readings were accordingly supposed for a long time to be useless. In 1829 the fortunate discovery by Antinori of a number of those early Florentine thermometers enabled their scale to be ascertained and translated into known degrees. The temperature of melting ice was marked by them as 13.5, while 50 corresponded with 55° C. No means of comparing observations made by thermometers of different manufacture existed until certain fixed points of universal accessibility were discovered. The thermal conditions of freezing water were studied with great care, but natural congelation was generally supposed to take place at variable temperatures, until Fahrenheit proved that, however much water could be cooled down without freezing, the temperature when ice began to form was always the same. Hooke, in 1665 (*Micrographia*, p. 38), describes the manufacture and graduation of comparable spirit thermometers with the freezing point of water as the zero of their scales, and he evidently recognized it as fixed. Halley in 1693 stated that the temperature of boiling water is constant, and this was again proved by Amontons in 1702. In 1694 Renaldeni of Padua proposed to graduate thermometers by taking as standards of temperature mixtures of definite volumes of ice-cold and boiling water. This method, although theoretically admirable (see HEAT, vol. xi. p. 499), is defective in practice. Seven years later Newton proposed anonymously (*Phil. Trans.*, 1701, vol. xxii. p. 824) a thermometer scale on which the temperature of freezing water was 0°, and that of the blood of a healthy man 12°. Continuing the graduation of a linseed-oil thermometer above this point, he found that water boiled at 34°. Fahrenheit in 1714 took as fixed points the temperature of the human body and that of a mixture of ice and sal ammoniac or common salt. In 1721 he made a mercury thermometer according to Halley's suggestion of 1693, and by means of it he proved the dependence of the boiling point on pressure. It was not until after Fahren-

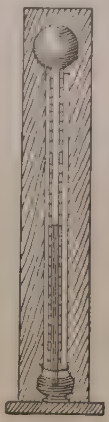

FIG. 1.

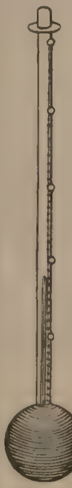

FIG. 2.

heit's death that the freezing and boiling points of water were universally accepted as fixed points on the thermometric scale. The thermometer has remained unchanged in its main features since the middle of the 18th century. Mercury has been found the most convenient fluid for ordinary use, in spite of the advantages (HEAT, vol. xi. p. 500 *sq.*) presented by lighter and more volatile liquids. Graduation of thermometers, by marking off volumes of the stem equal to a given fraction of the capacity of the bulb, although reintroduced by Réaumur in 1730, has now been entirely discontinued.

The idea of a self-registering thermometer early presented itself. Many forms were devised by natural philosophers and instrument-makers. That of Sixe, in 1782, a precursor of which, dating from the 17th century, is preserved amongst the instruments of the Florentine Academy, was the most successful.

Scales.—The absolute zero of temperature is the logical beginning of a thermometric scale, but some point easy of reference is desirable, and this is found in the temperature at which ice melts and water freezes. The second accepted fixed point is that at which distilled water boils under the pressure of 760 millimetres (29.92 in.) of mercury. For the division of the space between the two fixed points into degrees of convenient length only three of the innumerable methods proposed have survived, and one of these, the centigrade, is rapidly becoming universal. The oldest system, that of Fahrenheit, dates from 1724. It is used for meteorological purposes, and popularly, in Great Britain, the British colonies, and the United States. The freezing point is marked 32° and the boiling point of water 212°. At first Fahrenheit employed a scale of 180 degrees; the zero was placed at "temperate" (9° C.); 90° at "blood-heat," the point to which the alcohol rose when the thermometer was placed under the arm of a healthy man; and — 90° at the temperature of a mixture of ice and salt, then believed to be the greatest possible cold. In 1714 Fahrenheit changed his scale at the suggestion of the Danish astronomer Roemer, placed 0° at his "absolute zero," and divided the space between that and the warmth of the human body into 24 degrees. The freezing point of water thus became 8°. For convenience, these long degrees were divided into quarters, which were afterwards termed degrees; thus the freezing point became 32° and blood-heat 96°. A mercury thermometer graduated in this way, with divisions of equal length continued above blood-heat, registered 212° in boiling water. Thus the Fahrenheit scale came from a duodecimal reckoning.

De Lisle, in 1724, introduced a scale in which the boiling point of water was marked 0° and the temperature of the cellars of the Paris Observatory 100°. He afterwards adopted the freezing point of water as his upper fixed point, and called it 150°. This scale was used for many years in Russia, but is now obsolete.

In 1730 Réaumur made alcohol thermometers with their zero at the freezing point of water, and degrees of one-thousandth of the volume of the bulb. On some of these the boiling point of water was 80°; but the instruments were defective in principle and very unequal in their indications. Deluc introduced mercury thermometers graduated from 0° in melting ice to 80° in boiling water, and these, with Réaumur's name attached, are in use for popular purposes in Germany, Holland, and other parts of the Continent.

Celsius adopted a centesimal scale in 1742. The boiling point was marked 0° and the freezing point of water 100°. Linnæus introduced the mode of reckoning from 0° in melting ice to 100° in boiling water, which is now known as the centigrade, and is used universally in laboratories, and in all except English-speaking countries for every scientific purpose.

Fahrenheit's scale is convenient for meteorological work on account of its short degrees, admitting of great accuracy in reading and compactness in recording, and on account of its low zero, which makes it possible in temperate climates to dispense with negative quantities. On the other hand, the centigrade scale is on the whole so convenient, its use is so nearly universal, and the advantage of a uniform system is so great that it must ultimately be adopted for all purposes.[1]

AIR THERMOMETER.—Under constant pressure gases expand equally for equal increments of heat. Hence, when an air thermometer is graduated between two fixed points, the graduation may be continued above and below these points in degrees of the same length; and any number of air thermometers so made will agree amongst themselves at every temperature. The principle of air thermometers is treated of in HEAT (*ut sup.*), and examples of special forms are described in that article and in PYROMETER. The air thermometer is the ultimate standard of reference to which all other thermometers are referred.

ALCOHOL THERMOMETER.—Alcohol, the first liquid used for thermometric purposes, possesses numerous advantages, and on account of its low freezing point it is always used for observations in polar regions. Alcohol thermometers are graduated by fixing the freezing point in melting ice and by comparison with a mercury or air thermometer at several higher and lower temperatures. Recently low-temperature thermometers have been verified at Kew in melting mercury at the temperature of — 40. The law of expansion of alcohol in glass at low temperatures is not known with such precision as to make the minimum indications of Arctic expeditions entirely trustworthy. The graduation of ordinary minimum alcohol thermometers used for meteorological purposes is effected by comparison with mercury standards, and their indications, so far as this source of uncertainty is concerned, may consequently be relied on.

MERCURY IN GLASS THERMOMETER. — The simplest form is the *Weight Thermometer*, a large glass bulb terminating in a capillary tube, and filled with a known weight of mercury at 0° C. The weight of mercury that escapes when the apparatus is heated to 100° is determined, and the temperature of any enclosure is then ascertained by placing in it the thermometer filled at zero, and weighing the liquid that runs out. Thermometers on this principle were used by Regnault in his celebrated researches on steam.

Standard Thermometers.—The tube is sometimes made with elliptical bore to ensure visibility of the mercury column, but it is usually circular in section. The internal diameter must be as nearly as possible uniform. This is tested by a preliminary calibration in which a short thread of mercury is measured in different parts of the tube. The length of stem and the range of the thermometer having been decided upon, the size of the bulb is calculated from the known expansibility of mercury and the section of the bore. The bulb is made as nearly as possible the required size, either by blowing it from a tube or preferably by forming it of a glass cylinder, and attached to the stem. The bulb is usually cylindrical in form and it must be uniform in thickness. The utmost care requires to be exercised to keep the bulb and stem dry and clean and to fill them with pure mercury recently distilled. The mercury is boiled in the thermometer for some time to drive out all traces of air and moisture, and the point of the stem is sealed off. If the thermometer is not intended to measure temperatures up to the boiling point of mercury, an expansion should be made at the top of the tube to prevent bursting from accidental overheating. Under HEAT (vol. xi. pp. 500 and 501) the changes of volume which thermometer bulbs undergo in cooling and for a long time afterwards are discussed. The process of annealing by heating to a temperature exceeding 400° C. [or 752° F.] for some hours as originally proposed by Person,[2] or in vapor of mercury for several days as recently practiced at Kew, renders the thermometer much less liable to suffer change of zero by the lapse of time or by heating to any lower temperature. All instruments of precision should be treated in this way, or kept for several years after they have been filled and sealed before they are graduated.

---

[1] The process of converting readings of any one of the three existing scales into those of any other is a simple matter of proportion. They stand in the ratio of 80 : 100 : 180 (32 being subtracted from Fahrenheit temperatures before the calculation is made, and added to the result when converting from Réaumur or centigrade into Fahrenheit). An easy rule for changing centigrade readings into Fahrenheit mentally is—multiply the centigrade temperature by 2, subtract one-tenth of the product, and add 32: *e.g.*, 10° C. = 20 — 2 + 32 = 50° F. These rules are only to be applied to thermometers made with all modern precautions. When the boiling point was determined by immersing the bulb of the thermometer in boiling water or in steam at any pressure other than 760 mm. appropriate corrections have to be applied. For a detailed historical account, see Renou, "Histoire du Thermomètre," *Annuaire Soc. Mét. de France*, 1876.

[2] *Comptes Rendus*, xix., 1844, p. 1314.

The first fixed point on the scale is marked at the place where the mercury stands when the thermometer is buried in melting ice from which the water is allowed to drain away, the second at the place where the mercury stands when the thermometer is immersed in steam of water boiling freely under the pressure of 760 mm. (29.92 inches) of mercury corrected to 0° C. The space between these may be graduated either in arbitrary equidistant divisions, as it is best to do in delicate instruments, or in degrees of any scale. Each degree centigrade is $\frac{1}{100}$ of the volume of the tube between the freezing and boiling points; if the tube is quite uniform in bore the degrees will be of equal length and may be marked off correctly by a dividing engine. If the preliminary calibration showed the tube to vary in diameter, the degree marks are often adjusted to correspond to intervals of equal volume. It is better in all cases, whether degrees or arbitrary divisions are adopted, to have them of equal length and correct the readings by the calibration curve. The scale may be continued above and beneath the fixed points in degrees or divisions of the same length.

Calibration consists in measuring the internal volume of the thermometer tube by means of a thread of mercury detached from the main column. There are several ways of doing this, for particulars of which reference may be made to the British Association *Report* on the subject (1882, pp. 145–204), where references to original memoirs are given. The best and simplest is Gay Lussac's "step by step" method.

The most recent and approved processes of manufacturing, testing, and using standard thermometers of great delicacy and high precision are described by Guillaume in his "Études Thermométriques" (*Travaux et Mémoires du Bureau International des Poids et Mesures*, v., 1886);[1] for additional information the work of Pickering cited below may also be consulted.

Comparison of Thermometers.—As the apparent expansion of mercury in glass from —39° to 100° C.[2] is very nearly proportional to the amount of heat imparted to it, a thermometer made and divided as indicated above is a natural standard. But the apparent expansion with different kinds of glass differs (see HEAT, vol. xi. pp. 503–4),[3] and, except at the fixed points or near them, mercury thermometers of different construction will only fortuitously agree absolutely among themselves or with the air thermometer. Bosscha[4] states that at 50° C. the mercury thermometer shows an error of 0.5°, other experimenters place it as high as 1°, but Mascart found it to amount only to 0.06°.[5] For purposes of ordinary experiment thermometers are compared at several temperatures with some standard instrument of known value—that of the Kew observatory for Great Britain,—and all results are stated in terms of the standard. The methods of comparison at Kew are described by Welsh (*Proc. R. S.*, vi. 181) and Whipple (*Phil. Mag.* [5], xxi., 1886, p. 27).

The reading of thermometers is greatly facilitated by the process of enamelling the back, and still more by that of entirely surrounding the instrument with enamel except over a narrow strip through which the mercury is seen.[6] The enamel must not be allowed to encroach on the bulb, for that would endanger the homogeneity and strength of the glass.

THERMOMETERS EMPLOYED FOR SPECIAL PURPOSES.—*Physical and Chemical Work.*—For all purposes of minute accuracy where thermometers are applicable standard instruments must be employed. They must be used in one position only. The stem is usually engraved with an arbitrary scale of equal divisions, the total range not exceeding 15° C., and readings are made by a cathetometer at some distance. The use of an intermediate bulb, first recommended by Person, enables the fixed points to be observed on instruments of very short range. Results of great accuracy, certainly to 0.005° C., may be obtained in this way for comparative purposes if sufficient care be taken; but the greater the sensitiveness of a thermometer the more difficult is it to obtain a series of concordant readings (HEAT, vol. xi. p. 501). Pickering[7] uses thermometers of extreme sensitiveness, in which, by conveying the excess of mercury into an expansion at the top of the stem, he secures that the same part of the short arbitrary scale is used for every temperature that has to be measured. In physical researches thermoelectric junctions are more often used than thermometers for measuring very small differences of temperature.

For ordinary work in a chemical or physical laboratory thermometers are used which can be read easily to one-tenth of a degree centigrade, and have a range from 0° to 100°, or in some cases to 350° C. They are always either engraved on the stem or graduated on an included scale (see HEAT [vol. xi. pp. 503–4], Figs. 4, 5), and are not mounted on frames of any kind. It is not necessary to calibrate such thermometers; but they should be compared with a standard at several temperatures and frequently verified in melting ice and steam of boiling water.

Zincke's chemical thermometer for high temperature has a scale commencing at 100° C. In Geissler's nitrogen thermometer the range is extended by raising the boiling point of the included mercury, the upper part of the tube being filled with rarefied nitrogen.

Meteorological.—The thermometer was early applied to the study of differences of climate, and this is still one of its most important uses. The wet and dry bulb thermometers placed in the shade give the temperature and humidity (see HYGROMETRY) of the surrounding air, but "shade" and "surrounding air" require to be defined. Shade is intended to exclude rain and prevent all radiation; and the surrounding air is that of the atmosphere in the neighborhood of the thermometer outside any shelter that may be used. The simplest way of observing is to hang up a thermometer in the shadow of some rather distant object and leave it until it acquires a steady temperature; but this method has been found impracticable and does not give very exact results.

In different countries different patterns of thermometer shelter are employed and exposure takes place at a different height above the ground. Results so obtained cannot be critically compared, and the relative mean-temperatures of the atmosphere in different countries are only known to within one or two degrees. The Stevenson double-louvred screen (see vol. xvi. p. 120), a box open below, provided with a solid roof, is used at all meteorological stations in Great Britain. It is placed four feet from the ground, and painted white outside and inside. The results derived from its use are comparable, because the conditions in which it is employed are the same, but the general introduction of a double roof would greatly add to its efficiency. Exposure outside windows or in wall boxes is the rule in Austria. In France the Renou screen is largely used; it is a flat roof one square metre in extent, and double; the thermometers are hung under it two metres from the ground. A similar roof, but of much larger size, is employed in Australia, in combination with a metal thermometer-box. A metallic box, constructed of double louvres with an air-space between, finds favor in Spain. In Russia and Switzerland Wild's shelter is extensively employed. The thermometers are enclosed in a case composed of two or three concentric zinc cylinders perforated to admit air, and placed 11 feet above the ground. They are protected by a large shelter of wood, the south wall and roof of which are double and made of solid boards, between which air circulates; the east and west sides are louvred, and the north side entirely open. A similar shelter is used in Canada, to cover a box of single sheet-iron louvres in which the thermometers are placed 4½ feet from the ground. Various systems of exposure were authorized in the United States until 1885. It was then decided, as the result of experiments[8] carried on for nearly two years, that a uniform pattern of shelter be adopted by the Signal Service. It is a single-louvred wooden box, 3 feet 6 inches long, 3 feet wide and high, with a movable bottom and a double roof. The louvres are provided with an upright flange on their inner side, designed to keep rain from the thermometers. The bottom of the shelter is to be fixed either 9 feet above a roof or 16 feet above grass.

All these screens are confessedly imperfect, although most of them are well adapted for the climates in which they are used. Numerous comparisons of different screens with each other have been made,[9] but in some cases sufficient precautions in the way of using instruments precisely similar and only dissimilarly situated have not been observed, and the results are uncertain. A critical comparison of the leading forms of thermometer shelter in use is still a desideratum.

The sling thermometer[10] (*thermomètre fronde*), a small thermometer whirled in the air at the end of a string, is often used as a standard, and gives more correct readings than most closed screens. All open screens are untrustworthy. Aitken[1] has devised a series of thermometer boxes on a new principle, radiation being taken advantage of to produce a constant draught over the thermometer bulbs by the use of a long blackened chimney. These give admirable results. Very small and bright objects are little affected by radiation: hence thermometers with bulbs of small diameter and coated with a bright deposit of gold or silver have been used without screens. The air temperature has also been calculated by means of a formula from the readings of two similar thermometers, the bulbs of which are unequally affected by radiation. Some form of sling thermometer should always be used for observations at sea; the Board of Trade screen generally employed is thoroughly objectionable, and can only give moderately good results by the exercise of great precautions on the part of the observer.[2]

[10] The first use of this instrument is usually stated to have been by Arago (*Œuvres*, 1858, viii. p. 500), but Saussure employed it for

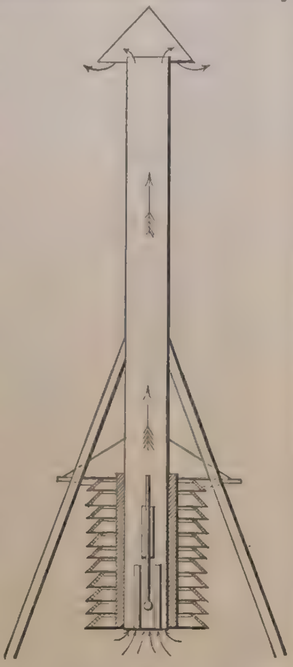

FIG. 3.—Aitken's Thermometer Screen for Maximum Thermometer.

As a rule, thermometers for meteorological purposes are made with spherical bulbs, although cylindrical reservoirs present certain advantages. To ensure perfect uniformity in registration, the bulbs should all be as nearly as possible of one size, constructed of one kind of glass, and the mounting perfectly uniform. Better-class instruments have the bulb clear of the frame, and the stem attached to a slab of metal, of porcelain, or of glass backed by wood; but sometimes they are simply fixed to a boxwood scale. In all cases they should be graduated on the stem, and compared with a standard, but in view of the uncertainty of the methods of thermometer exposure great delicacy is undesirable.

The influence of height on thermometers for ascertaining the temperature of the air has been investigated with somewhat conflicting results;[3] the disparity is at least partly due to the use of dissimilar instruments.

Registering Thermometers.—Rutherford's maximum, invented before 1790,[4] was an ordinary mercury thermometer placed horizontally; the column pushed before it a small steel index, which was left at the highest point reached. It is little used now. The maximum thermometers in common use for meteorological purposes are Negretti & Zambra's and Phillips's. The former is a modified outflow thermometer. It is made with a constriction in the tube near the bulb, past which the mercury easily expands, but cannot return when the temperature falls, as the column breaks at the narrowed point when the fluid in the bulb begins to contract. The thermometer acts horizontally, but Everett devised a modification which is hung bulb uppermost, and the mercury, as it passes the constriction, falls down and stands as a column in the inverted tube. The thermometer is set by swinging it. Phillips's maximum, claimed also by Walferdin, has a portion of the mercury thread separated from the rest by a minute bubble of air. It is placed horizontally, and, as temperature increases, the detached portion of mercury is pushed forward and is not withdrawn when the main column retreats toward the bulb on cooling. It is set for a new observation by bringing it into a vertical position and tapping it slightly. By reducing the length of the index and the bore of the stem this thermometer may be made suitable for use in any position without altering its register. Walferdin's outflow maximum thermometer is a modification of that of Lord Charles Cavendish[5] and the type of a number of similar instruments. It is set by filling the stem entirely with mercury from a lateral chamber at the top (Fig. 4). The instrument is placed vertically, and as temperature rises mercury overflows into the reservoir. To be read, the thermometer is brought back to its original temperature, then the number of degree spaces left vacant at the top of the tube shows the excess of maximum temperature above that at the time of setting.

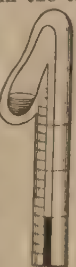

FIG. 4.

The minimum thermometer in most frequent use is that of John Rutherford, invented in 1790. It is a spirit thermometer, preferably filled with amyl alcohol to reduce risk of distillation, in the column of which a small porcelain index is included. The instrument is hung horizontally, and, as temperature falls, the index is drawn back by the surface tension of the fluid. When temperature rises, the liquid flows past the index easily, leaving it at the lowest point attained. Baudin invented a modification called the *thermomètre à marteau* in 1862; it acts vertically, the index being fixed by a spring, as in Sixe's thermometer, and set by a long glass needle included in the stem, which, when the instrument is inverted, falls on the index and drives it to the surface of the alcohol. The mercurial minimum of Casella is an instrument of great delicacy and beauty, extremely difficult to make, and requiring careful handling in its use. A side tube of wide bore *ac* (Fig. 5) is joined to the stem of an ordinary mercurial thermometer near the bulb. This tube terminates in a small chamber *ab*, cut off by a perpendicular glass diaphragm which is perforated by a hole of greater diameter than the thermometer stem. When set, the mercury in the stem indicates the actual temperature, and the chamber is empty. On the principle of Balfour Stewart's fluctuation thermometer,[6] when the instrument is heated the mercury remains stationary in the stem but expands into the chamber *ab*. When cooled, the mercury passes out of the chamber; when this is empty, the temperature has returned to that at which the instrument was set, the surface attraction of glass and mercury prevents the fluid leaving the diaphragm *b*, and all subsequent contraction takes place from the stem. The position of the mercury column in the stem marks the minimum temperature since last setting. The instrument is set by raising the bulb end and allowing all the mercury to flow from the chamber.

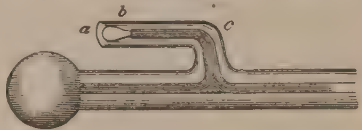

FIG. 5.

Thermometers which record the actual temperature at any required time, by a change of position produced by a clock were employed by Blackadder[7] in 1826. His process was complicated and uncertain. Negretti & Zambra have a simpler arrangement that works well. Several of their reversing thermometers (see under *Deep-Sea Thermometers*) are pivoted on a frame, and held upright by catches which are withdrawn in turn at definite intervals by an electrical arrangement regulated by a clock. Each instrument, when it reverses, preserves the record of temperature at that moment until it is set again.

No thoroughly satisfactory self-registering maximum or minimum thermometer has yet been produced. In all existing forms the indications are liable to be disturbed by shaking. Where alcohol is the fluid used, it is apt to volatilize and accumulate at the top of the tube, so registering a much lower temperature than actually occurs. It is extremely difficult also to free alcohol thermometers from air, which gradually escapes from solution in the fluid and renders the instrument untrustworthy or even useless.

Radiation Thermometers.—The intensity of solar radiation is measured by the pyrheliometer, which usually consists of a body heated by the sun's rays and a thermometer to measure the rise of temperature. In meteorology radiation is measured by thermometers simply exposed with blackened bulbs. Results of the utmost diversity are

---

wet-bulb observations, and doubtless invented it (see *Voyages dans les Alpes*, 1796, iv. p. 267).

given by different methods. As there is no means of determining the true measure of radiation, all that can be done is to have the instruments whose indications are to be compared constructed and exposed in the same way. The usual form, as suggested by Herschel, is a maximum thermometer with a spherical bulb half an inch in diameter coated with lamp-black and placed in the centre of a spherical vessel of clear glass, 2½ inches in diameter, and exhausted of air. The state of the vacuum may be shown by including a small mercurial manometer, or a radiometer, or by soldering in platinum electrodes through which a discharge can be made in the interior. It is not essential that the vacuum be very perfect; some observers prefer to employ a globe filled with dry air. For separate instruments to be comparable, Whipple[1] and Ferrel[2] have shown that the bulbs must be truly spherical, of equal thickness and size (a difference of 8 per cent. in diameter produces variations of several degrees), blackened sufficiently to absorb all radiation falling on them, and placed accurately in the centre of perfectly spherical enclosures, which must also be of equal diameter. The stem should be as small as possible in proportion to the bulb; and before being used for comparative purposes all radiation thermometers should be compared with an arbitrary standard by daily exposure for several weeks to sunshine.

Minimum radiation thermometers, intended to measure radiation from the earth at night, are usually filled with alcohol, and much ingenuity has been expended on increasing their delicacy. The bulbs are made very large relatively to the bore, and constructed so as to expose a great surface, the reservoir being often helical, lenticular, annular, spoon-shaped, forked, or even like a gridiron.

Earth Thermometers.—Saussure introduced the use of sluggish thermometers packed in non-conducting material for taking the temperature of the soil at different depths. Symon's earth thermometer on this principle is a slow-action instrument cased in felt, and is lowered by a chain into an iron tube which has previously been sunk to the required depth. It may be withdrawn and read without changing its record. The underground temperature committee of the British Association have used both slow action and self-registering thermometers for their observations in mines and shafts.[3]

Thermometers with very long stems, which can be read above ground, fitted in deep borings in the rock, are used at the observatories of Greenwich and Edinburgh for investigating earth temperature. Those at present established at the Royal Observatory, Edinburgh,[4] are the successors of a set fixed in the rock in 1837, and broken accidentally in 1876. They are placed with their bulbs at depths of 25, 12, 6, 3 feet beneath the surface respectively, and one has its bulb just covered. The readings of the intermediate thermometers supply data for correcting the long columns of alcohol in the deeper ones for the different temperatures of their different parts. Allowance may be made for this effect without calculation by utilizing the principle applied by Sainte-Claire Deville to pyrometers. A second stem, similar in every way to that of the thermometer, nearly filled with the same fluid, but hermetically sealed at the lower end, is fixed beside the thermometer stem. The fluctuations it shows are due solely to causes affecting the stem and not the bulb of the thermometer, and they are eliminated from the readings of the latter by taking account only of the difference of level of the fluid in the two tubes.

Deep-Sea Thermometers.—The earliest observations of warmth beneath the surface were made by raising samples of water in a valved box and noting the temperature when it was brought on board. Saussure, in addition to this, used sluggish thermometers, which he left immersed for several hours before reading. His latest thermometer for sea-work was filled with alcohol, and had a bulb more than an inch in diameter, which was imbedded in a mass of wax and enclosed in a stout wooden case. It attained the temperature of its surroundings very slowly, preserved it for a long time, and gave, in his hands, thoroughly trustworthy results. On the introduction of registering thermometers these were used, but the unsuspected magnitude of the effect of pressure at great depths made the earlier records entirely misleading.

A modification of Sixe's thermometer, protected from pressure by the addition of an outer bulb partially filled with a liquid, is now usually employed on deep-sea expeditions. Those used on the "Challenger," under the name of Miller-Casella thermometers, were of the form shown in Fig. 6. The tube is U-shaped, the bend and part of each limb filled with mercury, the rest of the tube, the bulb, and part of the expansion on the other side with alcohol. A steel index, held in its place by the pressure of a hair, is immersed in the spirit in each limb above the mercury, which pushes one or other before it as the temperature is rising or falling, and leaves them at points denoting the highest and lowest temperatures passed through. The indexes are set by a magnet. The "Challenger" thermometers, which were not graduated on the stems, were secured side by side with porcelain temperature scales to vulcanite frames and placed in copper cases perforated to allow a circulation of water. Tait investigated the whole subject of pressure corrections after the return of the expedition, and found that the high result obtained by a previous experimenter was due mainly to heat developed by compression of the vulcanite, which affected the thermometer in the press, but would not do so at sea. The correction which had to be applied was rather less than ½ of a degree Fahr. per mile of depth.[5] These thermometers require to be immersed from twenty minutes to half an hour before they acquire the temperature of the water, they can only be read to quarter degrees Fahr., and they simply indicate the extreme temperatures through which they have passed. Buchanan has greatly improved the instrument by reducing the bore of the tube on the minimum side, which is that most frequently used, thus giving long degrees. An arbitrary scale is engraved on the stem.[6] His mercury piezometer is affected by temperature and by pressure, and enables the actual temperature at any known depth to be found.

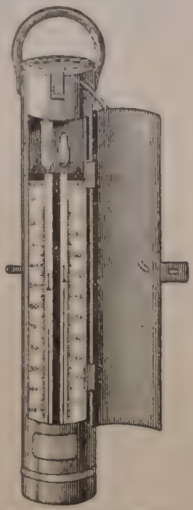

FIG. 6.—Miller-Casella Thermometer.

Aimé in 1845[7] invented a very ingenious arrangement of outflow thermometers, which were inverted by a weight slipping down the line, and registered as they were being drawn up. His instruments were accurate, but very delicate and troublesome to manage. Within the last few years Negretti and Zambra have patented several forms of modified outflow thermometers. The first instrument of the kind was complicated and unmanageable, but that now before the public is both simple and convenient. It consists of a mercury thermometer with a cylindrical bulb and a stem AC (Fig. 7) of wide bore terminating in a small pyriform aneurism. The stem is contracted and contorted just above the bulb, and when the instrument is turned upside down the mercury column breaks at this point and flows down into the tube, which is graduated in the inverted position. To protect it from pressure the thermometer is hermetically sealed in a strong glass tube, the portion of which surrounding the bulb contains a quantity of mercury secured by a ring of india-rubber cement. When the thermometer is made to turn over at any depth in water of any temperature, the record remains nearly unaltered, and, until set for a new observation, enables the actual temperature at the instant of reversal to be ascertained at any subsequent time and in any other place. The detached column standing in the tube changes its length slightly by change of temperature. A series of experiments with twelve instruments has shown that for 60° F. change of temperature there is a difference of one degree in the reading of the inverted thermometer. Hence a correction must be applied in all cases where the temperature at which the thermometer is read differs more than a few degrees from that at

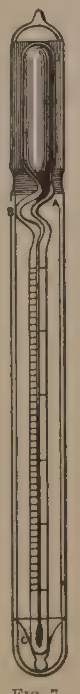

FIG. 7. Negretti and Zambra's Deep-Sea Thermometer (inverted).

[7] *Ann. Chim. Phys.* [3], 1845, xv. 1.

which it was inverted, contrary to the opinion of the German observers.[1] If a thermometer is inverted in water and read while wet, the temperature by which it should be corrected is obviously that given by the wet-bulb in air. In view of the great range of temperature experienced in deep-sea work in the tropics, the size of the little overflow cell B, which prevents mercury from the bulb from entering the tube, must be considerably increased before the thermometer can be used with safety for such purposes. The Negretti and Zambra thermometer acquires the temperature of its surroundings very rapidly (two or three minutes are usually sufficient); it can be read easily to tenths of a degree Fahr.; and, above all, it ascertains temperature at exact points of depth, and has thus revealed layers of remarkably varying temperature[2] which could not have been detected by the other instruments in use.

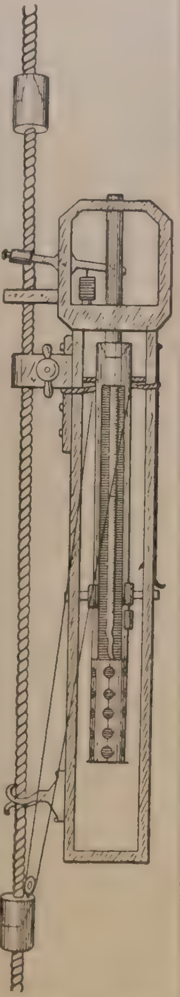

FIG. 8.—Scottish Frame for Deep-Sea Thermometer. Messenger descending to reverse the instrument.

The loaded wooden frame originally employed for reversing the thermometer is unsatisfactory, and Magnaghi's reversing gear actuated by the revolution of a small propeller set in motion by the water when the thermometer is drawn up briskly, is not to be trusted in shallow water or where there are rapid currents. When the pin is withdrawn the thermometer case turns over and is clamped by a side-spring on the frame. Rung[3] adopted a simpler and better though somewhat clumsy frame, in which the thermometer was made to turn by slipping a weight down the line. The United States Fish Commission[4] employ the thermometer in a frame adapted for use on a wire sounding line, and also actuated by a messenger, but the thermometer is not clamped on turning over. The Scottish marine station produced[5] a modification of Magnaghi's frame, the propeller being replaced by a forked lever held down by a spiral spring and raised when the thermometer is to be reversed by the impact of a Rung's messenger (Fig. 8). A messenger placed on the line below, and hung by a loop to the upper groove of the thermometer, is let go when the thermometer turns and reverses another instrument lower down. Instead of being lashed to the sounding line the frame is retained by a ram's horn spiral below and clamped by a small vice at the upper end. Buchanan has modified and simplified the frame, combining its mode of attachment to the line with the American method of reversing.

Neumayer[6] has attempted to use a photographic thermograph for deep-sea work, the light being supplied by a Geissler tube excited by a small battery. Siemens's electrical thermometer has also been experimented with,[7] but has hardly been brought to a practicable state, and the same may be said for the use of thermoelectric junctions.

Hypsometer.—The boiling-point thermometer or hypsometer may be used to obtain an independent measure of the pressure of the atmosphere, and so to determine an altitude or verify an aneroid barometer. It consists of a very delicate mercury thermometer graduated only for 20 or 25 degrees Fahr. in the neighborhood of the boiling point of water and divided on the stem into tenths. A large aneurism on the tube a little above the bulb should allow the freezing point to be verified from time to time on the portion of stem beneath it. The thermometer is hung in a cylindrical tin vessel in which water is boiled by a spirit lamp placed underneath. The bulb must be raised considerably above the level of the water, and the whole stem to the top of the mercury column immersed in the steam. After steam has been escaping freely for some time the temperature is read, and by reference to a table the barometric pressure, and consequently the altitude, is obtained.

Clinical Thermometers.—The first use to which thermometers were applied was the study of the temperature of the blood in fevers; and the constancy of the temperature of the healthy human body was for a century considered sufficient to entitle it to the position of a fixed point in graduating thermometers. The increased importance now attached to temperature in disease has led to the production of many forms of clinical thermometer. The large instruments intended to be read *in situ* are now entirely superseded by small maximum self-registering thermometers. Graduation is carried to one-fifth of a degree, and the usual range is about 25 degrees Fahr.,—from 85° or 90° to 110° or 115°. Olive-shaped bulbs have been used, but a cylindrical form is most common. There should be an arrangement like that suggested for hypsometers to enable the freezing point to be verified. Casella's thermometer on Phillips's system has a small expansion on the stem, followed by a contraction, to prevent the index following the rest of the mercury into the bulb when the instrument is not in use. The "half-minute thermometer" is quick in action; it has a bulb of very small diameter and an extremely fine bore, the mercury thread being rendered visible by Hicks's arrangement of a lens-fronted stem. Immisch's avitreous thermometer is recommended for clinical use on account of its small size, convenient shape, and non-liability to get out of order.

Thermometers for Technical Purposes.—These are made in an infinite variety of forms, adapted to the various processes of manufacture and industry. The scale is often dispensed with in these instruments, a movable pointer being fixed at the point at which the mercury is to be kept. Air or steam thermometers (see PYROMETER) are rapidly superseding mercury instruments for all temperatures above the boiling point of water. The cheap German paper-scale thermometers are largely used, fitted in wooden cases, as dairy thermometers, and a larger size for brewing purposes. Alarm thermometers are often employed, in which electric contact is made and a bell rung when the temperature exceeds or falls short of a certain limit. Thermostats of various forms are made use of, in which a thermometer, by the position of the mercury in the stem, regulates the gas supply of a burner and thus the heat of an enclosure.

Metallic Thermometers.—Thermometers depending on change in length or form of composite metal bars, such as Crighton's zinc-iron bar and Bréguet's silver-gold-platinum spiral (see PYROMETER), are converted into registering instruments by the addition of two light pointers pushed forward by the index needle as it travels round the graduated arc to either side and left at their extreme points. Jürgensen in 1841 constructed a chronometer, the balance wheel of which was arranged so as to exaggerate the effects of change of temperature and thus to affect the rate. It furnished a very close approximation to the mean temperature between the intervals of rating, and was approved by Arago for use in observations. Hermann and Pfister's metallic thermometer[8] is probably the best adapted for meteorological purposes, and has given satisfactory results at the Zurich observatory. It is a flat spiral of brass and steel, which unrolls and coils up according to changes of temperature, moving an index on a divided horizontal circle and marking the maximum and minimum by light pointers. In order to secure regular results, the instrument must be annealed by heating for some time in boiling linseed oil.

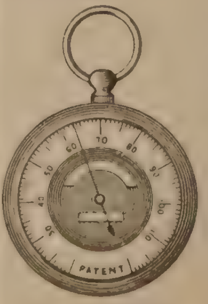

FIG. 9.—Immisch's Avitreous Thermometer.

Several instruments known popularly as metallic thermometers depend on a different principle, that of the change of form in a thin metallic enclosure containing liquid. Immisch's avitreous thermometer (Fig. 9) is an example. A minute Bourdon's tube is fixed at one end, and the other bears on the short arm of a lever, the long arm of which acts by a rack on the pinion forming the axis of the pointer. It is only one inch in diameter and extremely accurate.

Thermographs.—The first form of thermograph, due to Wheatstone, was an electrical apparatus. It has recently been improved by Van Rysselberghe, in whose hands it has assumed the following form. The thermometer is of rather wide bore and open above. At intervals of quarter of an hour a wire is moved gradually down the tube by a clock until it touches the mercury; an electric circuit is thus completed, and causes an indentation by a diamond point which moves in the same way as the wire down a rotating cylinder covered with thin sheet copper or zinc. The metal sheet is renewed at each revolution of the cylinder, and it is sufficient to join the indented points with a graver to have a plate from which any number of copies of the record may be printed. Cripp's thermograph records hourly on a revolving cylinder. It consists essentially of a mercury thermometer coiled into a flat spiral and suspended on a horizontal axis. Any change of temperature displaces the centre of gravity of the system, and the instrument rotates through an arc, moving a pencil as it does so. A perfectly continuous record is produced by the photographic thermograph. Wet and dry bulb thermometers are so arranged that a beam of light passes through an air-speck, which separates part of the mercury thread, or through the vacant part of the tube, and falls on a rotating cylinder covered with photographic paper on which it traces the curve of temperature fluctuation. This apparatus is probably the most perfect of its kind. In Bowkett's thermograph the change of form of a curved tube containing oil moves a pencil radially over a card turned horizontally by a clock. The resulting curve is referable to polar instead of rectangular co-ordinates; the radius measures temperature, the angle time. Richard's thermograph is also actuated by means of a sealed metallic capsule containing fluid. It draws a continuous curve in ink on a revolving drum on which one sheet lasts for seven days. This instrument is largely employed in observatories to check eye-observations, and is peculiarly adapted for use in positions to which access can only be had occasionally. It is made in many forms, one of which is specially adapted for marine work, the sealed capsule being rolled into the form of a cylinder and exposed to the water on both surfaces. (H. R. M.)

THÉROIGNE DE MÉRICOURT, ANNE JOSEPH (1762–1817), was born at Marcourt (from a corruption of which name she took her usual designation), a small town in Luxembourg, on the banks of the Ourthe, on 13th August, 1762. She was the daughter of a well-to-do farmer, Peter Théroigne. She appears to have been well educated, having been brought up in the convent of Robermont; she was quick-witted, strikingly handsome in appearance, and intensely passionate in temper; and she had a strong and almost volcanic power of eloquence, which she used with great effect upon the mobs of Paris during that short space of her life (1789–93) which alone is of historical interest. The story of her having been betrayed by a young *seigneur*, and having in consequence devoted her life to avenge her wrongs upon aristocrats, a story which is told by Lamartine and others, is unfounded, the truth being that she left her home on account of a quarrel with her stepmother. She went to Paris, and, on the outbreak of the Revolution, she was surrounded by a coterie of well-known men, chief of whom were Pétion and Desmoulins. She belonged to their party to the last,—became in fact the "Fury of the Gironde." On 14th July, 1789, she came prominently into notice at the fall of the Bastille, and for about four years thereafter she was seen in many of the stormiest scenes of the Revolution, being known as "la belle Liégoise," and singularly attired in a riding habit, a plume in her hat, pistols in her belt, and a sword dangling by her side. Early in October she took a leading part in the march to Versailles, and the return journey with the king and queen to the capital. No horror appalled her, and the violence of her language and her power with the mob were no less remarkable than the influence which she was able, by combining cajolery, threats, and money, successfully to exert on the royalist soldiers, so winning them over to the Revolution. Being justly accused of dangerous conduct, her arrest was ordered in the following year (1790), and she left Paris for Marcourt, whence after a short stay she proceeded to Liége, in which town she was seized by warrant of the Austrian Government, and conveyed first to Tyrol and thereafter to Vienna, accused of having been engaged in a plot against the life of the queen of France. After an interview, however, with Leopold II., she was released; and she returned to Paris, crowned of course with fresh laurels because of her captivity, and resumed her influence. In the clubs of Paris her voice was often heard, and even in the National Assembly she would violently interrupt the expression of any moderatist views. She commanded in person the 3d corps of the so-called army of the faubourgs on 20th June, 1792, and again won the gratitude of the people. She shares a heavy responsibility for her connexion with the riots of the 10th of August. A certain contributor to Desmoulins's journal, the *Acts of the Apostles*, Suleau by name, earned her savage hatred by associating her name, for the sake of the play upon the word, with a deputy named Populus, whom she had never seen. On the 10th of August, just after she had watched approvingly the massacre of certain of the national guard in the Place Vendôme, Suleau was pointed out to her. She sprang at him, dragged him among the infuriated mob, and he was stabbed to death in an instant. But the time came when her party was in peril at the hands of one more extreme, and she now wildly urged the mob to more moderate courses. Then the furies of the "Mountain" seized the fury of the Gironde, and they stripped her naked, and flogged her in the public garden of the Tuileries. The infamous affront drove her mad. She was removed to a private house, thence in 1800 to La Salpetrière for a month, and thence to a place of confinement called the Petites Maisons, where she remained—a raving maniac—till 1807. She was then again removed to La Salpetrière, where she died, never having recovered her reason, on 9th June, 1817.

THESEUS, the great hero of Attic legend,[1] son of Ægeus, king of Athens, and Æthra, daughter of Pittheus, king of Trœzen. Thus through his father he was descended from Erechtheus and the autochthones of Attica; through his mother he came of the Asiatic house of Pelops. Ægeus, being childless went to Delphi to consult the god, who gave him an ambiguous answer. He went to Trœzen, and told the oracle to Pittheus, who, seeing its bearing, contrived that Ægeus should have intercourse with his daughter Æthra. Ægeus then departed to Athens, and in due time Æthra, who remained at Trœzen, brought forth Theseus. It was given out that the child's father was Poseidon, the great god of Trœzen, and in after ages the Trœzenians pointed to the Holy Isle as the place where Poseidon and Æthra met, and where Æthra raised a temple to Athene Apaturia, at which Trœzenian maids dedicated their girdles before marriage. For his tutor and guardian young Theseus had one Cannidas, to whom, down to Plutarch's time, the Athenians were wont to sacrifice a black ram on the eve of the festival of Theseus. On passing out of boyhood, Theseus, in accordance with custom, went to Delphi, and there cut off his front hair. Ægeus had deposited his sword and boots under a heavy rock, telling Æthra that, if she gave birth to a son who, on attaining manhood, should be able to lift the rock and remove the sword and boots, she was to send him with all secrecy to his father at Athens. Theseus now lifted the rock, removed the sword and boots, and set out for Athens. He encountered many adventures on the way. First he met Periphetes, surnamed Corynetes (Clubman). Him Theseus slew, and carried off his club. At the isthmus of Corinth dwelt Sinis, called the Pine-Bender, because he killed his victims by fastening them to the top of a pine tree (or two pine-trees), which he had bent down and then suffered to fly up. Theseus hoisted the Pine-Bender on his own pine-tree. Now, the deceased Pine-Bender had a pretty daughter, who ran and hid herself in a thicket where asparagus grew plentifully and, when Theseus came to look for her, she prayed to the asparagus, and promised that if it would hide her she would never injure asparagus any more. Theseus wiled her from the thicket, and from their union sprang the family of the Ioxids, who worshipped asparagus. Next

---

[1] All the passages in the *Iliad* and *Odyssey* in which his name or allusions to his legend occur are regarded with more or less probability as spurious.

Theseus despatched the Crommyonian sow (or boar), a dreadful monster. Then he flung over the cliff the wicked Sciron, who, while his guests were perforce washing his feet, used to kick them over into the sea. In Eleusis, Theseus wrestled with and killed Cercyon. A little farther on he slew Procrustes, who had only one bed for all comers: if his guest was too short for the bed, he stretched him out; if he was too long, he cut him down to the requisite length. At the Cephissus Theseus was met by the Phytalid family, who purified him from the taint of bloodshed. As he passed through the streets of Athens, his curls and long garment reaching to his ankles drew on him the derision of some masons, who were putting on the roof of the new temple of Apollo Delphinius: "Why," they asked, "was such a pretty girl out alone?" In reply Theseus took the bullocks out of their cart and flung them higher than the roof of the temple. He found his father married to Medea, who had fled from Corinth. Being a witch, she knew Theseus before his father did, and tried to persuade Ægeus to poison his son; but Ægeus at last recognized him by his sword, and took him to his arms. Theseus was now declared heir to the throne, and the Pallantids, who had hoped to succeed to the childless king, conspired against Theseus, but he crushed the conspiracy. He then attacked the flame-spitting bull of Marathon and brought it alive to Athens, where he sacrificed it to Apollo Delphinius. Now comes the adventure of the Cretan Minotaur (see MINOS), whom Theseus slew by the aid of ARIADNE (*q.v.*). While Theseus was in Crete, Minos, wishing to see whether Theseus was really the son of Poseidon, flung his ring into the sea. Theseus dived and brought it up, together with a golden crown, the gift of Amphitrite. On the return voyage the ship touched at Naxos, and there Theseus abandoned Ariadne. He landed also at Delos, and there he and the youths danced the crane dance, the complicated movements of which were meant to imitate the windings of the Labyrinth.[1] In historical times this dance was still danced by the Delians round the horned altar—an altar entirely composed of left-sided horns. Theseus had promised Ægeus that, if he returned successful, the black sail with which the fatal ship always put to sea[2] should be exchanged for a white one. But he forgot his promise; and, when from the Acropolis at Athens Ægeus descried the black sail out at sea, he flung himself from the rock, and died. Hence at the festival which commemorated the return of Theseus there was always weeping and lamentation. Theseus now carried out a political revolution in Attica by abolishing the semi-independent powers of the separate townships and concentrating those powers at Athens, and he instituted the festival of the Panathenæa,[3] as a symbol of the unity of the Attic race. Further, according to a democratic tradition, he abolished the monarchy, and substituted in its place a popular government; but to obviate the evils of a pure democracy, he instituted the three classes or castes of the eupatrids (nobles), geomori (husbandmen), and demiurgi (artisans). He also minted coins bearing the figure of an ox. He extended the territory of Attica as far as the isthmus of Corinth.

He was the first to celebrate in their full pomp the Isthmian games in honor of Poseidon; for the games previously instituted by Hercules in honor of Melicertes had been celebrated by night, and had partaken of the nature of mysteries rather than of a festival. Of Theseus's adventures with the Amazons there were different accounts. According to some, he sailed with Hercules to the Euxine, and there won the Amazon Antiope as the meed of valor; others said that he sailed on his own account, and captured Antiope by stratagem. Thereafter the Amazons attacked Athens. Antiope fell fighting on the side of Theseus, and her tomb was pointed out on the south side of the acropolis. By Antiope Theseus had a son, Hippolytus. On the death of Antiope, Theseus married Phædra. She fell in love with her stepson Hippolytus, who resisting her advances, was accused by her to Theseus of having attempted her virtue. Theseus in a rage imprecated on his son the wrath of Poseidon. His prayer was answered: as Hippolytus was driving beside the sea, a bull issuing from the waves terrified his horses, and he was thrown and killed. This tragic story is the subject of one of the extant plays of Euripides.

The famous friendship between Theseus and Pirithous king of the Lapiths, originated thus. Hearing of the strength and courage of Theseus, Pirithous desired to put them to the test. Accordingly he drove away from Marathon some cows which belonged to Theseus. The latter pursued, but, when he came up with the robber, the two heroes were so filled with admiration of each other that they swore brotherhood. At the marriage of Pirithous to Hippodamia (or Deidamia) a fight broke out between the Lapiths and Centaurs, in which the Lapiths, assisted by Theseus, were victorious, and drove the Centaurs out of the country. Theseus and Pirithous now carried off Helen from Sparta, and when they drew lots for her she fell to the lot of Theseus, who took her to Aphidnæ, and left her in charge of his mother Æthra and his friend Aphidnus. He now descended to the lower world with Pirithous, to help his friend to carry off Proserpine. But the two were caught and confined in Hades till Hercules came and released Theseus. Meantime Castor and Pollux had captured Aphidnæ, and carried off their sister Helen and Æthra. When Theseus returned to Athens, he found that a sedition had been stirred up by Menestheus, a descendant of Erechtheus, one of the old kings of Athens. Failing to quell the outbreak, Theseus in despair sent his children to Eubœa, and, after solemnly cursing the Athenians, sailed away to the island of Scyrus, where he had ancestral estates. But Lycomedes, king of Scyrus, took him up to a high place, and cast him into the sea, that he died. Others said that he fell off himself over the cliff as he was taking his evening walk. Menestheus reigned at Athens, but, when he died before Troy, the sons of Theseus recovered the kingdom. Long afterwards, at the battle of Marathon (490 B.C.), many of the Athenians thought they saw the phantom of Theseus, in full armor, charging at their head against the Persians. When the Persian war was over, the Delphic oracle bade the Athenians fetch the bones of Theseus from Scyrus, and lay them in Attic earth. It fell to Cimon's lot in 469 B.C. to discover the hero's grave at Scyrus, and bring back his bones to Athens. They were deposited in the heart of Athens, and henceforth escaped slaves and all persons in peril sought and found sanctuary at the grave of him who in his life had been a champion of the oppressed. His chief festival was on the 8th of the month Pyanepsion (October 21st), but the 8th day of every month was also sacred to him.

Whatever we may think of the historical reality of Theseus, his legend seems to contain recollections of historical events, *e.g.*, the συνοικισμός, whether by this we understand the political centralization of Attica at Athens or a local union of previously separate settlements on the site of Athens. The birth of Theseus at Trœzen points to the immigration of an Ionian family or tribe from the south. With this agrees the legend of the contest between Athene and Poseidon for supremacy on the acropolis of Athens, for Theseus is intimately connected with Poseidon, the great Ionian god. Ægeus, the father of Theseus, has been identified by some modern scholars with Poseidon.

---

[1] The Ostiaks of Siberia have an elaborate crane dance, in which the dancers are dressed up with skins and the heads of cranes (Pallas, *Reise durch verschiedene Provinzen des russischen Reichs*, iii. 65).

[2] So, too, the ship that sailed annually from Thessaly to Troy with offerings to the shade of Achilles put to sea with sable sails (Philostratus, *Heroica*, xx. 25). The ship that was to bring Iseult to the mortally wounded Tristram was to hoist a white sail if she was on board, a black sail if she was not. The black sails recur in the modern Greek version of the tale of Theseus. Compare *Asiatick Researches*, ix. 97.

[3] Besides the Panathenæa, Theseus is said to have instituted the festival of the *Synoikia* or *Metoikia*. Wachsmuth ingeniously supposes that the latter festival commemorated the local union in a single city of the separate settlements on the Acropolis and its immediate neighborhood, while the Panathenæa commemorated the political union of the whole of Attica (C. Wachsmuth *Die Stadt Athen im Alterthum*, p. 453 *sq.*

The Athenian festival in October, popularly supposed to commemorate the return of Theseus from Crete, is interesting, as some of its features are identical with those of harvest-festivals still observed in the north of Europe. Thus the *eiresione*, a branch of olive wreathed with wool and decked with fruits, bread, etc., which was carried in procession and hung over the door of the house, where it was kept for a year, is the *Erntemai* (Harvest-may) of Germany.[1]

The well-preserved Doric temple to the north of the acropolis at Athens, commonly known as the Theseum, was long supposed to be the sanctuary in which the bones of Theseus reposed. But archæologists are now much divided on this question. It is agreed, however, that the temple is of the 5th century B.C., and that the date of its construction cannot differ widely from that of the Parthenon.[2] There were several (according to Philochorus, four) temples or shrines of Theseus at Athens. Milchhöfer thinks he has found one of them in the neighborhood of Piræus.[3]

Our chief authority for the legend of Theseus is the life by Plutarch, which is a compilation from earlier writers. G. Gilbert, who has investigated the sources from which Plutarch drew for his life of Theseus, believes that his chief authority was the *Atthis* of Ister, and that Ister mainly followed Philochorus. See *Philologus*, xxxiii., 1874, p. 46 *sq.*

There is a modern Greek folk-tale which preserves some features of the legend of Theseus and the Minotaur, but for the Minotaur has been substituted a seven-headed snake. See Bernard Schmidt, *Griechische Mährchen, Sagen, und Volkslieder*, p. 118 *sq.* (J. G. FR.)

THESMOPHORIA, an ancient Greek festival, celebrated by women only in honor of Demeter Θεσμοφόρος. At Athens, Abdera, and perhaps Sparta, it lasted three days. At Athens the festival took place on the 11th, 12th, and 13th of the month Pyanepsion (24th, 25th, and 26th October), the first day being called Anodos (ascent), or, according to others, Kathodos (descent), the second Nesteia (fast), and the third Kalligeneia (fairborn).[4] If to these days we add the Thesmophoria, which were celebrated on the 10th at Halimus, a township on the coast near Athens, the festival lasted four days.[5] If further we add the festival of the Stenia, which took place on the 9th, the whole festival lasted five days.[6] The Stenia are said by Photius to have celebrated the return of Demeter from the lower world (Anodos), and the women railed at each other by night.[7] The Thesmophoria at Halimus seem to have included dances on the beach.[8] The great feature of the next day (the Anodos) is generally assumed to have been a procession from Halimus to Athens, but this assumption seems to rest entirely on an interpretation of the name Anodos, and it loses all probability when we observe that the day was by others called Kathodos.[9] Probably both names referred to the descent of Demeter or Proserpine to the nether world, and her ascent from it.[10] The next day, Nesteia, was a day of sorrow, the women sitting on the ground and fasting.[11] As to what took place on the Kalligeneia we have no information. Nor can we define the time or nature of the secret ceremony called the "pursuit" or the "Chalcidian pursuit," and the sacrifice called the "penalty."[12]

During the Thesmophoria (and for nine days previously, if Ovid, *Met.*, x. 434, is right, and refers to the Thesmophoria) the women abstained from intercourse with their husbands, and to fortify themselves strewed their beds with *Agnus castus* and other plants. The women of Miletus strewed their beds with pine branches, and put fir-cones in the sanctuaries of Demeter.[13] Whether unmarried women were admitted to the festival seems doubtful; in Lucian's time it would appear that they were.[14] The women of each deme (township) elected two married women of their number to preside over them at the festival; and every married man in the township who possessed property to the value of three talents had to provide a feast for the women on behalf of his wife.[15] During the festival the women seem to have been lodged by twos in tents or huts, probably erected within the sacred precincts of the Thesmophorium.[16] They were not allowed to eat the seeds of the pomegranate or to wear garlands of flowers.[17] Prisoners were released at the festival,[18] and during the Nesteia the law-courts were closed and the senate did not meet.[19] Aristophanes's play on the festival sheds little light on the mode of its celebration.

At Thebes Thesmophoria were celebrated in summer on the acropolis (Cadmeia); at Eretria during the Thesmophoria the women cooked their meat, not at fires, but by the heat of the sun, and they did not invoke Kalligeneia (which seems to mean that they did not celebrate the last day of the festival); at Syracuse, during the festival, cakes called *mylloi*, made of sesame and honey in the shape of *pudenda muliebria*, were handed round.[20] Agrigentum, Ephesus, and Dryme, in Phocis, had also their Thesmophoria.[21]

The above was nearly all that was known about the Thesmophoria down to 1870. In that year E. Rohde published in the *Rheinisches Museum* (N. F. 25, p. 548 *sq.*) a scholion on Lucian (*Dial. Meretr.*, ii. 1), which he discovered in the Vatican MS. Palatinus 73, and which furnishes some curious details about the Thesmophoria. It also explains two obscure and corrupt passages of Clemens Alexandrinus and

[3] See *Erläuternder Text* to the *Karten von Attika* (Berlin, 1881), i. p. 37 *sq.*

[4] Schol. on Aristoph., *Thesmophoriazusæ*, 80 and 585; Diog. Laer., ix. 43; Hesychius, s.v. τριήμερος (the reading here is uncertain) and ἄνοδος; Alciphron, iii. 39; Athenæus, 307*f.* Plutarch (*Vit. Demosth.*, 30) states that the Nesteia took place on the 16th of Pyanepsion, but in this he stands alone.

[5] Schol. on Aristoph., *Thesm.*, 80; Photius, *Lex.*, s.v. Θεσμοφορίων ἡμέραι δ′ (where Naber should not have altered the MS. reading δ′ into ιδ′); Hesychius, s.v. τρίτη Θεσμοφορίων.

[6] Schol. on Aristoph., *Thesm.*, 834.

[7] Photius, *Lex.*, s.v. στήνια; *cf.* Apollodorus, i. 5, 1.

[8] Plut., *Solon*, 8; for this passage probably refers to the Thesmophoria, the Cape Colias mentioned being near Halimus (see *Erläuternder Text* to the *Karten von Attika*, ii. 1 *sq.*). The Thesmophorium at Halimus is mentioned by Pausanias (i. 31, 1).

[9] Hesychius (s.v. ἄνοδος) and the Schol. on Arist., *Thesm.*, 585, suppose that the day was so called because the women ascended to the Thesmophorium, which (according to the scholiast) stood on a height. But no ancient writer mentions a procession from Halimus. For the name *Kathodos*, see Schol., *loc. cit.*; Photius, *Lex.*, s.v. Θεσμοφορίων ἡμέραι δ′. For the statement that at one part of the festival (commonly assumed, by the writers who accept the statement, to be the Anodos) the women carried on their heads the "books of the law," we have only the authority of the scholiast on Theocritus, iv. 25, who displays his ignorance by describing the women as virgins (see below), and saying that they went in procession to Eleusis. The statement may therefore be dismissed as an etymological fiction. Aristophanes, *Eccles.*, 222, is no evidence for the book-carrying.

[10] The Bœotian festival of Demeter, which was held at about the same time as the Athenian Thesmophoria, and at which the *megara* (see below) were opened, is distinctly stated by Plutarch (*De Is. et Osir.*, 69) to have been a mourning for the descent (Kathodos) of Proserpine.

[11] Plut., *Dem.*, 30; Id., *De Is. et Osir.*, 69.

[19] Aristoph., *Thesm.*, 80. The word τρίτη seems to mean the Nesteia, as the Schol. *ad l.* takes it. That the "middle day" was the Nesteia we know from Athenæus, 307*f.*

[20] Xenophon, *Hellen*, v. 2, 29; Plutarch, *Quæst. Gr.*, 31; Athenæus, 647*a*.

[21] Polyænus, v. 1, 1; Herodotus, vi. 16; Pausanias, x. 33, 12.

Pausanias, the true meaning of which had been divined by Lobeck (*Aglaophamus*, p. 828 *sq.*). The substance of the scholion is this. When Proserpine was carried off by Pluto, a swineherd called Eubuleus was herding his swine at the spot, and his herd was engulfed in the chasm down which Pluto had vanished with Proserpine. Accordingly at the Thesmophoria it was customary, in memory of Eubuleus, to fling pigs into the "chasms of Demeter and Proserpine." (These "chasms" may have been natural caverns or perhaps vaults. The scholiast speaks of them also as *adyta* and *megara*.[1]) In these chasms or adyta there were supposed to be serpents, which guarded the adyta and consumed most of the flesh of the pigs that were thrown in. The decayed remains of the flesh were afterwards fetched by women called "drawers" (*antletriai*), who, after observing rules of ceremonial purity for three days, descended into the caverns, and, frightening away the serpents by clapping their hands, brought up the remains and placed them on the altars.[2] Whoever got a portion of this decayed flesh and sowed it with the seed in the ground was supposed thereby to secure a good crop.[3] The rest of the scholion is obscure, and perhaps corrupt, but the following seems to be the sense. The ceremony above described was called the arretophoria, and was supposed to exercise the same quickening and fertilizing influence on men as on fields. Further, along with the pigs, sacred cakes made of dough, in the shape of serpents and of phalli, were cast into the caverns, to symbolize the productivity of the earth and of man. Branches of pines were thrown in[4] for a similar reason.

The custom described in this important scholion is clearly the same as that referred to by Clemens Alexandrinus (*Protrep.*, § 17) and Pausanias (ix. 8, 1). From the latter we learn that the pigs were sucking pigs, and from the former (if we adopt Lobeck's emendation μεγάροις ζῶντας for μεγαρίζοντες) that they were thrown in alive. From Pausanias we may further perhaps infer (though the passage is corrupt) that the remains of the pigs thrown down in one year were not fetched up till the same time next year (cp. Paus., x. 32, 14). The question remains, At what point of the Thesmophoria did the ceremony described by the scholiast on Lucian take place? Rohde thinks that it formed part of the ceremonies at Halimus, his chief ground being that Clemens (*Protrep.*, 34) and Arnobius (v. 28) mention phalli in connection with the "mysteries at Halimus"; but it is not certain that these mysteries were the Thesmophoria. The legend of Eubuleus seems to show that the ceremony commemorated the descent of Proserpine to the nether world; and, if we are right in our interpretation of the name Kathodos as applied to the first day of the Thesmophoria proper, the ceremony described would naturally fall on that day. Further, if our interpretation of Pausanias is correct, the same day must have witnessed the descent of the living pigs and the ascent of the rotten pork of the previous year. Hence the day might be indifferently styled Kathodos or Anodos ("descent" or "ascent"); and so in fact it was.

It is usual to interpret Thesmophorus "lawgiver" and Thesmophoria "the feast of the lawgiver." But the Greek for "lawgiver" is not Thesmophorus but Thesmothetes (or Nomothetes, when *nomos* displaced *thesmos* in the sense of "law"). If we compare such names of festivals as Oschophoria, Lampadephoria, Hydrophoria, Scirophoria ("the carrying of grapes, of torches, of water, of umbrellas") with the corresponding Oschophorus, Lampadephorus, Hydrophorus, also Thallophorus and Kanephorus, we can scarcely help concluding that Thesmophoria must originally have meant in the literal and physical sense the carrying of the *thesmoi*, and Thesmophorus the person who so carried them; and, in view of the ceremony disclosed by the scholiast on Lucian (compared with the analogous ceremony observed by the Arrephoroi at Athens, we are strongly tempted to suppose that the women whom he calls Antletriai may have been also known, at one time or other, as Thesmophoroi, and that the *thesmoi* were the sacra which they carried and deposited on the altar. The word would then be used in its literal sense, "that which is set down." How the name Thesmophorus should have been transferred to the goddess from her ministers is of course a difficulty, which is hardly disposed of by pointing to the epithets Amallophorus ("sheaf-bearing") and Melophorus ("apple-bearing"), which were applied to men as well as to the goddess.

As to the origin of the Thesmophoria, Herodotus (ii. 171) asserts that they were introduced into Greece from Egypt by the daughters of Danaus; while, according to Plutarch (*Fragments*, p. 55, ed. Dübner), the feast was introduced into Athens by Orpheus the Odrysian. From these statements we can only infer the similarity of the Thesmophoria to the Orphic rites and to the Egyptian representation of the sufferings of Osiris, in connection with which Plutarch mentions them. The Thesmophoria would thus form one of that class of rites, widely spread in Western Asia and in Europe, in which the main feature appears to be a lamentation for the annual decay of vegetation or a rejoicing at its revival. This seems to have been the root, *e.g.*, of the lamentations for Adonis and Attis. See W. Mannhardt, *Antike Wald- und Feld-Kulte*, p. 264 *sq.*

THESPIÆ, an ancient Greek city of Bœotia. It stood on level ground commanded by the low range of hills which runs eastward from the foot of Mount Helicon to Thebes. In the Persian invasion the Thespian contingent of 700 men voluntarily stayed with the Spartans at Thermopylæ, and shared their fate. For its resistance to the Persians, the city was burned by Xerxes (480 B.C.). Nevertheless, in the next year 1800 Thespians shared in the great victory of Platæa. At the battle of Delium (424) the flower of the Thespians fell fighting against Athens on the side of Thebes, and in the following year the jealous Thebans availed themselves of the weakness of their gallant confederate to pull down the walls of Thespiæ. The walls were restored by the Spartans under Agesilaus in 378, but were again destroyed by the Thebans, apparently before the battle of Leuctra (371).[5] After the battle the Thespians, who had taken no part in it, withdrew to a strong place, Ceressus, from which, however, they were expelled by the Thebans. In 343 the city was not yet restored; but it must have been subsequently, for it is mentioned in the Roman wars.

In the 2d century Pausanias mentions that Thespiæ contained a theatre, a market-place (*agora*), and sanctuaries of Aphrodite, the Muses, and Hercules. Love (Eros) was the deity most venerated by the Thespians; they possessed a very ancient image of him in the shape of an unhewn block of stone. The marble statue of Love by Praxiteles was the great sight at Thespiæ, and drew crowds to the place. It was carried off to Rome by Caligula, restored by Claudius, and again carried off by Nero. There was also a bronze statue of Love by Lysippus. From an inscription we learn that one of the deities worshipped was Demeter Achea, the "Mater Dolorosa." The Thespians also worshipped the Muses, and celebrated a festival in their honor in the sacred grove on Mount Helicon. Remains of what was probably the ancient cidadel are still to be seen, consisting of an oblong or oval line of fortification, solidly and regularly built. The adjacent ground to the east and south is covered with foundations, bearing witness to the extent of the ancient city. The neighboring village Eremokastro, on higher ground, was thought by Ulrichs to be probably the site of the ancient Ceressus. In 1882 there were discovered, about 1200 yards east of Eremokastro, on the road to Arkopodi (Leuctra), the remains of a *polyandrion*, including a colossal stone lion. The tomb dates from the 5th century B.C., and is probably that of the Thespians who fell at Platæa, for those who fell at Thermopylæ were buried on the field.

---

[1] Mr. C. T. Newton discovered in the sanctuary of Demeter and the Infernal Deities at Cnidus a chamber which may have been one of the *megara* referred to by the scholiast. It contained bones of pigs and marble figures of pigs. The chamber was not, however, originally subterranean. See Newton's *Discoveries at Halicarnassus, etc.*, ii. p. 383 *sq.*; Id., *Travels and Discoveries in the Levant*, ii. p. 180 *sq.* According to Porphyry (*De Andro Nympharum*, 6) the Infernal Deities had *megara*, as the Olympian had temples, and the sacrificial pits of the former corresponded to the altars of the latter.

[2] Compare the functions of the two Arrephoroi at Athens (Paus., i. 27, 3). For serpents in connection with Demeter, compare Strabo, ix. 1, 9.

[3] This, as Mr. Andrew Lang has pointed out, resembles the Khond custom of burying the flesh of the human victim in the fields to fertilize them. The human victim was with the Khonds, like the pig with the Greeks, a sacrifice to the Earth goddess. See W. Macpherson, *Memorials of Service in India*, p. 129.

[4] Reading ἐμβάλλουσι, with Rohde, for λαμβάνουσι. Compare the custom of Miletus *supra*. The pine-tree played an important part in the worship of Cybele. Cp. Marquardt, *Staatsverwaltung*, iii. 371.

[5] Xenophon (*Hellen.*, vi. 3, 1 and 5) and Diodorus (xv. 46) speak of Thespiæ as if it had been destroyed and its inhabitants driven away before the battle of Leuctra; but, as the Thespian troops were present with the Thebans immediately before the battle (Paus., ix. 13, 8), it would seem that only the walls, not the city itself, had been previously destroyed. See Grote, *Hist. of Greece*, ix. p. 379.

THESSALONIANS, Epistles to the. Thessalonica, now Salonica (*q.v.*), was in the time of the Romans the most important town of Macedonia. In consequence of its advantageous situation, on a good harbor and on the Via Egnatia, the great trade road which connected the Adriatic with the Hellespont, the town had surpassed the old capital Pella, and had indeed become one of the chief commercial centres of the ancient world. Since the Roman conquest the seat of the Roman provincial government had been here. Here, as in Corinth, the conditions were favorable for the reception of Christianity. The population was not purely Greek, but cosmopolitan, a mixture of divers nationalities. Such a population is always more susceptible to religious novelties for good and for evil than one of old, firmly established national growth. The apostle Paul experienced this to his great joy and satisfaction here also, as he for the first time set foot on the shores of Europe with the message of Jesus Christ. It was about the year 52 or 53 that he, on his arrival from Philippi, preached the gospel of Christ in the rich merchant city. As in other places, he began with the Jews. There was a Jewish congregation at Thessalonica, as at all the great ports and trading centres of the Mediterranean, with their own synagogue and regular service. For three Sabbaths Paul stood up in the synagogue, proving by the Scriptures that Jesus was the promised and expected Messiah (Acts xvii. 1–3). He had not much success with the Jews, but this was more than compensated by the number of "devout Greeks" (*i.e.*, Gentiles who already had some connection with Judaism) whom he won to a belief in Christ. He found hearing especially with the chief women (Acts xviii. 4). But Paul had also converted a not smaller number of real heathens. Indeed, they must have constituted the majority of the Christian church there formed, for in his first epistle he says quite generally that his readers, in consequence of his preaching, had turned from idols to the one true God (1 Thess. i. 9).

Paul's stay in Thessalonica was short. The plots of the Jews soon obliged him to leave the town, and he betook himself to Berœa. (Acts xvii. 10), thence to Athens (Acts xvii. 15), and finally to Corinth (Acts xviii. 1). The two epistles were written to the church of Thessalonica during a stay of a year and a half in Corinth (Acts xviii. 11), about 53–54, not before this in Athens, as is asserted in the subscription of both epistles in the Codex Alexandrinus and other MSS. For when Paul wrote the first epistle some time had elapsed since the formation of the church: some members were already dead (1 Thess. iv. 13), and Paul had worked for some time, not only in Macedonia, but also in Achaia (i. 7, 8). On the other hand, the church appears to be comparatively young; the conversions are still spoken of everywhere in Macedonia and Achaia (i. 9). All this points to the conclusion that the first epistle was written in Corinth, and this is confirmed by the opening salutation (i. 1), in which Silvanus (Silas) and Timotheus are named as joint authors, for they were in Corinth with Paul (Acts xviii. 5).

The first epistle gives us a very clear picture of the disposition and state of such a young church, composed of former heathens. They had received with enthusiasm the gospel of Jesus Christ, the Bringer of salvation, the Saviour in the approaching day of judgment (i. 9, 10). But the realization of this salvation is now awaited with impatience, and a sense of disappointment is experienced because some members of the church have died without having seen the advent of the Lord (iv. 13). At the same time many there are still living in gross heathen sins and vices (iv. 1–8). Paul had sent back Timotheus from Athens to Thessalonica in order to advise the young inexperienced church, and to obtain news concerning it (iii. 1–5). He has just returned to Paul (iii. 6), and the information received through this source is the occasion of the first epistle,[1] designed to supply the place of Paul's personal presence and bring new exhortation and instruction from the apostle to the young church, which still much needed guidance.

We have no information concerning the effect of this letter. It is conceivable, however, that the church required yet further advice and direction from the apostle, and so far it is not remarkable that Paul saw the need for a second similar letter of teaching and exhortation. This second epistle also, if it is genuine, was written during Paul's stay of a year and a half at Corinth, very soon after the first. For it also is written in the conjoined names of Silvanus and Timotheus, who were still with Paul, while we must understand from Acts xviii. 18 that after Paul's departure from Corinth they ceased to be his companions. The occasion of this epistle seems especially to have arisen from the circumstance that the church had been put into fear and anxiety about the advent of Christ, perhaps by a pretended letter from Paul. Two passages point to the existence of such a thing: in ii. 2, Paul says that the church shall not let itself be alarmed "by word or by letter as from us" (*i.e.*, nominally coming from us), and in iii. 17 again Paul lays emphasis on his signature by his own hand as the token (of genuineness) to be noticed in each letter. In any case the chief aim of the epistle is to tranquillize the church concerning the advent of Christ, which is not yet immediately imminent. He particularly exhorts them not to let themselves be shaken in mind, as that the day of Christ is at hand (ii. 1, 2). For before this day comes the "man of sin" must first appear, who seats himself in the temple of God, and gives himself out for God (ii. 3–5). And he too is for the present kept back by another power (ii. 6, 7). Only when the latter is taken out of the way shall "that wicked" be revealed, and the great falling away shall follow (ii. 8–12).

The genuineness of the two epistles has not remained unquestioned by the newer criticism. Baur declared himself against the genuineness of both epistles,[2] and he is followed by Van der Vies[3] and several others.[4] But in general the predominant opinion of impartial criticism at present is that the genuineness of the first epistle is certain, while that of the second must be given up.

This is the opinion of Hilgenfeld (*Z. f. wiss. Theol.*, 1862, p. 225–264; 1866, p. 295–301; 1869, p. 441 *sq.*; 1870, p. 244 *sq.*), Van Manen (*Onderzoek naar de echtheid van Paulus tweeden brief aan de Thessalonicensen*, Utrecht, 1865), S. Davidson (*Introd. to the New Testament*, 2d ed., 1882, i. 4–16, 336–351), Weizsäcker (*Das apostolische Zeitalter*, 1886, p. 249–261); and Holtzmann also leans to the same view, without, however, definitely committing himself (*Einl. in d. N. T.*, 2d ed., 1886, p. 233–241). The genuineness of the first epistle is vindicated by Lipsius (*Theol. St. u. Kr.*, 1854, p. 905–934), Von Soden (*ibid.*, 1885, p. 263–310), and Paul Schmidt (*Der erste Thessalonicherbrief neu erklärt*, Berlin, 1885), while, on the other hand, Kern (*Tübing. Zeitschr. f. Theol.*, 1839, ii. 145–214) and Bahnsen (*Jahrb. für prot. Theol.*, 1880, p. 681–705) attack that of the second. Grimm (*Theol. St. u. Kr.*, 1850, p. 753–816) and Westrik (*De echtheid van den tweeden brief aan de*

[1] According to Acts xvii. 14–15 and xviii. 5, Silas and Timotheus had remained behind in Berœa, and first met Paul again in Corinth. But according to 1 Thess. iii. 1–5 it must be understood that Timotheus was in Athens with Paul, and had been sent thence to Thessalonica.

[2] *Paulus der Apostel Jesu Christi*, 1845, and *Theologische Jahrbücher*, 1855, p. 141–168, reprinted in 2d ed. of *Paulus*, ii. 341–369.

[3] *De beide brieven aan de Thessalonicensen*, Leyden, 1865.

[4] Holsten also (*Jahrb. f. prot. Theol.*, 1877, p. 731 *sq.*) and Steck (*Jahrb. f. prot. Theol.*, 1883, p. 509–524) dispute the genuineness of the first epistle, presupposing the spuriousness of the second.

Thessalonicensen, Utrecht, 1879) have entered the lists for the genuineness of both epistles.

The final decision of the newer criticism is justified by the evidence. No real difficulties can be brought against the genuineness of the first epistle, but they certainly can against that of the second. When Baur finds that the epistles lack the characteristic Pauline ideas, he is only so far right that the doctrine of justification by faith is not dealt with, for which, however, no occasion arises. It has been asserted that there are traces of imitation of the epistles to the Corinthians, but the points of resemblance are not such as to justify this conclusion. The connection of the passage in 1 Thess. ii. 16 (the wrath of God is already come upon the Jews) with the destruction of Jerusalem rests on an arbitrary, nay false, interpretation. And it cannot be maintained on impartial examination that in 1 Thess. ii. 14, 15, the Jewish churches of Palestine are set forth in a way unlike Paul, as an example for the heathen churches.

The objections to the second epistle are much weightier, though here also not all the arguments adduced by hostile critics are valid. It has been often said that the author, like the author of the Apocalypse, regards Nero as the Antichrist, expecting him to reappear as the arch-enemy of Christ. But this interpretation of the short statement of our epistle cannot be proved. The assumption that before the dawn of salvation godlessness would reach its height through the appearance of an arch-enemy of God and His church is, so to speak, a dogmatic postulate which rests on the prophecies of Daniel and other prophets of the Old Testament. And, in so far as the picture of this arch-enemy is endowed with historical features, they can quite as well have been drawn from Caligula as from Nero. For Caligula had already laid claim to the honors of a god, and because of this appeared to the Jews to be the embodiment of godlessness. The assumption of such an Antichrist would not be striking in Paul. Even if it is correct (as is generally and with reason taken for granted) that by the hindrance which keeps back the appearance of Antichrist (2 Thess. ii. 6, 7) the established might of the Roman emperor and empire is to be understood, this view would be quite in keeping with Paul's views about the Roman dominion (Rom. xiii. 1–7). Yet it must be conceded that the statements on this head create real difficulty, if we compare them with those of the first epistle, in which all stress is laid on the fact that the day of the Lord comes as a thief in the night, and that man must be prepared for it at any moment (1 Thess. v. 1–11). In the second epistle it is pointed out with equal emphasis that the day of the Lord is not immediately imminent, and that certain events must come first (2 Thess. ii. 1–10). It is certainly very striking that Paul, so soon after the admonitions of the first kind, should have given the quieting assurances of the second. And 2 Thess. ii. 2 and iii. 7 can hardly be explained except by the supposition that the readers had been thrown into alarm by a pretended epistle from Paul. Could this have been dared in that early time, almost under the eyes of the apostle? Finally, it is not to be denied that the style of the second epistle is different from that of the first, and that the contents often appear a mere imitation, except in the eschatological passages on account of which it was written. It must therefore be admitted that weighty if not conclusive considerations have been produced against its genuineness. (E. S*.)

THESSALONICA. See SALONICA.

See vol. xi. Plates I. and II. and vol. xv. Pl. III.

THESSALY is the district of northern Greece which intervenes between Macedonia and the more purely Hellenic countries towards the south, and between the upland region of Epirus and the Ægean Sea. It forms an irregular square, extending for about sixty miles in each direction, and this area, which is for the most part level, is enclosed by well-marked boundaries—by the Cambunian Mountains on the north, and by Othrys on the south, while on its western side runs the massive chain of Pindus, which is the backbone of this part of Greece, and towards the east Ossa and Pelion stand in a continuous line; at the northeastern angle Olympus rises, and is the keystone of the whole mountain system. The elevation of some of the summits in these ranges is considerable, for three of the peaks of Pindus are over 5000 feet, and Olympus, Ossa, and Pelion reach respectively the height of 9754, 6407, and 5310 feet. The country that is contained within these limits is drained by a single river, the Peneius, which, together with the water of its numerous confluents, passes into the sea through the Vale of Tempe. This place, which the Greeks were accustomed to associate with rural delights, is a chasm, cloven in the rocks, as the fable tells us, by the trident of Poseidon, between Olympus and Ossa; but though it possesses every element of the sublime, yet its features are soft and beautiful, from the broad winding river, the luxuriant vegetation, and the glades that at intervals open out at the foot of the cliffs. It is about four miles and a half long, and towards the middle of the pass, where the rocks are highest, the precipices in the direction of Olympus fall so steeply as to bar the passage on that side; but those which descend from Ossa are the loftiest, for they rise in many places not less than 1500 feet from the valley. Owing to the length and narrowness of the ravine, it was a position easily defended, but still it offered a practicable entrance to an invading force, in consequence of which a number of castles were built at different times at the strongest points. On the north side of Thessaly there was an important pass from Petra in Pieria by the western side of Olympus, debouching on the plain northward of Larissa; it was by this that Xerxes entered, and we learn from Herodotus (vii. 173) that, when the Greeks discovered the existence of this passage, they gave up all thoughts of defending Tempe. On the side of Epirus the main line of communication passed over that part of Pindus which was called Mount Lacmon, and descended the upper valley of the Peneius to Æginium in the northwest angle of Thessaly, near which place now stand the extraordinary monasteries of Meteora. This was the route by which Julius Cæsar arrived before the battle of Pharsalia. Another pass through the Pindus chain was that of Gomphi, farther south, by means of which there was communication with the Ambracian Gulf. The great southern pass was that of Cœla, which crosses Mount Othrys nearly opposite Thermopylæ. These Thessalian passes were of the utmost importance to southern Greece, as commanding the approaches to that part of the country.

Though Thessaly is the most level district of Greece, it does not present a uniform unbroken surface, but is composed of a number of sections which open out into one another divided by ranges of hills. The principal of these were called Upper and Lower Thessaly, the former comprising the western and southwestern part, which contains the higher course of the Peneius and all those of its tributaries that flow from the south—the Enipeus, the Apidanus, the Onochonus, and the Pamisus; while the latter which reaches eastward to the foot of Ossa and Pelion, is inundated in parts at certain seasons of the year by the Peneius, the flood-water from which forms the lake Nessonis, and, when that is full, escapes again and pours itself into the Lake of Bœbe. The chief city of the latter of these districts was Larissa; and the two were separated from one another by a long spur, which runs southwards from the Cambunian Mountains on the western side of that city. Again, when Thessaly is entered from the south by the pass of Cœla, another plain, containing a small lake, which was formerly called Xynias, intervenes, and a line of low hills has to be crossed before the town of Thaumaci is reached, which from its commanding position overlooks the whole of the upper plain. The view from this point has been described by Livy in the following remarkable passage: "When the traveller, in passing through the rugged districts of Thessaly, where the roads are entangled in the windings of the valleys, arrives at this city, on a sudden an immense level expanse, resembling a vast sea, is outspread before him in such a manner that the eye cannot easily reach the limit of the plains extended beneath" (xxxii. 4). To the northeastwards of this, where a portion of the great plain begins to run up into the mountains, the Plain of Pharsalia is formed, which is intersected by the river Enipeus; and still farther in the same direction is the scene of another great battle, Cynoscephalæ. Thessaly was further subdivided into four districts, of which Pelasgiotis embraced the lower plain of the Peneius, and Hestiæotis and Thessaliotis respectively the northern and the southern portions of the upper plain; while the fourth, Phthiotis, which lies towards the southeast, was geographically distinct from the rest of the country, being separated from it by a watershed. The determining feature of this is the Pagasæus Sinus (Gulf of Volo), a landlocked basin, extending from Pagasæ at its head to Aphetæ at its narrow outlet, where the chain of Pelion, turning at right angles to its axis at the end of Magnesia, throws out a projecting line of broken ridges, while on the opposite side rise the heights of Othrys. In the heroic age this district was of great importance. It was the birthplace of Greek navigation, for this seems to be implied in the story of the Argonauts, who started from this neighborhood in quest of the golden fleece. From it the great Achilles came, and, according to Thucydides (i. 3), it was the early home of the Hellenic race. The site of Iolcus, the centre of so many poetic legends, is at no great distance from the modern Volo. Near that town also, at a later period, the city of Demetrias was founded by Demetrius Poliorcetes, who called it one of the three fetters of Greece, Chalcis and Corinth being the other two.

The history of Thessaly is closely connected with its geography. The fertility of the land offered a temptation to invaders, and was thus the primary cause of the early migrations. It was this motive which first induced the Thessalians to leave their home in Epirus and descend into this district, and from this movement arose the expulsion of the Bœotians from Arne, and their settlement in the country subsequently called Bœotia; while another wave of the same tide drove the Dorians also southward, whose migrations changed the face of the Peloponnese. Again, this rich soil was the natural home of a powerful aristocracy, such as the families of the Aleuadæ of Larissa and the Scopadæ of Crannon; and the absence of elevated positions was unfavorable to the foundation of numerous cities, which might have fostered the spirit of freedom and democracy. The plains, also, were suited to the breeding of horses, and consequently the force in which the Thessalian nation was strong was cavalry, a kind of troops which has usually been associated with oligarchy. The wealth and the semi-Hellenic character of the people—for in race, as in geographical position, the Thessalians held an intermediate place between the non-Hellenic Macedonians and the Greeks of pure blood—caused them to be wanting in patriotism, so that at the time of the Persian wars we find the Aleuadæ making common cause with the enemies of Greece. When they were united they were a formidable power, but, like other half-organized communities, they seldom combined for long together, and consequently they influenced but little the fortunes of the Greeks.

For several centuries during the Middle Ages Roumanian immigrants formed so large a part of the population of Thessaly that that district was called by the Byzantine writers Great Walachia (Μεγάλη Βλαχία): the Jewish traveller, Benjamin of Tudela, who passed through the country in the latter half of the 12th century, describes them as then occupying it. At the present day only a few colonies of that race remain, the principal of which are found on the western side of Olympus and in some of the gorges of Pindus. The Turkish inhabitants are settled in the larger towns, and here and there in the country districts, the most important colony being those called Koniarates, who were brought from Konieh in Asia Minor shortly before the taking of Constantinople, and planted under the southwest angle of Olympus. The Greeks, however, form the vast majority of the population, so much so that, even while the country belonged to the Ottomans, Greek was employed as the official language. In accordance with the provisions of the Berlin treaty, Thessaly was ceded to the Greeks by the Porte in 1881, and since that period it has formed a portion of the Hellenic kingdom. (H. F. T.)

THETFORD, an ancient borough and market-town, partly in Norfolk and partly in Suffolk, is situated on the Thet and Little Ouse, and on the Great Eastern Railway line between Cambridge and Norwich, 36 miles southwest of Norwich, 12 north of Bury St. Edmunds, to which there is a branch line, and 96 north-northeast of London. The Little Ouse, which divides the counties, is crossed by a cast-iron bridge erected in 1829. In the time of Edward III. the town had twenty churches and eight monasteries. There are now three churches—St. Peter's, St. Cuthbert's, and St. Mary's; of these St. Mary's, on the Suffolk side, is the largest. There are various monastic remains in the town. The most important relic of antiquity is the castle hill, a mound 1000 feet in circumference and 100 feet in height, probably the largest of the Celtic earthworks in England. The grammar school was founded in 1610. In King Street is the mansion-house occupied as a hunting lodge by Queen Elizabeth and James I. Brewing and tanning are carried on; and there are also manure and chemical works, brick and lime kilns, flour-mills, and agricultural implement works. The Little Ouse is navigable from Lynn for barges. The population of the municipal borough (area 7296 acres) in 1871 was 4166 and in 1881 it was 4032.

Thetford is supposed to have been the *Sitomagus* of the Romans. In the time of the Saxons, by whom it was called Theodford, it was the capital of East Anglia. During the heptarchy it was frequently desolated by the Danes. It was burned by them in 998 after a drawn battle between Swend and Ulfcytel, and again after Ulfcytel's second battle at Ringmere, 10th May, 1004. From the reign of Athelstan to that of King John it possessed a mint. The see of Elmham was removed to it in 1070, but it was transferred to Norwich in 1094. At Domesday it had five burgesses, but by the time of Edward III. they had increased to 953. It was incorporated by Elizabeth in 1573. It returned two members to parliament from the time of Edward VI., but was disfranchised in 1868.

THEVENOT, JEAN DE (1633–1667), an eminent Oriental traveller, was a native of Paris, where he received his education in the college of Navarre. The perusal of works of travel[1] moved him to go abroad, and his circumstances permitted him to please himself. Leaving France in 1652, he first visited England, Holland, Germany, and Italy, and at Rome he fell in with D'Herbelot, who invited him to be his companion in a projected voyage to the Levant. D'Herbelot was detained by private affairs, but Thevenot sailed from Rome in May, 1655, and, after vainly waiting five months at Malta, took passage for Constantinople alone. He remained in Constantinople till the end of the following August, and then proceeded by Smyrna and the Greek islands to Egypt, landing at Alexandria on New Year's Day, 1657. He was a year in Egypt, then visited Sinai, and, returning to Cairo, joined the Lent pilgrim caravan to Jerusalem. He visited the chief places of pilgrimage in Palestine, and, after being twice taken by corsairs, got back to Damietta by sea, and was again in Cairo in time to view the opening of the canal on the rise of the Nile (August 14, 1658). In January, 1659, he sailed from Alexandria in an English ship, taking Goletta and Tunis on the way, and, after a sharp engagement with Spanish corsairs, one of which fell a prize to the English merchantman, reached Leghorn on April 12. He now spent four years at home in studies useful to a traveller, and in November, 1663, again sailed for the East, calling at Alexandria and landing at Sidon, whence he proceeded by land to Damascus, Aleppo, and then through Mesopotamia to Mosul, Baghdad, and Mendeli. Here he entered Persia (August 27, 1664), proceeding by Kirmanshahan and Hamadan to Ispahan, where he spent five months (October, 1664,–February, 1665), and then, joining company with the merchant TAVERNIER (*q.v.*), proceeded by Shiraz and Lar to Bender-Abbas, in the hope of finding a passage to India. This was difficult, because of the opposition of the Dutch, and, though Tavernier was able to proceed, Thevenot found it prudent to return to Shiraz, and, having visited the ruins of Persepolis, made his way to Basra, and sailed for India, November 6, 1665, in the ship "Hopewell," arriving at the port of Surat, January 10, 1666. He was in India for thirteen months, and crossed the country by Golconda to Masulipatam, returning overland to Surat, from which he sailed to Bender-Abbas and went up to Shiraz.[1] He passed the summer of 1667 at Ispahan, disabled by an accidental pistol shot, and in October started for Tebriz, but died on the way at Miyana (November 28, 1667).

---

[1] His uncle Melchisedech had similar tastes, and published a well-known collection of *Voyages* (fol., Paris, 1663, *sq.*).

Thevenot was an accomplished linguist, skilled in Turkish, Arabic, and Persian, and a curious and diligent observer. He was also well skilled in the natural sciences, especially in botany, for which he made large collections in India. His personal character was admirable, and his writings are still esteemed, though it has been justly observed that unlike Chardin he saw only the outside of Eastern life. The account of his first journey was published at Paris in 1665; it forms the first part of his collected *Voyages*. The license is dated December, 1663, and the preface shows that Thevenot himself arranged it for publication before leaving on his second voyage. The second and third parts were posthumously published from his journals in 1674 and 1684 (all 4to). A collected edition appeared at Paris in 1689, and a second in 12mo at Amsterdam in 1727 (5 vols.). There is an indifferent English translation by A. Lovell (fol., London, 1687).

THIBAUT, ANTON FRIEDRICH JUSTUS (1774–1840), one of the greatest of German jurists, was born at Hameln, in Hanover, January 4, 1774, that is, ten years after his contemporary and rival Hugo, about a year before Feuerbach, and five years before Savigny. Thibaut's father was an officer in the Hanoverian army, a skilful mathematician, and, like his son, a man of much force of character. His mother was the daughter of the oberbürgermeister of the town. The Thibauts were of French descent; they came from a family which had been driven out of France on the revocation of the edict of Nantes. As a child and youth, Thibaut lived in Hameln, Harburg, and Hanover. He was fond of rowing, skating, and swimming, and, above all, of music, which remained his passion through life. As a lad he set his heart, chiefly for romantic reasons, on being a forester, and he actually spent two years as such. But he soon became disenchanted, and in 1792 went to Göttingen to study. In 1793 he moved to Königsberg, where Kant still taught. Thibaut was deeply affected by the critical philosophy; his very latest writings bear traces of it, and it is not unimportant in the history of jurisprudence in Germany that Hugo was equally influenced by it. From Königsberg Thibaut moved in 1794 to Kiel, where he formed a friendship with Niebuhr, at that time a student there. They lived for a year in the same house, taking their meals together, and holding much converse on literature and politics. Both already displayed the bent of their minds—Niebuhr despondent and affrighted at the progress of the French Revolution, Thibaut hopeful, undismayed, and certain that eventually all would be well. In 1798 he was appointed extraordinary professor of civil law, and in the same year appeared his *Versuche über einzelne Theile der Theorie des Rechts* (Kiel, 1798), a collection of essays, of which by far the most important was entitled "Ueber die Einfluss der Philosophie auf die Auslegung der Positiven Gesetze." Taking as his text an observation of Leibnitz, he sought to show that history without philosophy could not interpret and explain law. The essay was partly by anticipation a corrective of the teaching of the historical school of jurists. It enters into speculations on the possibility of forming an ideal body of law as a measure and mode of exposition of particular law,—speculations which have never been continued, certainly not by Thibaut. In 1799 he was made ordinary professor of civil law. In that year was published his *Theorie der logischen Auslegung des römischen Rechts*, one of his most remarkable works, a favorite book of Austin's, and, as his well-annotated copy in the Inner Temple library shows, one which he had most carefully studied. In 1800 Thibaut married the daughter of Professor Ehlers at Kiel. In 1802 he published a short criticism of Feuerbach's theory of criminal law. It is an excellent illustration of his good sense; it discriminates between what is good and what is unsound and crude in the writings of criminal law reformers; it recalls in many ways the speculations of Bentham. The same year appeared Thibaut's essay *Ueber Besitz und Verjährung*. In 1803 Thibaut was called to Jena, where he spent three years, made happier than they otherwise would have been by intercourse with Goethe and Schiller. At the invitation of the grand-duke of Baden he went to Heidelberg to fill the chair of civil law and to assist in organizing the university; and he never quitted that town, though he received in after years, as his fame grew, invitations to Göttingen, Munich, and Leipsic. His class was large, his influence great; and, except Hugo and Savigny, no civilian of his time was so well known. In the work of the university he took an active part; and he cultivated with rare devotion his favorite art. In 1814 appeared his *Civilistische Abhandlungen*, of which the principal was his famous essay, the parent of so much literature, on the necessity of a national code for Germany. He had no wish to enter into official or practical life. "I am Professor Thibaut, and wish to be nobody else." In 1819 he was appointed representative in the first chamber of the Baden parliament. He was also made member of the Scheidungsgericht. In 1825 appeared anonymously his work *Ueber die Reinheit der Tonkunst*, in which he eulogized the old music, and especially that of his favorite master, Palestrina. It involved him in a contest with Nägeli and other admirers of the new school of music, whose merits Thibaut was somewhat slow to own. This has been translated into English by W. H. Gladstone. In 1836 Thibaut published his *Erörterungen des römischen Rechts*. One of his last works was a contribution in 1838 to the *Archiv für die civilistische Praxis*, of which he was one of the editors (see below). He died peacefully, full of years and honor, on the 29th of March, 1840.

Thibaut was of the middle height and broad-shouldered, his eyes bright and piercing, his head noble and striking; his whole appearance told of power, simplicity, and reserve. All who knew him speak of his strong personality, his manly consistent nature. Young men loved him, and he drew to the young. If he sometimes signed his letters "*Semper idem* A. F. J. Thibaut," it was not a phrase. Every incident told of him has a curious flavor. He was much more than a jurist; he deserves to be remembered in the history of music. Palestrina and the early composers of church music were his delight. "Jurisprudence is my business; my music room is my temple." His friend, Dr. Baumstark, has left an interesting record of his musical pursuits and of the work of his "Sangverein" at Heidelberg. Among the masters of German prose Thibaut holds no mean place. Nothing could be clearer, more unpedantic and unpretentious, than his exposition; his prose is scarcely inferior to Lessing's. Like his speech, his written style was simple and manly, but it is simplicity marked by care, and is rich in the happy accidents of expression which come only to true artists. He liked the old classical models; he read and reread the classics, ancient and modern, his taste being catholic enough to include Plato and Chrysostom, Montaigne, Hume's *Essays*, Adam Smith's works, Ferguson's *Essay on the History of Civil Society*, (which he particularly admired), and the later developments of German literature.

---

[1] It was at this time that he met Chardin near Persepolis, but that somewhat envious scholar is wrong in saying that this was Thevenot's only visit to the ruins (Chardin, *Voyages*, ed. Langlès, viii. 345). See Thevenot, pt. ii. bk. 3, chap. 6.

Most of Thibaut's works have already been mentioned. Several of them, however, deserve further notice. And first as to his essay on the necessity of a code for Germany ("Ueber die Nothwendigkeit eines allgemeinen bürgerlichen Rechts für Deutschland"). No more persuasive argument for codification was ever advanced. It has all the vigor of Bentham's arguments for the same cause, but is without his pamphleteering recklessness of expression. Unlike Hugo, whose education dated back to the time when French literature was supreme in Germany and who felt himself somewhat a stranger to later German culture, Thibaut was of his own time, sensitive to the great change which had come over Germany after the battle of Leipsic, conscious of the insufficiency of Roman law, and eager to promote the greatness of his country. In his contribution to the *Archiv für die civilistische Praxis*, in 1838, on "the so-called historical and unhistorical school," he tells the history of his memorable essay on the necessity of a code for Germany. He had seen many German soldiers in 1814 about to march to Paris. He realized the change which this denoted; and out of the fulness of his heart he wrote the essay in a fortnight. The mode of treatment is more comprehensive than the theme; and to-day, perhaps partly for this reason, the essay is as readable as it ever was; jurists have not yet carried out all the suggestions which it contains. For Germany, its soil freed and its honor vindicated, a happy future had, he predicted, been opened up. "The division into small states was inevitable, and not to be deplored. The existence of great states is always in a sense unnatural; it implies a warm life only at one point,—a constant repression of individuals for a common object, and no real unity between the rulers and the subjects. In a land of small states, on the other hand, the peculiarity of each has full play; there is development of variety, and the unity of princes and people is deeper and more living." The only unity practicable and needful in Thibaut's judgment was one of law; and for such all the German Governments should labor. His review of the state of jurisprudence in Germany is severe; it recalls the contemporaneous criticism passed by Bentham on English law. Thibaut pointed out luminously the contrast between the fundamental conceptions of Roman and German society, and the inadequacy of Roman law to supply defects in German jurisprudence. It was not pleasing to many jurists to be told that a few lectures on the laws of the Persians and Chinese would do more to awaken a true judicial sense than minute disquisitions on the Roman law of intestacy—observations the full effect of which Thibaut himself did not perhaps conceive. The essay was as much a condemnation of the entire state of jurisprudence as an argument for codification: it was a challenge to civilians to justify their very existence. Savigny took up the challenge thus thrown down; and a long controversy as to points not very clearly defined took place. The glory of the controversy belonged to Savigny; the real victory rested with Thibaut. By recent legislation Germany has carried out some of the ideas of Thibaut; and others indicated but not developed in his essay remain to be completed by a scientific school of jurists. One of his works best worth reading is his *Theory of Construction*. Though directly applicable to Roman law, it is of general use. The subject is divided into two branches—"Interpretation nach der Absicht des Gesetzgeber" and "Interpretation nach dem Grunde des Gesetzes," or, as Austin expresses the distinction in a marginal note on his copy, "What the legislator would have contemplated had he conceived his purpose completely and distinctly, and what the legislator actually contemplated." It would be interesting to compare the rules of interpretation stated by Thibaut with the rules of construction, familiar to English lawyers, laid down by Coke in Heydon's Case, 3, 7*b*, *Reports*. Thibaut's best-known work is on the Pandects (*System des Pandektenrechts*, 3 vols., 1803), a part of which was translated by Lord-Justice Lindley. He was one of the earliest to criticise the divisions found in the Institutes, and he carried on with Hugo a controversy as to these points. Thibaut's own classification earlier is unsatisfactory. He divided the subject into public law (that which treats of the relations between Government and subjects), private law, and international law. Public law he subdivided into constitutional law (*Staatsrecht*, the laws binding on the sovereign) and administrative law (*Regierungsrecht*, or criminal law, and laws relating to finance and police). The laws relating to civil process were dealt with partly under administrative law and partly under private law. Status was placed partly in the former partly in the latter; and the law as to guardianship and parental authority is treated as a part of the law of police. Thibaut, however, abandoned in practice this unscientific division. One of his most interesting works is his posthumous treatise on the "Civil Code," *Lehrbuch des französischen Civilrechts in steter Vergleichun mit dem römischen Civilrecht*. While criticising the code, which he designates as in the highest degree unsystematic, he recognizes in it merits which German jurists of his time were reluctant to admit.

In modern German legal literature Thibaut's influence is not very perceptible. Even at Heidelberg it was quickly superseded by that of his successor, Vangerow, and in Germany his works are now little used as text-books. But those best able to judge Thibaut have most praised him. Austin, who owed much to him, describes him as one "who for penetrating acuteness, rectitude of judgment and depth of learning, and eloquence of exposition may be placed by the side of Von Savigny, at the head of all living civilians;" and elsewhere he praises Thibaut's indefatigable perseverance and "sagacity not surpassable." High though such eulogies are, they are scarcely adequate. In Thibaut's works are promises which he did not fulfil, and they contain fertile suggestions which future jurists may utilize. It was not the least of his merits that he introduced scientific methods into legal practice and practical sense into jurisprudence. (J. M†.)

THIELT, a town of Belgium, in the province of West Flanders, 15 miles south-southeast of Bruges, on a branch line between Ingelmunster and Deynze. It manufactures linen and woollen goods, gloves, vinegar and spirits, and has tanneries and bleacheries. There is also some trade in cattle and grain. The town was of considerable importance in the Middle Ages, but was almost entirely destroyed by fire in 1383, a calamity from which it never wholly recovered. The population in 1876 was 10,527.

THIERRY, the name of two excellent French historians, brothers (Augustin and Amédée), both of whom, though their literary and historical faculty was not quite equal, displayed the same devotion to historical study.

I. JACQUES NICOLAS AUGUSTIN THIERRY (1795–1856), the elder and most gifted, was born at Blois on the 10th May, 1795. He had no advantages of birth or fortune, but was greatly distinguished at the Blois grammar school, and entered the École Normale, an establishment which, designed on the best principles to supply France with perfectly equipped teachers, has on the whole done more service to journalism and literature than to pedagogy. He appears to have been very susceptible to personal influences, and was for a time docile to St. Simon and afterwards to Comte. But his real bent was towards more solid studies, and, under the impulse of the strong current setting at the time towards mediæval research, he began, and in 1825 published, his *History of the Norman Conquest of England*, much altered and improved in the later edition of 1840. Two years later he published important *Lettres sur l' Histoire de France*, attacking the traditional method of history-writing, and recommending recourse to the original documents. About this time the heavy calamity of blindness threatened him, and by 1830 he had totally lost his sight. His marriage, however, with Julie de Quérengal, a woman of ability, considerably lightened his misfortune, and about the same time he was elected to the Académie des Inscriptions. He continued to pursue his historical studies, now through other eyes, and in 1834 published *Dix Ans d' Études Historiques*, which was followed by his capital work, the *Récits Merovingiens*, in 1840. His later years were chiefly occupied in the study of the history of the Tiers État, which bore fruit in more than one publication. He died at Paris on May 22, 1856.

The duller school of picturesque Dryasdusts (a rather miraculous combination) who have profited by Thierry's labors and continued his work have sometimes charged both him and his brother with having entered on history with their minds full of Walter Scott, and with having subordinated facts to graphic presentation. The charge is entirely unjust, and is generally found in the mouths of those who are particularly ill qualified to make it, inasmuch as they owe Thierry nearly everything in style. By others he is described as the founder of the picturesque school, and in this capacity, no doubt, he has much to answer for. His own work, however, is of a very high and remarkable character. He had hardly any forerunners, unless Gibbon may be counted as one, and his freedom from the besetting sin of his own school—the subordination of sober history to picturesque description and romantic narrative—is best seen by comparing him with his contemporary Barante, who, however, is himself not to be named otherwise than *honoris causa*.

II. Amédée Simon Dominique Thierry (1797–1873) was the younger brother of Augustin, and was born on the 2d August, 1797. He began life as a journalist (after an essay, like his brother, at schoolmastering), was connected with the famous romantic harbinger the *Globe*, and obtained a small Government clerkship. His first book was a brief history of Guienne in 1825, and three years later appeared the *Histoire des Gaulois*, which was received with much favor, and obtained him, from the royalist premier Martignac, a history professorship at Besançon. He was, however, thought too liberal for the Government of Charles X., and his lectures were stopped, with the result of securing him, after the revolution, the important post of prefect of the Haute-Saône, which he held eight years. During this time he published nothing. In 1838 he was transferred to the council of state as master of requests, which post he held through the revolution of 1848 and the *coup d'état* till 1860, when he was made senator—a paid office, it must be remembered, and, in effect, a lucrative sinecure. He also passed through all the ranks of the Legion of Honor, became a member of the Académie des Inscriptions in 1841, and in 1862 received the honorary degree of D.C.L. at Oxford. He had, except during the time of his prefecture, never intermitted his literary work, being a constant contributor to the *Revue des Deux Mondes*, his articles (usually worked up afterwards into books) almost all dealing with Roman Gaul and its period. The chief were the *Histoire d'Attila* (1856), frequently reprinted, the *Histoire de la Gaule sous l'Administration Romaine* (1840–2), a *Tableau de l'Empire Romain*, and, in imitation of his brother, certain *Récits* of Roman history, a book of St. Jerome in 1867, and one on *Chrysostom and Eudoxia* in 1873. He died March 27, 1873.

His literary and historical genius was perhaps inferior to his brother's, and he exhibits more of the defects of the anecdotic method of writing history, but he shared Augustin's passion for going to the fountainhead and for animating the dry bones of mere chronicles and mere academic discussions with accounts of the life of peoples.

THIERS, a town of France, chef-lieu of an arrondissement in the department of Puy-de-Dôme, on the railway between Clermont and St. Étienne, 24 miles east-northeast of the former town. It is most picturesquely situated on the side of a hill, at the foot of which the Durolle rapidly descends through a narrow valley into the Dore, in its turn a tributary of the Allier. The streets, rising in steep rows, contain many wooden and gabled houses, some of which are as old as the 15th century, and a fine view of the Plain of Limagne and the Dôme Hills is obtainable from the terraces. All the processes of making cutlery may be seen at Thiers, giving employment to 12,000 workmen in the town and the villages within a radius of 6 to 7 miles. Sheath-making, tanning, and paper-making (chiefly stamps and playing cards) employ 8000 hands, and the business done reaches £1,200,000 [$5,832,000] per annum. The church of Le Moutier, so named from a Benedictine monastery of which it formed part, contains building of the 7th, 8th, and 11th centuries; the tower is more modern. There were 12,005 inhabitants in 1886 (commune 16,754).

Thiers was sacked in 523 by the soldiers of Thierry, the son of Clovis; and Gregory of Tours speaks of a wooden chapel which then existed here (on the site of the present church of Le Moutier). The church of St. Genez was built in 573 by Avitus, bishop of Clermont, on the site of the ancient *Tigernum Castrum*, was rebuilt in 1016 by Wido, lord of Thiers, and again in the 12th century. There is some curious mosaic work of the 12th century, and a fine tomb of the 13th. The commercial importance of Thiers was greatly increased three centuries ago, when the manufacture of the larger kinds of cutlery was introduced from Chateldon, between Vichy and Thiers.

THIERS, Louis Adolphe (1797–1877), "liberator of the territory," as even the short-lived gratitude of France continues to call him, was born at Marseilles on April 16, 1797. His family are somewhat grandiloquently spoken of as "cloth merchants ruined by the Revolution," but it seems that at the actual time of his birth his father was a locksmith. His mother belonged to the family of the Chéniers, and he was well educated, first at the Lycée of Marseilles, and then in the faculty of law at Aix. Here he began his lifelong friendship with Mignet, and was called to the bar at the age of 23. He had, however, little taste for law and much for literature; and he obtained (it is said by an ingenious trick, and in spite of unfair and prejudiced attempts to deprive him of it) an academic prize at Aix—for a discourse on Vauvenargues. In the early autumn of 1821 Thiers went to Paris, and was quickly introduced as a contributor to the *Constitutionnel*, at first on literary and then on general and especially political subjects, as well as art and the drama. In each of the years immediately following his arrival in Paris he collected and published a volume of his *Constitutionnel* articles, the first on the salon of 1822, the second on a tour in the Pyrenees. He was put out of all need of money by the singular benefaction of Cotta, the well-known Stuttgart publisher, who was part proprietor of the *Constitutionnel*, and made over to Thiers his dividends, or part of them. Meanwhile he became very well known in Liberal society, especially in the house of Laffitte, and he had begun and was rapidly compiling (at first with the assistance of M. Felix Bodin and afterwards alone) the celebrated *Histoire de la Révolution Française*, which founded his literary and helped his political fame. The first two volumes appeared in 1823, the last two (of ten) in 1827. The book brought him little profit at first, but became immensely popular. The well-known sentence of Carlyle, that it is "as far as possible from meriting its high reputation," is in strictness justified, not merely in regard to this, but in regard to all Thiers's historical work, which is only too frequently marked by extreme inaccuracy, by prejudice which passes the limits of accidental unfairness and sometimes seems to approach those of positive dishonesty, and by an almost complete indifference to the merits as compared with the successes of his heroes. But Carlyle himself admits that Thiers is "a brisk man in his way, and will tell you much if you know nothing." In other words the *Histoire de la Révolution* (again like its author's other work) possesses in a very high degree the gifts of clearness, liveliness, and intelligible handling which so often distinguish French writing. Coming as it did just when the reaction against the Revolution was about to turn into another reaction in its favor, it was assured of success.

For a moment it seemed as if the author had definitely chosen the lot of a literary man, even of a literary hack. He planned an *Histoire Générale*, and was about to survey mankind from China to Peru on the deck of a French man-of-war as a preliminary process. But the accession to power of the Polignac ministry in August, 1829, changed his projects, and at the beginning of the next year Thiers, with Armand Carrel, Mignet, and others, started the *National*, a new opposition newspaper, which openly attacked the older Bourbon line and was foremost in provoking the famous and fatal Ordonnances of July. Thiers himself was the soul (or at least one of the souls) of the actual revolution. What share he had in the process sometimes attributed to him of "overcoming the scruples of Louis Philippe" is no doubt a debatable question, with the problem *in limine* of the debate whether Louis Philippe had any scruples to overcome. At any rate Thiers had his reward. He ranked, if not at once, yet very soon, as one of the radical though not republican supporters of the new dynasty, in opposition to the party of which his rival Guizot was the chief literary man, and Guizot's patron the duke of Broglie the main pillar among the nobility, and which might be called by comparison Conservative. At first Theirs, though elected deputy for Aix, obtained only subordinate places in the ministry of finance. After the overthrow of his patron Laffitte, he seemed to change his politics and became much less radical, and, after the troubles of June, 1832, this tendency was strengthened or rewarded by his appointment to the ministry of the interior. He repeatedly changed his portfolio, but remained in office for four years, became president of the council and in effect prime minister, and began the series of quarrels and jealousies with Guizot which make one of the chief and not the most creditable features of the politics of the reign. At the time of his resignation in 1836 he was foreign minister, and, as usual, wished for a spirited policy in Spain, which he could not carry out. He travelled in Italy for some time, and it was not till 1838 that he began a regular campaign of parliamentary opposition, which in March, 1840, made him president of the council and foreign minister for the second time. But he held the position barely six months, and being unable to force on the king an anti-English and anti-Turkish policy, resigned on October 29, after having, as was generally thought, with the direct purpose of stirring up Anglophobia, begged the body of Napoleon from England. This was made the occasion of the ceremony immortally ridiculed by Thackeray, and, it is said, condemned by Thiers himself as unworthy of the occasion. He now had little to do with politics for some years, and spent his time on the preparation, on a much larger scale than his first work, of his *Histoire du Consulat et de l'Empire*, the first volume of which appeared in 1845, and which continued to occupy him for more than twenty years of composition and nearly twenty of publication. During the interval, though he was still a member of the chamber, he spoke rarely, but after the beginning of 1846 his appearances were more frequent, and he was evidently bidding once more for power on the liberal and reforming side. Immediately before the revolution of February he went to all but the greatest lengths, and when it broke out he and Odillon Barrot were summoned by the king, but it was too late. Thiers was unable to govern the forces he had helped to gather, and he resigned.

Under the republic he took up the position of conservative republican, which he ever afterwards maintained (his acceptance of the republic being not much more heartfelt than his subsequent acceptance, after an interval, of the empire), and he never took office. But the consistency of his conduct, especially in voting for Prince Louis Napoleon as president, was often and sharply criticised, one of the criticisms leading to a duel with a fellow deputy, Bixio. On the whole, his conduct during these years, and still more during the last years of Louis Philippe, may be said to have been not wholly creditable. He was arrested at the *coup d'état* (when some malicious and apparently false stories were spread as to his cowardice), was sent to Mazas, and then escorted out of France. But in the following summer he was allowed to return. For the next decade his history was almost a blank, his time being occupied for the most part on *The Consulate and the Empire*. It was not till 1863 that he re-entered political life, being elected by a Parisian constituency in opposition to the Government candidate. For the seven years following he was the chief speaker among the small band of anti-Imperialists in the French chamber, and was regarded generally as the most formidable enemy of the empire,—all the more formidable because he never gave occasion for taking any violent steps against him. It has been pointed out that, while nominally protesting against the foreign enterprises of the empire, he perpetually harped on French loss of prestige, and so contributed more than any one else to stir up the fatal spirit which brought on the war of 1870, and that, while constantly criticising and weakening the Government of his country, he gave it no help nor even offered any. Even when the Liberal-Imperialist Ollivier ministry was formed, he maintained at first an anything but benevolent neutrality, and then an open opposition, and it would be pleasant to feel more certain than we can feel that his vigorous denunciation of the war with Prussia was the result of honest conviction, and not merely of the fact that it was not *his* war. At any rate, it brought him great unpopularity for the moment, with a corresponding reaction of gratitude when the crash came. Again it is impossible to be sure whether mere "canniness," or something better, kept him from joining the Government of the National Defence, of which he was in a manner the author.

Nevertheless the collapse of the empire was a great opportunity for Thiers, and it was worthily accepted. He undertook in the latter part of September and the first three weeks of October a circular tour to the different courts of Europe, in the hope (which he probably knew to be a vain one, though the knowledge neither daunted his spirit nor relaxed his efforts) of obtaining some intervention, or at least some good offices. The mission was unsuccessful; but the negotiator was on its conclusion immediately charged with another—that of obtaining, if possible, an armistice directly from Prince Bismarck. For a time this also failed, as the Provisional Government would not accept the German conditions; but at last France was forced to yield. The armistice having been arranged, and the opportunity having been thus obtained of electing a National Assembly, Thiers was chosen deputy by more than twenty constituencies (of which he preferred Paris), and was at once elected by the Assembly itself practically president, nominally "chef du pouvoir exécutif." He lost no time in choosing a coalition cabinet, and then personally took up the negotiation of peace. Probably no statesman has ever had a more disgusting task; and the fact that he discharged it to the satisfaction of a vast majority, even in a nation popularly reputed the vainest, the least ballasted with common sense, and the most ungrateful to public servants who are unsuccessful, is the strongest testimony to Thiers's merits. After contesting the matter, on the one side with the determination of Germany to have the pound of flesh, on the other with the reluctance of the Assembly to submit to the knife, he succeeded in convincing the deputies that the peace was necessary, and it was (March 1, 1871) voted by more than five to one.

Thiers held office for more than two years after this event,—a length of tenure which, in the circumstances and considering the French temper, is very surprising, and shows the strength of the general conviction that he alone could be trusted. He had at first to meet and crush at once the mad enterprise of the Paris commune; and the severity which was undoubtedly shown in doing this is more than justified by two considerations,—first, that failure to suppress it would have meant anarchy throughout France; and, secondly, that the Germans would almost to a certainty have made it a pretext for further demands. Soon after this was accomplished, Thiers became (August 30) in name as well as in fact president of the republic, and he set himself with vigor and success to the tasks of rearranging the army, the finances (including the paying off of the war indemnity), and the civil service, and of procuring the withdrawal of the German army of occupation.

The strong personal will and inflexible opinions of the president had much to do with the resurrection of France; but the very same facts made it inevitable that he should excite violent opposition. It seems to be generally acknowledged that to him personally were due the establishment and retention of the republican rather than the monarchical form of government, to which latter the Assembly as first elected was notoriously disposed. He was a confirmed protectionist, and free-trade ideas had made great way in France under the empire; he was an advocate of long military service, and the devotees of *la revanche* were all for the introduction of general and compulsory but short service. Both his talents and his temper made him utterly indisposed to maintain the distant, Olympian, apparently inactive, attitude which is supposed to be incumbent on a republican president; and (for his tongue was never a carefully governed one) he sometimes let drop expressions scarcely consistent with constitutional theories of the relation of the chief of the state, whether president or king, to parliament. In January, 1872, he formally tendered his resignation; but the country was then in too manifestly disorganized a condition to allow even his enemies to accept it. His position, however, was clearly one not tenable for long in such a country as France. The Right (and not merely the Extreme Right) hated him for his opposition to the restoration of the monarchy, and with some justice reminded him of former declarations and opinions on the subject; the Extreme Left could not forgive the suppression of the commune, while some radical leaders, who may have had little sympathy with the commune itself, saw in his great reputation and imperious personality a bar to their own accession to power. His chief supporters—men like Rémusat, Barthélemy Saint-Hilaire, and Jules Simon—were men rather of the past than of the present; and he had few younger adherents.

The year 1873 was, as a parliamentary year in France, occupied to a great extent with attacks on Thiers. In the early spring regulations were proposed, and on April 13 were carried, which were intended to restrict the executive and especially the parliamentary powers of the president. On the 27th of the same month a contested election in Paris, resulting in the return of the opposition candidate, M. Barodet, was regarded as a grave disaster for the Thiers Government, and that Government was not much strengthened by a dissolution and reconstitution of the cabinet on May 19. Immediately afterwards the question was brought to a head by an interpellation moved by the duke of Broglie. The president declared that he should take this as a vote of want of confidence; and in the debates which followed a vote of this character (though on a different formal issue, and proposed by M. Ernoul) was carried by 16 votes in a house of 704. Thiers at once resigned (May 24).

He survived his fall four years, continuing to sit in the Assembly, and, after the dissolution of 1876, in the Chamber of Deputies, and sometimes, though rarely, speaking. He was also, on the occasion of this dissolution, elected senator for Belfort, which his exertions had saved for France; but he preferred the lower house, where he sat as of old for Paris. On May 16, 1877, he was one of the "363" who voted want of confidence in the Broglie ministry (thus paying his debts), and he took considerable part in organizing the subsequent electoral campaign. But he was not destined to see its success, being fatally struck with apoplexy at St. Germain-en-Laye on September 3. Thiers had long been married, and his wife and sister-in-law, Mlle. Dosne, were his constant companions; but he left no children, and had had only one—a daughter,—who long predeceased him. He had been a member of the Academy since 1834. His personal appearance was remarkable, and not imposing, for he was very short, with plain features, ungainly gestures and manners, very near-sighted, and of disagreeable voice; yet he became (after wisely giving up an attempt at the ornate style of oratory) a very effective speaker in a kind of conversational manner, and in the epigram of debate he had no superior among the statesmen of his time except Lord Beaconsfield.

Thiers is by far the most gifted and interesting of the group of literary statesmen—not statesmen who have had a *penchant* for literature, but men of letters whose literary distinction has made them politicians—which forms a unique feature in the French political history of this century. Numerous as these are, there are only two who are at all comparable to him—Guizot and Lamartine; and as a statesman he stands far above both. Nor is this eminence merely due to his great opportunity in 1870; for Guizot might under Louis Philippe have almost made himself a French Walpole, at least a French Palmerston, and Lamartine's opportunities after 1848 were, for a man of political genius, illimitable. But both failed,—Lamartine almost ludicrously,—while Thiers in hard conditions made a striking if not a brilliant success. A devil's advocate may indeed urge that his egotist and almost gasconading temperament stood him in stead in the trying circumstances of his negotiations with the powers and with Prince Bismarck,—but this is not really to his discredit. No less masterful methods than his would have sufficed to bring France into order from the chaos succeeding the fall of the empire and the invasion of the Germans. But Thiers only showed well when he was practically supreme. Even as the minister of a constitutional monarch his intolerance of interference or joint authority, his temper at once imperious and intriguing, his inveterate inclination towards *brigue*, that is to say, underhand rivalry and caballing for power and place, showed themselves unfavorably; and his constant tendency to inflame the aggressive and chauvinist spirit of his country, though it may fairly claim to have been a kind of patriotism, neglected fact, was not based on any just estimate of the relative power and interests of France, and led his country more than once to the verge—once, though he affected to warn her off, over the verge—of a great calamity. In opposition, both under Louis Philippe and under the empire, and even to some extent in the last four years of his life, his worse qualities were always manifested. But with all these drawbacks he conquered and will retain a place in what is perhaps the highest, as it is certainly the smallest, class of statesmen—the class of those to whom their country has had recourse in a great disaster, who have shown in bringing her through that disaster the utmost constancy, courage, devotion, and skill, and who have been rewarded by as much success as the occasion permitted.

As a man of letters Thiers is very much smaller. He has not only the fault of diffuseness, which is common to so many of the best-known histories of this century, but others as serious or more so. The charge of dishonesty is one never to be lightly made against men of such distinction as his, especially when their evident confidence in their own infallibility, their faculty of ingenious casuistry, and the strength of will which makes them (unconsciously, no doubt) close and keep closed the eyes of their mind to all inconvenient facts and inferences supply a more charitable explanation. But it is certain that from Thiers's dealings with the men of the first Revolution to his dealings with the battle of Waterloo, constant angry, and well-supported protests against his unfairness were not lacking. Although his search among documents was undoubtedly wide, its results are by no means always accurate, and his admirers themselves admit great inequalities of style in him. These characteristics reappear (accompanied, however, by frequent touches of the epigrammatic power above mentioned, which seems to have come to Thiers more readily as an orator or a journalist than as an historian) in his speeches, which have, since his death, been collected in many volumes by his widow. Sainte-Beuve, whose notices of Thiers are generally kindly, says of him, "M. Thiers sait tout, tranche tout, parle de tout," and this omniscience and "cocksureness" (to use the word of a prime minister of England contemporary with this prime minister of France) are perhaps the chief pervading features both of the statesman and the man of letters.

His histories, in many different editions, and his speeches, as above, are easily accessible; his minor works and newspaper articles have not, we believe, been collected in any form. Works on him, by M. Laya, M. de Mazade, his colleague and friend M. Jules Simon, and others, are numerous. But a thorough biographical study of him has not yet been made; and, though monuments enough have been raised in his own country, it is even there often complained that the incessant and futile political struggles of the last ten years have too much obscured the reputation and weakened the memory of the last great statesman of France. (G. SA.)

THIRLWALL, Connop (1797–1875), bishop of St. David's, was born at Stepney on 11th January, 1797, and was the son of the Rev. Thomas Thirlwall, at the time lecturer at St. Dunstan's, Stepney, and afterwards rector of Bowers Gifford, in Essex. The family were of Northumbrian extraction. Young Connop showed the most remarkable precocity, learning Latin at three, reading Greek at four, and writing sermons at seven. When he was twelve his admiring father published his *Primitiæ*, sermons and poems, the thoughts of an imitative boy in the style of a grown man. No especial greatness could have been safely predicted from these performances, which Thirlwall assiduously strove to suppress in after years. He shortly afterwards went to the Charterhouse, where he wrote a number of letters to a friend named John Candler, some of which have been preserved. They display the same extraordinary prematurity, but are barren of anything original except what he himself calls "sensibility to the great and beautiful in morality." By a curious coincidence his future rival in Greek history, Grote, and Hare, his coadjutor in the translation of Niebuhr, were among his schoolfellows. He took up his residence at Trinity College, Cambridge, in October, 1814, and gained the Craven university scholarship, one of three recorded instances of this honor being obtained by freshmen, and the chancellor's classical medal. In October, 1818, he was elected to a fellowship, and immediately went for a year's travel on the Continent. At Rome he gained the friendship of Bunsen, which had a most important influence on his life. On his return, "distrust of his own resolutions and convictions" led him to abandon for the time his intention of being a clergyman, and he settled down to the study of the law, "with a firm determination not to suffer it to engross my time so as to prevent me from pursuing other branches of knowledge." This was not the way to become lord chancellor, and, though he afterwards says, "My aversion to the law has not increased," he adds, "It scarcely could." How little his heart was with it was shown by the labor he soon imposed upon himself of translating and prefacing Schleiermacher's essay on the Gospel of St. Luke, "very injudiciously," says Maurice, who seems to think that it may have cost Thirlwall the archbishopric of Canterbury. The translation, nevertheless, marks an era in English theology. He further, probably influenced by Hare, who had already translated Tieck, rendered two of the latter's most recent *Novellen* into English. In 1827 he at length made up his mind to quit his uncongenial profession, and was ordained deacon the same year. Beyond all question he might have obtained the highest distinction both as jurist and advocate, had law interested him more, or other things less. No one ever possessed a more judicial mind. Of his oratory, Mill, whom he opposed at a debating society, says, "Before he had uttered ten sentences I set him down as the best speaker I had ever heard, and I have never since heard any one whom I placed above him."

It is not often that a scholar twice makes an epoch by a translation. Such was Thirlwall's destiny: he joined with Hare in translating Niebuhr's *History of Rome;* the first volume appeared in 1828. The translation was attacked in the *Quarterly* as favorable to skepticism, and the translators jointly replied. In 1831 the friends established the *Philological Museum*, which lived through only six numbers, though among Thirlwall's contributions was his masterly paper on the irony of Sophocles,—"the most exquisite criticism I ever read," says Sterling. On Hare's departure from Cambridge in 1832, Thirlwall became assistant college tutor, which led him to take a memorable share in the great controversy upon the admission of Dissenters which arose in 1834. Dr. Turton, the regius professor of divinity, had written a pamphlet objecting to the admission, on the pretext of the apprehended unsettlement of the religious opinions of young churchmen. Thirlwall replied by pointing out that no provision for theological instruction was in fact made by the colleges except compulsory attendance at chapel, and that this was mischievous. This attack upon a time-hallowed piece of college discipline brought upon him a demand for the resignation of his office as assistant tutor. He complied at once; his friends generally thought that he ought to have tested the master's power. The occurrence marked him out for promotion from a Liberal Government, and in the autumn he received the chancellor's living of Kirby-under-Dale, in Yorkshire. Though devoted to his parochial duties, he found time to begin the book which has remained the principal work of one whose performance, however great, rarely rose to the level of his power. His *History of Greece*, unfortunately for him and for us, was a commission from Lardner's *Cabinet Cyclopædia*, and was originally intended to have been condensed into two or three duodecimo volumes. The scale was enlarged, but Thirlwall always felt cramped. He seems a little below his subject, and a little below himself. Yet, such was his ability that his history is usually allowed to fall only just short of Grote's, a work undertaken with far greater enthusiasm, and executed with far greater advantages. Sterling pronounces him "a writer as great as Thucydides and Tacitus, and with far more knowledge than they." The first volume was published in 1835, the last in 1847. A noble letter from Thirlwall to Grote, and Grote's generous reply, are published in the life of the latter.

In 1840 Thirlwall was raised to the see of St. David's. The promotion was entirely the act of Lord Melbourne, an amateur in theology, who had read Thirlwall's introduction to Schleiermacher, and satisfied himself of the propriety of the appointment. "I don't intend to make a heterodox bishop if I know it," he said. Thirlwall so little expected the honor that he was absent on a pedestrian tour, and it was some days before he could be found. In most essential points he was a model bishop, and in acquainting himself with Welsh, so as to preach and conduct service in that language, he performed a feat which few bishops could have imitated. It cannot be said that he was greatly beloved by his clergy, who felt their intellectual distance too great, and were alternately frozen by his taciturnity and appalled by his sarcasm. The great monument of his episcopate is the eleven famous charges in which he from time to time reviewed the position of the English Church with reference to whatever might be the most pressing question of the day,—addresses at once judicial and statesmanlike, full of charitable wisdom and massive sense. No similar productions, it may safely be said, were ever so eagerly looked for, or carried with them such weight of authority. His endeavors to allay ecclesiastical panic, and to promote liberality of spirit, frequently required no ordinary moral courage. He was one of the four prelates who refused to inhibit Bishop Colenso from preaching in their dioceses, and the only one who withheld his signature from the addresses calling upon Colenso to resign his see. He took the liberal side in the questions of Maynooth, of the admission of Jews to parliament, of the Gorham case, and of the conscience clause. He was the only bishop who voted for the disestablishment of the Irish Church, though but as a painful necessity. Concurrent endowment would have been much more agreeable to him. For many years he was the only statesman on the bench; it would have been a great benefit to the Church of

England had it been possible to have raised him to the primacy upon the death of Archbishop Howley. But such was the complexion of ecclesiastical politics that the elevation of the most impartial prelate of his day would have been resented as a piece of party spirit.

Thirlwall's private life was happy and busy. He never married, but found sufficient outlet for his deep affectionateness of nature in his tenderness to the children of others, and to all weak things except weak-minded clergymen. He was devoted to animals, and rivalled Southey and Jeremy Bentham in his love for cats. Perhaps the most durable monument to his memory will be his incomparable volume of letters to a friend, Miss Johnes of Dolaucothy, a young lady in every way worthy to be the correspondent of such a man. Even as letters these rank with the best in the language; but as letters from age to youth, sympathizing with all its feelings, entering into all its pleasures, at once inspiring and amusing, guiding without seeming to direct, and entertaining without seeming to condescend, they are unique in their delightful branch of literature. They are also important as revealing Thirlwall's mind on numerous subjects which he has not elsewhere treated, and most interesting from their picture of simplicity of character associated with greatness of intellect, and of the multiplicity of his intellectual interests, from which novels and fine art were by no means excluded. During his latter years he took great interest in the revision of the authorized version of the Bible, and was chairman of the revisers of the Old Testament. He resigned his see in May, 1874, and retired to Bath, where he died on July 27, 1875.

As scholar, critic, and ecclesiastical statesman Thirlwall is almost above praise. He was not a great original thinker; he lacked the creative faculty and the creative impulse. The world owes such vestiges of his power as it possesses to a series of fortunate accidents —an importunate editor, vexatious church controversies, and an admirable friend. Though not most fully exerted, the force of his mind is perhaps best appreciated in the volume of his letters edited by Dean Perowne. His treatment of every question is consummate; the largest and the smallest seem alike to him. His character, with its mixture of greatness and gentleness, was thus read by Carlyle: "a right solid honest-hearted man, full of knowledge and sense, and, in spite of his positive temper, almost timid."

Thirlwall's *History of Greece* remains a standard book. His literary and theological remains have been edited by Dean Perowne in three volumes, two of which are occupied by his charges. His letters on literary and theological subjects, with a connecting memoir, have been published by Dean Perowne and the Rev. Louis Stokes. His *Letters to a Friend* were originally published by Dean Stanley, and there is a revised and corrected edition. For a general view of Thirlwall's life and character, see the *Edinburgh Review*, vol. cxliii.; for a picture of him in his diocese, *Temple Bar*, vol. lxxvi. The review of his letters in *Blackwood's Magazine* for 1852 is by the late Rev. W. Lucas Collins. (R. G.)

THIRSK, a market-town in the North Riding of Yorkshire, is situated on the North Eastern Railway, and on the Codbeck, a branch of the Swale, 21 miles south of Darlington, 11 northeast of Ripon, and 210 north of London. The Codbeck is crossed by two stone bridges connecting the old and the new town. The church of St. Mary, in the Perpendicular style, with parvise, chancel, nave, aisles, porch, and tower 80 feet in height, is the noblest church in the Riding. The chancel was repaired in 1844, and the whole building restored in 1877. The moat of the ancient castle built by the Mowbrays about 980 still remains. The principal modern buildings are the assembly rooms (1849), the mechanics' institute (1852), and the new courthouse (1886). Standing in the fertile district of the Vale of Mowbray, the town has an extensive home and foreign agricultural implement trade. Iron-founding, engineering, tanning, and brickmaking are carried on, and there are large flour-mills. The population of the parliamentary borough, now disfranchised (area 11,828 acres), in 1871 was 5734, and in 1881 it was 6312. The population of the township in 1881 was 3337.

Thirsk owes its origin to the castle of the Mowbrays, and here Roger de Mowbray erected his standard, in conjunction with the king of Scotland, against Henry II. Upon the suppression of the revolt the castle was destroyed. In the reign of Henry VII., Henry Percy, earl of Northumberland, is said to have been put to death beneath an elm tree which formerly grew on St. James's Green. Thirsk was a borough by prescription, but was never incorporated. It first returned members to parliament in the reign of Edward I., but not again till the last parliament of Edward VI. In 1832 the number of representatives was reduced to one, and in 1885 it ceased to be separately represented.

THISTLE. This term, as generally employed, is of vague application, being given to almost any herbaceous plant that is of a spiny character. More strictly, it is applied to the species of *Carduus*. These are Composite herbs with very spiny leaves, and similar bracts surrounding a head of purplish-white, tubular, 5-parted flowers seated on a pitted and hairy receptacle. The anthers have appendages both at the apex and at the base. The style has a ring of hairs at the point of bifurcation of the two stigmata. The fruit is surmounted by a tuft of silky white hairs. The species are numerous, and some are of great beauty, though not unnaturally looked on with disfavor by the farmer. The Cotton [or Scotch] Thistle, remarkable for its covering of white down, is *Onopordon Acanthium*; the Blessed Thistle[1] is *Carduus benedictus*; the Holy Thistle, the leaves of which are spotted with white, is *C. Marianus*. The common *C. lanceolatus* seems to be the most suitable prototype for the Scotch Thistle, though that honor is also conferred on *Onopordon Acanthium*, the cotton thistle, a doubtful native, and on other species. The great objection to thistles from an agricultural point of view resides in the freedom with which they produce seed, and in the vigor of their underground growth, which makes their uprooting a matter of difficulty. Partial uprooting may indeed, in the case of the perennial species, increase the mischief, for each fragment left behind may grow into a distinct plant. Annual species might be kept in check were they cut down before the flowers appear, but unless all the cultivators in a particular district co-operate the efforts of individuals are of little avail. The Globe Artichoke and Cardoon are very near allies of the thistles. The Safflower, *Carthamus*, another thistle, yields a serviceable dye; the Burdock, *Arctium lappa*, has an edible root; and numerous allied species have medicinal properties.

THISTLE, ORDER OF THE. See KNIGHTHOOD, vol. xiv. p. 125.

THISTLEWOOD CONSPIRACY, or CATO STREET CONSPIRACY, a plot formed in 1820 to murder Lord Castlereagh and other ministers of the British crown, and to seize the Bank and Mansion House and proclaim a provisional government. Its chief instigator was Arthur Thistlewood, or properly Thistlewaite, born in 1770, the son of a civil engineer in Lincolnshire, who had held a commission in the militia and afterwards in the line in the West Indies. In America and in France he had imbibed revolutionary views, and, having lost his wife's fortune in speculation and on the turf, had planned the desperate scheme probably for his own benefit as well as the good of the nation. The intention was to murder the ministers in the house of the earl of Harrowby in Mansfield Street on the evening of the 23d February. For this purpose between twenty and thirty men assembled in a stable in Cato Street, Edgeware Road, but while they were arming themselves they were pounced upon by the police, and a large number captured, though the majority, including Thistlewood, escaped. A reward of £1000 [$4860] having been offered for Thistlewood, he was arrested next day at 10 White Street. After a trial Thistlewood and four others were executed on the 1st May, while five were transported. On being asked on the scaffold if he repented, Thistlewood replied, "No, not at all; I shall soon know the last grand secret."

---

[1] [The Blessed Thistle is classified by Vaillant as *Cnicus benedictus*. The Canada thistle, *Cirsium arvense*, is common and troublesome in fields, pastures and roadsides in Canada and the northern United States.—AM. ED.]

See the *Trials of Arthur Thistlewood, James Ings, John Thomas Brunt, Richard Tidd, William Davidson, and others at the Session of the Old Bailey 17–28 April*, 1820, 2 vols., 1820, and the *Gentleman's Magazine* for the same year.

THOLUCK, FRIEDRICH AUGUST GOTTREU (1799-1877), German theologian and preacher, was born at Breslau, March 30, 1799, in humble circumstances. He received his education at the grammar school and university of his native town, and early distinguished himself by wonderful versatility of mind, a phenomenal power of acquiring languages, and an omnivorous appetite for books. A romantic love of the East and its literature led him to exchange the university of Breslau for that of Berlin, that he might study Oriental languages to greater advantage, and there he was received into the house of the Orientalist Von Dietz. He was introduced to Pietistic circles in Berlin and came specially under the influence of Baron Von Kottwitz, who became his "spiritual father," and of the historian Neander. Before deciding on the career of theological professor, he had in view that of a missionary in the East. Meanwhile he was feeling the influence to a certain degree of the romantic school, and of Schleiermacher and Hegel too, though he never sounded the depths of their systems. At length, in his twenty-first year, he finally decided to adopt the academical calling. From December, 1820, to April, 1826, he was "privat-docent" and "prof. extraordinarius" of theology in Berlin, though he was at the same time most active in the work of home and foreign missions. He lectured on the Old and New Testaments, theology, apologetics, and the history of the church in the 18th century. The first fruit of his Oriental studies and his introduction to his profession was his work *Ssufismus, sive Theosophia Persarum Pantheistica* (1821); following the same line of study he published *Blütensammlung aus der morgenländischen Mystik* (1825) and *Speculative Trinitätslehre des späteren Orients* (1826). His well-known essay on the nature and moral influence of heathenism (1822) was published by Neander, with high commendation, in his *Denkwürdigkeiten;* and his *Commentary on the Epistle to the Romans* (1824) secured him a foremost place amongst the most suggestive, if not the most accurate, Biblical interpreters of that time. Another work, which was soon translated into all the principal European languages, *Dei Lehre von der Sünde und vom Versöhner* (1823), the outcome of his own religious history, procured for him the position which he ever after held of the modern Pietistic apologist of evangelical Christianity. In 1825, with the aid of the Prussian Government, he visited the libraries of England and Holland, and on his return was appointed professor of theology at Halle, the centre of German rationalism. Here he made it his aim to combine in a higher unity the learning and to some extent the rationalism of Semler with the devout and active pietism of Francke; and, in spite of the opposition of the theological faculty of the university, he succeeded in changing the character of its theology. This he effected partly by his lectures, particularly his exegetical courses, but above all, by his personal influence upon the students, and, after 1833, by his preaching. His theological position was that of a mild and large hearted orthodoxy, which laid more stress upon Christian experience than upon rigid dogmatic belief. On the two great questions of miracles and inspiration he made great concessions to modern criticism and philosophy. The battle of his life was on behalf of personal religious experience, in opposition to the externality of rationalism, orthodoxy, or sacramentarianism. He fought this battle with weapons taken in the first instance from his own personal history, but also from the wide world of human culture, ancient and modern. Carl Schwarz happily remarks that, as the English apologists of the 18th century were themselves infected with the poison of the deists whom they endeavored to refute, so Tholuck absorbed some of the heresies of the rationalists whom he tried to overthrow. As a preacher Tholuck ranked amongst the foremost of his time. He was also one of the prominent members of the Evangelical Alliance, and few men were more widely known or more beloved throughout the Protestant churches of Europe and America than he. He died at Halle, June, 10, 1877.

After his commentaries (on Romans, the Gospel of John, the Sermon on the Mount, and the Epistle to the Hebrews) and several volumes of sermons, his best-known books are *Stunden christlicher Andacht* (1839, 8th ed, 1870), intended to take the place of Zschokke's standard rationalistic work with the same title, and his reply to Strauss's *Life of Jesus* (*Glaubwürdigkeit der evangelischen Geschichte*, 1837). He published at various times valuable contributions towards a history of rationalism,—*Vorgeschichte des Rationalismus* (1853–62), *Geschichte des Rationalismus*, i. (1865), and a number of essays connected with the history of theology and especially of apologetics. His views of inspiration were indicated in his work *Die Propheten und ihre Weissagungen* (1860), in his essay on the "Alte Inspirationslehre," *Deutsche Zeitschrift für christliche Wissenschaft* (1850), and in his *Gespräche über die vornehmsten Glaubensfragen der Zeit* (1846, 2d ed., 1867).

Siegfried, *Protestantische Kirchzeitung*, 1885, No. 45, and 1886, No. 47; Carl Schwarz, *Zur Geschichte der neuesten Theologie* (4th ed., 1869); Nippold's *Handbuch der neuesten Kirchengeschichte.*

THOMAS, ST., one of the twelve apostles. The synoptical Gospels give only his name, associating him in their lists with Matthew (Mat. x. 3; Mark iii. 18; Luke vi. 15); in Acts i. 13 he is coupled with Philip. In the Gospel of John (xi. 16; xiv. 5; xx. 24 *sq.;* xxi. 2) he appears in a characteristic light, full of personal devotion and ready to die with his Master, but slow to grasp the true significance of the redeeming death of Jesus, and incredulous of the resurrection till direct evidence convinces him of its truth and at the same time of the Divinity of his risen Lord. John translates the Aramaic name or surname Thomas (תאומא) by the Greek equivalent Didymus (twin). Tradition has it that he was the twin brother of a sister Lysia (his parents being Diophanes and Rhoa, and his birthplace Antioch; "XII. Apost. Patriæ," in *Chron. Pasch.*, ii. 142), or of a brother Elieser (*Hom. Clem.*, ii. 1), or, according to the *Acta Thomæ* (ed. Bonnet, pp. 11, 23), of Jesus Himself. The last form of the tradition seems to be derived from the name Judas Thomas, which he bears in Edessene legend (*cf.* Eusebius. *H. E.*, i. 13, 10), and implies the identification of Thomas with Judas, the brother of the Lord. The most ancient tradition makes Thomas the evangelist of Parthia (Eus., *H. E.*, iii. 1, 1); and at Edessa, which claimed to possess his bones, it was related that their missionary Thaddæus (Eus., *H. E.*, i. 13, 10), or Addai (*Doctrine of Addai*, ed. Phillips, 1876, p. 5), was sent to them by him. Later tradition, originating with the Gnostic *Acta Thomæ*, and accepted by catholic teachers from the middle of the 4th century, makes him proceed to India and there suffer martyrdom. The Indian king Gundaphorus of the *Acta* is, however, certainly identical with the historical Gondophares (see PERSIA, vol. xviii. p. 614), whose dynasty was Parthian, though his realm included regions loosely reckoned to India. The Parthian and Indian missions of Thomas may perhaps therefore be regarded as derived from a single tradition. Later authors, but not the *Acta*, give as the scene of his martyrdom the city of Calamine, which the modern Christians of St. Thomas (see below) identify with Mylapur, but which Gutschmid would connect with the Calama of Nearchus, on the coast of Gedrosia, which was under the sceptre of Gondophares. Other names of historical persons and places can be traced with more or less probability in the *Acta*, but these do not alter the utterly apocryphal character of the legend, which indeed is in many respects easier to understand if we accept the bold hypothesis of Gutschmid, that it was borrowed by the Gnostic author from a Buddhist story of the conversion of Arachosia (*N. Rhein. Mus.*, xix. 161 *sq.*).

The *Acta Thomæ*, very imperfectly published by Thilo (1823) and Tischendorf (1851), have been edited in Greek, together with the Latin *De Miraculis* and *Passio S. Thomæ*, by Bonnet (Leipsic, 1883), and in Syriac, with an English translation, by W. Wright (*Apocryphal Acts*, 2 vols, London, 1871). See also Lipsius, *Die apocryphen Apostelgeschichten*, vol. i. (Brunswick, 1883), for these and other versions of the legend. The *Acta* are said by Photius to be a part of the Περίοδοι τῶν ἀποστόλων of the Gnostic Leucius Charinus, but this unknown personage is to be thought of as a collector of Gnostic "Acts of Apostles," rather than as the first author. In spite of extensive catholic revision, they form one of the most interesting monuments of early Gnosticism. Internal evidence assigns them with great probability to the school of Bardesanes, and the very ancient allegorical hymn about the soul which is inserted in the Syriac text (p. 274 *sq.*, Eng. tr. p. 238 *sq.*) is perhaps by Bardesanes himself (*cf.* Nöldeke in *Z. D. M. G.*, 1871, p. 676). It is one of the most remarkable pieces in Syriac literature.

CHRISTIANS OF ST. THOMAS is a name often applied to the members of the ancient Christian churches of southern India, which claim him as their first founder, and honor as their second founder a certain Thomas of Jerusalem, who is said to have led a Christian colony to Malabar in 345 A.D.[1] According to their tradition, St. Thomas went from Malabar to Mylapur, now a suburb of Madras, where the shrine of his martyrdom, rebuilt by the Portuguese in 1547, still stands on Mount St. Thomas, and where a miraculous cross is shown with a Pahlavi inscription which may be as old as the end of the 7th century. We know from Cosmas Indopleustes that there were Christian churches of Persian (East-Syrian) origin, and doubtless of Nestorian creed, in Ceylon, in Malabar, and at Caliana (north of Bombay) before the middle of the 6th century, and even then St. Thomas, the reputed apostle of Persia, may have been their special saint. The ancient churches of southern India never died out or wholly lost their sense of connection with their mother church, for we find them sending deputies in 1490 to the Nestorian patriarch Simeon, who furnished them with bishops (Assemani, *Bib. Or.*, iii. 1, 590 *sq.*). Hard pressed by the Moslems, they welcomed the approach of the Portuguese, but proved by no means tractable to efforts to bring them within the Roman obedience. At length a formal union with Rome was carried through in the synod of Diamper (1599). Syriac was to remain the ecclesiastical language, but the service books were corrected and purified from error. A century and a half of foreign Jesuit rule followed, but the love of independence was not lost. A great schism took place in 1653, and of 200,000 Christians of St. Thomas only 400 remained loyal to Rome, though many of their churches were soon won back by the Carmelites. Those who remained independent fell under the influence of the Jacobite Mar Gregorius, styled patriarch of Jerusalem, who reached Malabar in 1665 as an emissary from Ignatius, patriarch of Antioch. From his time the independent Christians have been Jacobites, the counter-efforts of the Nestorians under Mar Gabriel, bishop of Adharbaijan, having apparently come to nothing after his death in 1730. Since the visit of Claudius Buchanan, whose *Christian Researches in Asia* (1811) excited great interest, much has been done for the Christians of South India by English missionary effort, and Anglicans have cultivated friendly relations with the clergy of the independent native church, while discouraging dependence on the Jacobite patriarch of Antioch.

A valuable though tedious and ill-arranged history of the Christians of St. Thomas has been written by W. Germann, *Die Kirche der Thomaschristen*, Gütersloh, 1877. See also La Croze, *Histoire du Christianisme des Indes*, The Hague, 1724; Alexius de Menezes, *Historia Ecclesiæ Malabaricæ*, Latin by F. Raulin, Rome, 1745 (especially for the synod of Diamper); Paulinus a S. Bartholomæo, *India Orientalis Christiana*, 4to, Rome, 1794.

THOMAS, ST., OF AQUINO. See AQUINAS.

THOMAS BECKET, or À BECKET. See À BECKET.

THOMAS OF CELANO, the contemporary and supposed biographer of Francis of Assisi, was born probably towards the end of the 12th century, and died about 1255. He derives his surname from CELANO (*q.v.*), in the Abruzzo Ulteriore. His name does not occur among those of the earliest disciples of Francis, but he is recorded by some historians of the order, though not by all, to have held the office of custos in various Franciscan houses (Cologne, Mainz, Worms, Spires) from 1221 onwards. An old biography of Francis, which is incorporated in the *Acta Sanctorum*, is attributed to Thomas with much probability, and nothing cogent has been urged against his authorship of the *Dies Iræ* (see HYMNS, vol. xii. p. 618), although, so far as is at present known, his name is not associated with that remarkable poem by any writer earlier than 1385.

THOMAS OF ERCELDOUNE, called also the RHYMER (*c.* 1225–*c.* 1300), occupies a prominent place as a poet and prophet in the mythical and legendary literature of Scotland. The historical person of that name figures in two charters of the 13th century, and from these it appears that he owned lands in Erceldoune (now Earlston), in Berwickshire, which were made over by his son and heir to the cloister of the Holy Trinity at Soltra, or Soutra, on the borders of the same county. He figures in the works of Barbour and Blind Harry as the sympathizing contemporary of their heroes, and Wyntoun tells how he prophesied a battle. In the folk-lore of Scotland his name is associated with numerous fragments of rhymed or alliterative verse of a more or less prophetic and oracular character; but the chief extant work with which his name is associated is the poem of *Sir Tristrem*, edited from the Auchinleck MS. by Sir Walter Scott in 1804, and again in 1886 for the Scottish Text Society by Mr. G. P. M'Neill. In the latter edition the claim of Thomas to the authorship of this work (conceded by both editors) is fully discussed.

THOMAS A. KEMPIS. See KEMPIS.

THOMASIUS, CHRISTIAN (1655–1728), German jurist and publicist, was born at Leipsic, January 1, 1655, and educated by his father Jacob Thomasius, professor of philosophy and eloquence, a learned man, and friend of Spener. Through his father's lectures Christian came under the influence of the political philosophy of Grotius and Pufendorf, and continued the study of law under Stryck at Frankfurt on the Oder. In 1681 he commenced the career of professor of law at Leipsic, and soon attracted attention by his abilities, but particularly by his daring attack upon all ancient prejudices. His views on matters of law were heretical; he made the daring innovation of lecturing in German instead of Latin; he published a monthly periodical in which he ridiculed with vast wit and humor the pedantic weaknesses of the learned; he took valiantly the side of the Pietists in their controversy with the orthodox, and defended mixed marriages of Lutherans and Calvinists. In consequence of these and other sins, he was preached against from the pulpits, forbidden to lecture or to write (May 10, 1690), and his arrest was soon commanded. He escaped the latter by flight to Berlin, and the elector Frederick III. offered him a refuge in Halle, with a salary of 500 thalers [*c.* $500] and the right to lecture there. He took part in founding the university of Halle (1694), where he became second and then first professor of law and director of the university. He was one of the most esteemed university teachers and influential writers of his day. He died, after a singularly successful and honorable career, in his 74th year, September 23, 1728.

Though not a profound and systematic philosophical thinker, but rather a clever eclectic of the common-sense school, Thomasius prepared the way for great reforms in philosophy, and, above all, in law, literature, social life, and theology. It was his mission to bring all the high matters of divine and human sciences into close and living contact with the everyday world. He made learning, law, philosophy, and theology look at everything from a rational common-sense point of view, and speak of everything in vigorous German. He thus created an epoch in German literature, philosophy, and law, and Spittler opens with him the modern period of ecclesiastical history. Tholuck pronounces him "the personified spirit of illuminism." He made it one of the aims of his life to free politics and jurisprudence from the control of theology. He fought bravely and consistently for freedom of thought and speech on religious matters. He is often spoken of in German works as the author of the "territorial system," or Erastian theory of ecclesiastical government. But he taught that the state may interfere with legal or public duties only, and not with moral or private ones. He introduced a new definition of heresy, and pronounced it a bugbear of the theologians. He would not have even atheists punished, though they should be expelled the country. He came forward as an earnest opponent of the prosecution of witches and of the use of torture. In theology he was not a naturalist or a deist, but a believer in the necessity of revealed religion for salvation. He felt strongly the influence of the Pietists at times, particularly of Spener, and there was a mystic vein in his thought; but other elements of his nature were too powerful to allow him to attach himself finally to that party.

[1] See the sketch in Syriac of the history of the church of Malabar printed and translated by Land, *Anecd. Syr.*, i. 24 *sq.* It was sent to Schaaf at Leyden in 1720 by Mar Gabriel, the last Nestorian bishop in Malabar (see Germann, p. 542).

Thomasius's most popular and influential German publications were his periodical *Monatsgespräche, vornehmlich über neue Bücher* (1688); *Einleitung zur Vernunftlehre* (1691, 5th ed. 1719); *Vernünftige Gedanken über allerhand auserleserne, gemischte, philosophische, und juristische Händel* (1723-26); *Geschichte der Weisheit und Thorheit* (3 vols., 1693); *Kurze Lehrsätze von dem Laster der Zauberei mit dem Hexenprocess* (1704); *Weitere Erläuterungen der neueren Wissenschaft Anderer Gedanken kennen zu lernen* (1711).

See Heinrich Luden's *Christian Thomasius nach seinen Schicksalen und Schriften*, 1805; Zeller's *Geschichte der Philosophie in Deutschland*, 2d ed., 1875, pp. 162-171; Gass, *Geschichte der Protestantischen Dogmatik*, ii. 484 *sq.*: the histories of German literature, especially Hettner's *Geschichte der deutschen Lit. im 18ten Jahrh.*; Tholuck's article in Herzog's *Real-Encyklop.*

THOMPSON, SIR BENJAMIN, COUNT RUMFORD (1753–1814), an eminent man of science, enlightened philanthropist, and sagacious public administrator, was born at Woburn, in Massachusetts, in 1753, and died at Auteuil, near Paris, in 1814. His family had been settled in New England since the middle of the century preceding his birth, and belonged to the class of moderately wealthy farmers. His father died while Thompson was very young, and his mother speedily married a second time. But he seems to have been well cared for, and his education was so far from neglected that according to his own statement, he was at the age of fourteen sufficiently advanced "in algebra, geometry, astronomy, and even the higher mathematics," to calculate a solar eclipse within four seconds of accuracy. In 1766 he was apprenticed to a storekeeper at Salem, in New England, and while in that employment occupied himself in chemical and mechanical experiments, as well as in engraving, in which he attained to some proficiency. The outbreak of the American war put a stop to the trade of his master, and he thereupon left Salem and went to Boston, where he engaged himself as assistant in another store. He afterwards applied himself to the study, with a view to the practice, of medicine, and then (although, as he affirms, for only six weeks and three days) he became a school teacher—it is believed at Bradford on the Merrimack. Thompson was at that period between eighteen and nineteen years old, and at nineteen, he says, "I married, or rather I was married." His wife was the widow of a Colonel Rolfe, and the daughter of a Mr. Walker, "a highly respectable minister, and one of the first settlers at Rumford," now called Concord, in New Hampshire. His wife was possessed of considerable property, and was his senior by fourteen years. This marriage was the foundation of Thompson's success. Within three years of it, however, he left his wife in America to make his way to wealth and distinction in Europe, and, although his only child by her, a daughter, subsequently joined him, he never saw and, so far as anything appears to the contrary, never attempted or desired to see her again.

Soon after his marriage Thompson became acquainted with Governor Wentworth of New Hampshire, who, struck by his appearance and bearing, conferred on him the majority of a local regiment of militia. He speedily became the object of distrust among the friends of the American cause, and it was considered prudent that he should seek an early opportunity of leaving the country. On the evacuation of Boston by the royal troops, therefore, in 1776, he was selected by Governor Wentworth to carry despatches to England. On his arrival in London he almost immediately attracted the attention of Lord George Germaine, secretary of state, who appointed him to a clerkship in his office. Within a few months he was advanced to the post of secretary of the province of Georgia, and in about four years he was made under-secretary of state. His official duties, however, did not materially interfere with the prosecution of scientific pursuits, and in 1779 he was elected a fellow of the Royal Society. Among the subjects to which he especially directed his attention were the explosive force of gunpowder, the construction of firearms, and the system of signalling at sea. In connection with the last, he made a cruise in the Channel fleet, on board the "Victory," as a volunteer under the command of Admiral Sir Charles Hardy. On the resignation of Lord North's administration, of which Lord George Germaine was one of the least lucky and most unpopular members, Thompson left the civil service, and was nominated to a cavalry command in the revolted provinces of America.[1] But the War of Independence was practically at an end, and in 1783 he finally quitted active service, with the rank and half-pay of a lieutenant-colonel. He now formed the design of joining the Austrian army, for the purpose of campaigning against the Turks, and so crossed over from Dover to Calais with Gibbon, who, writing to his friend Lord Sheffield, calls his fellow-passenger "Mr. Secretary-Colonel-Admiral-Philosopher Thompson." At Strasburg he was introduced to Prince Maximilian, afterwards elector of Bavaria, and was by him invited to enter the civil and military service of that state. Having obtained the leave of the British Government to accept the prince's offer, he received the honor of knighthood from George III., and during eleven years he remained at Munich as minister of war, minister of police, and grand chamberlain to the elector. His political and courtly employments, however, did not absorb all his time, and he contributed during his stay in Bavaria a number of papers to the *Philosophical Transactions*. But that he was sufficiently alert as the principal adviser of the elector the results of his labors in that capacity amply prove. He reorganized the Bavarian army; he suppressed mendicity and found employment for the poor; and he immensely improved the condition of the industrial classes throughout the country by providing them with work and instructing them in the practice of domestic economy. Of the prompt and the business-like manner in which he was wont to carry his plans into execution a single example may serve as an illustration. The multitude of beggars in Bavaria had long been a public nuisance and danger. In one day Thompson caused no fewer than 2600 of these outcasts and depredators in Munich and its suburbs alone to be arrested by military patrols, and transferred by them to an industrial establishment which he had prepared for their reception. In this institution they were both housed and fed, and they not only supported themselves by their labors but earned a surplus for the benefit of the electoral revenues. The principle on which their treatment proceeded is stated by Thompson in the following memorable words: "To make vicious and abandoned people happy," he says, "it has generally been supposed necessary first to make them virtuous. But why not reverse this order? Why not make them first happy, and then virtuous?" In 1791 he was created a count of the Holy Roman Empire, and chose his title of Rumford from the name as it then was of the American township to which his wife's family belonged. In 1795 he visited England, one incident of his journey being the loss of all his private papers, including the materials for an autobiography, which were contained in a box stolen from off his post-chaise in St. Paul's Churchyard. During his residence in London he applied himself to the discovery of methods for curing smoky chimneys and the contrivance of improvements in the construction of fireplaces. But he was quickly recalled to Bavaria, Munich being threatened at once by an Austrian and a French army. The elector fled from his capital, and it was entirely owing to Rumford's energy and tact that a hostile occupation of the city was prevented. It was now proposed that he should be accredited as Bavarian ambassador in London; but the circumstance that he was a British subject presented an insurmountable obstacle. He, however, again came to England, and remained there in a private station for several years. In 1799 he, in conjunction with Sir Joseph Banks, projected the establishment of the Royal Institution, which received its charter of incorporation from George III. in 1800. Rumford himself selected Sir Humphry Davy as the first scientific lecturer there. Until 1804, when he definitively settled in France, Rumford lived at the Royal Institution in Albemarle Steet, or at a house which he rented at Brompton, where he passed his time in the steady pursuit of those researches relating to heat and light and the economy of fuel on which his scientific fame is principally based. He then established himself in Paris, and married (his first wife having been dead for many years) as his second wife the wealthy widow of Lavoisier, the celebrated chemist. With this lady he led an extremely uncomfortable life, till at last they agreed to separate. Rumford took up his residence at Auteuil, where he died suddenly in 1814 in the sixty-second year of his age.

---

[1] [In 1781 he went to New York and raised a loyal regiment called "The King's American Dragoons." After a brief service as lieutenant-colonel at the north, he joined the invading forces at the south and fought in the campaign against General Marion in South Carolina. In a despatch to General Leslie, dated Feb. 25, 1782, Col. Thompson wrote, "We had the good fortune this morning to fall in with a chosen corps under the command of General Marion in person, which we attacked and totally routed, killing a considerable number of them, taking sixteen prisoners, and driving General Marion and the greater part of his army into the Santee, where it is probable a great many of them perished."—AM. ED.]

He was the founder and the first recipient of the Rumford medal of the London Royal Society. He was also the founder of the Rumford medal of the American Academy of Arts and Sciences and of the Rumford professorship in Harvard university. His complete works were published by the American Academy of Arts and Sciences at Boston in 1871; and a full and extremely interesting memoir of the author (by George E. Ellis) which was issued with them was republished in London by Messrs. Macmillan in 1876. (F. DR.)

THOMPSON, Thomas Peronnet (1783–1869), mathematician and political writer, was born at Hull in 1783. He was educated at the Hull grammar school, and in October, 1798, entered Queen's College, Cambridge. He entered the navy as midshipman in the "Isis" in 1803, but in 1806 exchanged to the army. Through his acquaintance with Wilberforce, he was appointed governor of Sierra Leone in 1808, but was recalled on account of his hostility to the slave trade. In 1812 he returned to his military duties, and, after serving in the south of France, was in 1815 attached as Arabic interpreter to an expedition against the Wahhabees of the Persian Gulf, with whom he negotiated a treaty (dated January, 1820) in which the slave trade was for the first time declared piracy. He was promoted major in 1825, lieutenant-colonel in 1829, and major-general in 1854. He entered parliament as member for Hull in 1835, and afterwards sat for Bradford. He took a prominent part in the corn-law agitation, his *Catechism of the Corn Laws* (1827) being by far the most effective pamphlet published on the subject. He was joint-editor of the *Westminster Review*, to which he contributed a large number of articles republished in 1824 in six volumes, under the title *Exercises, Political and Others*. His mathematical publications were of a somewhat eccentric kind. He published a *Theory of Parallels* (1844), and was also the author *of Geometry without Axioms*, in which he endeavored to "get rid" of axioms and postulates. His new *Theory of Just Intonation* (1850) is, however, a contribution of great value to the science of musical acoustics, and has gone through many editions. It may be said to form the basis of the tonic sol-fa system of music. He died 6th October, 1869.

THOMSON, Sir Charles Wyville (1830–1882), was born at Bonsyde, Linlithgowshire, became professor of natural history in Aberdeen, Cork, Belfast, and finally Edinburgh, and will be specially remembered as a student of the biological conditions of the depths of the sea. Being interested in crinoids, and stimulated by the results of the dredgings of Sars in the deep sea off the Norwegian coasts, which had conclusively disposed of the error of Edward Forbes, that animal life ceased at a depth of a few hundred fathoms, he succeeded, along with Dr. W. B. Carpenter, in obtaining the loan of H.M.S. "Lightning" and "Porcupine," for successive deep-sea dredging expeditions in the summers of 1868 and 1869. It was thus shown that animal life existed in abundance down to depths of 650 fathoms, that all invertebrate groups were represented (largely by Tertiary forms hitherto believed to be extinct), and, moreover, that deep-sea temperatures are by no means so constant as was supposed, but vary considerably, and indicate an oceanic circulation. Further dredging expeditions at greater and greater depths followed. The remarkable results gained for hydrography as well as zoology, in association with the practical needs of ocean telegraphy, soon led to the granting of H.M.S. "Challenger" for a circumnavigating expedition, and Thomson sailed at the end of 1872 as director of the scientific staff, the cruise lasting three years and a half. On his return he received many academic honors, and was knighted. In 1877 he published two volumes of a preliminary account of the results of the voyage, meanwhile carrying on his administrative labors in connection with the disposition of the special collections and publication of the monographs of these. His health, never robust, was meanwhile giving way; from 1879 he ceased to perform the duties of his chair, and he died in 1882.

See obituary notice in *Proc. Roy. Soc. Edin.*, 1883, also Thomson's *Voyage of H.M.S. Challenger*, London, 1877, and Thomson and Murray, *Reports of the Voyage of H.M.S. Challenger*, Edinburgh, 1885.

THOMSON, James (1700–1748), author of *The Seasons*, was a native of the Scottish Border country, his father being successively minister of the parishes of Ednam and Southdean, in Roxburghshire. He was born at Ednam on September 11, 1700, and was reared at a distance from the social influences and literary fashions that helped to form and fix the manner of the "classical" school, the monotony of which he was the first to break. Amidst the bare breezy hills and glens of a Border parish, his youth was safe against the ascendency of the taste established in the metropolis. Jedburgh school and Edinburgh university gave him his book learning of the ordinary type; and he was fortunate enough to have neighbors of extraordinary accomplishment, who opened his eyes to the poetic side of nature, and encouraged him in verse-making. The teacher from whom he learnt most was a Mr. Riccalton, or Riccaulton, a graduate of Edinburgh, who had taken to farming, but was afterwards persuaded to enter the church, and made some contributions to theological literature. This scholarly enthusiast taught Latin to the boys of Jedburgh in an aisle of the church, and encouraged Thomson in his poetical turn by example as well as precept. We have the poet's own acknowledgment that the first hint of the *Seasons* came from a striking dramatic poem by Riccaulton entitled *A Winter's Day*. As a schoolboy Thomson wrote verses, and at the university he continued the practice, but his early efforts were not particularly promising. He was intended for the ministry, and was for five years a student of divinity; but in 1725 he determined to follow his friend and classfellow David Mallet to London, and seek his fortune there. Through the influence of Lady Grizel Baillie, herself a song-writer, he obtained a tutorship in the family of Lord Binning; but the plain-looking and plain-mannered poet had not the adroitness of his friend Mallet, and he gave up the post after a few months. It was while he lingered in the neighborhood of Barnet, without employment, without money, with few friends, saddened by the loss of his mother (his father had died when he was eighteen), that Thomson conceived the idea of the first of his poems on the Seasons, *Winter*. The lines—

> Welcome, kindred glooms,
> Congenial horrors, hail!

came from the heart; they expressed his own forlorn mood on the approach of the winter of 1725. *Winter* appeared in the spring of 1726. A publisher, Millan, —not Millar, who afterwards published for him,—gave him three guineas for the poem. The tradition is that it attracted no notice for a month, but that, at the end of that time, a literary clergyman, Whatley, chanced to take it up from a bookseller's counter, and at once rushed off to the coffee-houses to proclaim the discovery of a new poet. The town received the discovery with acclamation, in another month a second edition was called for. No time could have been better suited for the appreciation of Thomson's striking qualities; they were so entirely unlike what the public had for many years been accustomed to. The fresh treatment of a simple theme, the warm poetical coloring of commonplace incidents, the freedom and irregularity of the plan, the boldness of the descriptions, the manly and sincere sentiment, the rough vigor of the verse, took by surprise a generation accustomed to witty satire and burlesque, refined diction, translations from the classics, themes valued in proportion to their remoteness from vulgar life. Thomson at once became famous, and, his naturally easy temper roused to full exertion, vigorously followed up his success with *Summer* and an *Ode to the Memory of Sir Isaac Newton*. *Spring* was completed and published in 1728. A longer interval elapsed before the appearance of *Autumn*; it was published in 1730, and followed presently by a handsome edition of the whole four *Seasons*. Meantime, drawn into the ardent political strife of the time, he had produced, in 1729, his *Britannia*, and early in 1730 had made his first attempt as a dramatist with *Sophonisba*. From this time there was a manifest slackening either in his will or in his power to produce. He was appointed travelling tutor to the son of Sir Charles Talbot, travelled with his pupil on the Continent, and in 1733 obtained a small sinecure in the Court of Chancery. It may have been this removal of the spur of necessity that made him take longer over his poems. But it is a fair theory that the rigid taste of the time for finish, which he had unconsciously defied with triumphant results, began to make good an ascendency over him, and that he wrote less because he was cramped by fear of the critics. None of the other *Seasons* have the same large and careless freedom as *Winter*; *Autumn* especially, the last of them, is much more labored, and his revisions and enlargements in successive editions show an anxious ambition after the finish of the classical school. However this may be, he hesitated long over his next poem, *Liberty*; the first part was published in 1734 and the conclusion in 1736. He intended it to be his masterpiece, but with all his care and pains it has fallen into deserved oblivion. In 1737 he lost his sinecure by the death of his patron, but was recompensed by a pension from the prince. Poverty, rather than natural fitness or inclination, drove him again to dramatic composition. *Agamemnon* was produced in 1738, with indifferent success. Next year a play, written in the interest of the prince and the opposition, was interdicted by the lord chamberlain. The masque of *Alfred*, written by Thomson in conjunction with Mallet, and containing the song *Rule Britannia*, was produced in 1740, *Tancred and Sigismunda* in 1745. A year before this last event the "poetical posture" of the poet's income was improved by his appointment to the sinecure office of surveyor-general of the Leeward Islands. The *Castle of Indolence* was his last work. It was not published till the year of his death (1748), but he had been long engaged upon it. The poem is full of character and humor, with here and there passages of elaborately rich description; it is fuller than any other of the personality of the poet, of the good nature, generosity, and solid wisdom which gained him the affection of so many friends; but still it is in the *Seasons*, and especially in the first of them, that Thomson is seen at his best and strongest.

Till the advent of Scott and Byron, Thomson was the most widely popular poet in our language; and as late as the middle of this century a sumptuous edition, illustrated by the Etching Club, was printed three times within ten years (1842–1852). The popular verdict on Thomson has been unanimously justified by critics. (W. M.)

THOMSON, James (1834–1882), author of *The City of Dreadful Night*, was born at Port Glasgow, in Renfrewshire, on November 23, 1834, the eldest child of a mate in the merchant shipping service. His mother was a deeply religious woman of the Irvingite sect, and it is not improbable that it was from her the son inherited his sombre and imaginative temperament. On her death, James, then in his seventh year, was procured admission into the Caledonian Orphan Asylum, from which he went out into the world as an assistant army schoolmaster. At the garrison at Ballincollig, near Cork, he encountered the one brief happiness of his life: he fell passionately in love with, and was in turn as ardently loved by, the daughter of the armorer-sergeant of a regiment in the garrison, a girl of very exceptional beauty and cultivated mind. Two years later, when Thomson was at the training college at Chelsea, he suddenly received news of her fatal illness and death. The blow prostrated him in mind and body; and the former endured a hurt from which it never really recovered. Henceforth his life was one of gloom, disappointment, misery, and poverty, rarely alleviated by episodes of somewhat brighter fortune. While in Ireland he had made the acquaintance of Mr. Charles Bradlaugh, then a soldier stationed at Ballincollig, and it was under his auspices (as editor of the *London Investigator*) that Thomson first appealed to the public as an author, though actually his earliest publication was in *Tait's Edinburgh Magazine* for July, 1858, under the signature "Crepusculus." In 1860 was established the paper with which Mr. Bradlaugh has been so long identified, *The National Reformer*, and it was here, among other productions by James Thomson, that appeared (1863) the powerful and sonorous verses "To our Ladies of Death," and (1874) his chief work, the sombre and imaginative *City of Dreadful Night*. In October, 1862, Thomson left the army, and through Mr. Bradlaugh (with whom for some subsequent years he lived) gained employment as a solicitor's clerk. In 1869 he enjoyed what has been described as his "only reputable appearance in respectable literary society," in the acceptance of his long poem, "Sunday up the River," for *Fraser's Magazine*, on the advice, it is said, of Charles Kingsley. In 1872 Thomson went to the Western States of America, as the agent of the shareholders in what he ascertained to be a fraudulent silver mine; and the following year he received a commission from *The New York World* to go to Spain as its special correspondent with the Carlists. During the two months of his stay in that distracted country he saw little real fighting, and was himself prostrated by a sunstroke. On his return to England he continued to write in *The Secularist* and *The National Reformer*, under the at last well-known initials "B. V."[1] In 1875 he severed his connection with *The National Reformer*, owing to a disagreement with its editor; henceforth his chief source of income (1875–1881) was from the monthly periodical known as *Cope's Tobacco Plant*. Chiefly through the exertions of his friend and admirer, Mr. Bertram Dobell, Thomson's best known book, *The City of Dreadful Night, and other Poems*, was published in April, 1880, and at once attracted wide attention; it was succeeded in the autumn by *Vane's Story, and other Poems*, and in the following year by *Essays and Phantasies*. All his best work was produced between 1855 and 1875 ("The Doom of a City," 1857; "Our Ladies of Death," 1861; *Weddah and Om-el-Bonain;* "The Naked Goddess," 1866–7; *The City of Dreadful Night*, 1870–74). In his latter years too Thomson often sought refuge from his misery of mind and body in the Lethe of opium and alcohol. His mortal illness came upon him in the house of a poet friend; and he was conveyed to University College hospital, in Gower Street, where shortly after he died (June 3, 1882). He was buried at Highgate cemetery, in the same grave, in unconsecrated ground, as his friend Austin Holyoake.

To the productions of James Thomson already mentioned may be added the posthumous volume entitled *A Voice from the Nile, and other Poems* (1884), which has the advantage of Mr. Bertram Dobell's valuable prefatory memoir and an etched portrait of the poet. This volume contains much that is interesting, but nothing to increase Thomson's reputation. If an attempt be made to point to the most apparent literary relationship of the author of *The City of Dreadful Night*, one might venture the suggestion that James Thomson was a younger brother of De Quincey. If he has distinct affinity to any writer it is to the author of *Suspiria de Profundis;* if we look further afield, we might perhaps discern shadowy prototypes in Leopardi, Heine, and Baudelaire. But, after all, Thomson holds so unique a place as a poet that the effort at classification may well be dispensed with. If he maintains his own lonely little height, it will be as a distinct individuality. His, it is absolutely certain, was no literary pessimism, no assumed gloom. The poem "Insomnia" is a distinct chapter of biography; and in "Mater Tenebrarum" and elsewhere among his writings self-revelative passages are frequent. The merits of Thomson's poetry are its imaginative power, its sombre intensity, its sonorous music; to these characteristics may be added, in his lighter pieces, a Heine-like admixture of strange gayety, pathos, and caustic irony. Much the same may be said of his best prose. His faults are a monotony of epithet, the not infrequent use of mere rhetoric and verbiage, and perhaps a prevailing lack of the sense of form; to these may be added an occasional vulgar recklessness of expression, as in parts of *Vane's Story* and in some of his prose writings. Time will reduce his noteworthy work within a narrow compass, but within that limit it will be found as remarkable as it is unique.

THOMSON, JOHN (1778–1840), amateur landscape painter—Thomson of Duddingston, as he is commonly styled.—was born on September 1, 1778, at Dailly, Ayrshire. His father, grandfather, and, as we are informed, great-grandfather also, were clergymen of the Church of Scotland. The father determined that his son should follow the ancestral profession, and, greatly against his natural bent,—for all his thoughts turned instinctively towards art,—he acceded to the parental wish. He studied in the university of Edinburgh; and, residing with his elder brother, Thomas Thomson, afterwards celebrated as an antiquarian and feudal lawyer, he made the acquaintance of Francis Jeffrey, and other young members of the Scottish bar afterwards notable. The pursuit of art, however, was not abandoned; during the recess he sketched in the country, and, while attending his final college session, he studied for a month under Alexander Nasmyth. After his father's death he became, in 1800, his successor as minister of Dailly; and in 1805 he was translated to the parish of Duddingston, close to Edinburgh. The practice of art was now actively resumed, and it came to be continued throughout life—apparently without any very great detriment to pastoral duties. Thomson's popularity as a painter increased with his increasing artistic skill; and, having mastered his initial scruples against receiving artistic fees, on being offered £15 [$72.90] for a landscape—reassured by "Grecian" Williams's stout assertion that the work was "worth thrice the amount"—the minister of Duddingston began to dispose of the productions of his brush in the usual manner. In 1830 he was made an honorary member of the Royal Scottish Academy. Besides that of art, Thomson had other singularly varied tastes and aptitudes. He was an accomplished performer on violin and flute, an exact and well-read student of physical science, and one of the writers on optics in the early numbers of the *Edinburgh Review*. His life passed peacefully away in the kindly and charitable discharge of his clerical duties, varied by the enthusiastic pursuit of his art, and the enjoyment of intercourse with a singularly wide and eminent circle of friends, which among artists, included Turner and Wilkie, and among men of letters Wilson and Scott,—the latter of whom desired that Thomson, instead of Turner, should have illustrated the collected edition of his works. He died at Duddingston on the 27th of October, 1840 (not the 20th, as stated by some authorities). Thomson was twice married, and his second wife, the widow of Mr. Dalrymple of Cleland, was herself also a skilful amateur artist.

Thomson holds an honorable position as the first powerful landscapist that Scotland produced, and he is still among her greatest. His style was founded, in the first instance, upon the practice of the Dutch masters; but ultimately he submitted to the influence of the Poussins and the Italians, rightly believing that their method—in the richer solemnity of its color and the deeper gravity of its chiaroscuro—was more truly fitted for the portrayal of the scenery of Scotland, more in harmony with the gloom and the glory of its mountains and its glens and the passion of its wave-vexed cliffs. But to the study of the art of the past he joined a close and constant reference to nature which kept his own work fresh and original, though, of course, he never even approached such scientific accuracy in the rendering of natural form and effect as is expected from even the tyro in our recent schools of landscape. His art is clearly distinguished by "style"; at their best, his works show skilful selection in the leading lines of their composition and admirable qualities of abstract color and tone. Thomson is fairly represented in the Scottish National Gallery; and the Aberlady Bay of that collection, with the soft infinity of its clouded gray sky, and its sea which leaps and falls again in waves of sparkling and of shadowed silver, is fit to rank among the triumphs of Scottish art.

THOR. See ÆSIR, vol. i. p. 189, and MYTHOLOGY, vol. xvii. p. 162.

THOREAU, HENRY DAVID (1817–1862), one of the most strongly-marked individualities of modern times, spent the greater part of his life in the neighborhood of the place where he was born [12th July]—Concord, a village town of Massachusetts, pleasantly situated some twenty miles northwest of Boston, amidst a pastoral country of placid beauty. To Thoreau this Concord country contained all of beauty and even grandeur that was necessary to the worshipper of nature: he once journeyed to Canada; he went west on one occasion; he sailed and explored a few rivers; for the rest, he haunted Concord and its neighborhood as faithfully as the stork does its ancestral nest. John Thoreau, his father, who married the daughter of a New England clergyman, was the son of a John Thoreau of the isle of Jersey, who, in Boston, married a Scottish lady of the name of Burns. This last-named John was the son of Philippe Thoreau and his wife Marie le Gallais, persons of pure French blood, settled at St. Helier, in Jersey. From his New England Puritan mother, from his Scottish grandmother, from his Jersey-American grandfather, and from his remoter French ancestry Thoreau inherited distinctive traits: the Saxon element perhaps predominated, but the "hauntings of Celtism" were prevalent and potent. The stock of the Thoreaus was a robust one; and in Concord the family, though never wealthy nor officially influential, was ever held in peculiar respect. As a boy, Henry drove his mother's cow to the pastures, and thus early became enamoured of certain aspects of nature and of certain delights of solitude. At school and at Harvard university he in nowise distinguished himself, though he was an intelligently receptive student; he became, however, proficient enough in Greek, Latin, and the more general acquirements to enable him to act for a time as a master. But long before this he had become apprenticed to the learning of nature in preference to that of man: when only twelve years of age he had made collections for Agassiz, who had then just arrived in America, and already the meadows and the hedges and the stream-sides had become cabinets of rare knowledge to him. On the desertion of schoolmastering as a profession Thoreau became a lecturer and author, though it was the labor of his hands which mainly supported him through many years of his life: professionally he was a surveyor. In the effort to reduce the practice of economy to a fine art he arrived at the conviction that the less labor a man did, over and above the positive demands of necessity, the better for him and for the community at large; he would have had the order of the week reversed,—six days of rest for one of labor. It was in 1845 he made the now famous experiment of Walden. Desirous of proving to himself and others that man could be as independent of his kind as the nest-building bird, Thoreau retired to a hut of his own construction on the pine-slope over against the shores of Walden Pond,—a hut which he built, furnished, and kept in order entirely by the labor of his own hands. During the two years of his residence in Walden woods he lived by the exercise of a little surveying, a little jobwork, and the tillage of a few acres of ground which produced him his beans and potatoes. His absolute independency was as little gained as if he had camped out in Hyde Park; relatively he lived the life of a recluse. He read considerably, wrote abundantly, thought actively if not widely, and came to know beasts, birds, and fishes with an intimacy more extraordinary than was the case with St. Francis of Assisi. Birds came at his call, and forgot their hereditary fear of man; beasts lipped and caressed him; the very fish in lake and stream would glide, unfearful, between his hands. This exquisite familiarity with bird and beast would make us love the memory of Thoreau, if his egotism were triply as arrogant, if his often meaningless paradoxes were even more absurd, if his sympathies were even less humanitarian than we know them to have been. His *Walden*, the record of this fascinating two years' experience, must always remain a production of great interest and considerable psychological value. Some years before Thoreau took to Walden woods he made the chief friendship of his life, that with Emerson. He became one of the famous circle of the transcendentalists, always keenly preserving his own individuality amongst such more or less potent natures as Emerson, Hawthorne, and Margaret Fuller. From Emerson he gained more than from any man, alive or dead; and, though the older philosopher both enjoyed and learned from the association with the younger, it cannot be said that the gain was equal. There was nothing electrical in Thoreau's intercourse with his fellow-men; he gave off no spiritual sparks. He absorbed intensely, but when called upon to illuminate in turn was found wanting. It is with a sense of relief that we read of his having really been stirred into active enthusiasm anent the wrongs done the ill-fated John Brown. With children he was affectionate and gentle, with old people and strangers considerate. In a word, he loved his kind as animals, but did not seem to find them as interesting as those furred and feathered. In 1847, Thoreau left Walden Lake abruptly, and for a time occupied himself with lead-pencil making, the parental trade. He never married, thus further fulfilling his policy of what one of his essayist-biographers has termed "indulgence in fine renouncements." At the comparatively early age of forty-five he died, on 6th May, 1862. His grave is in the beautiful cemetery of Sleepy Hollow, beside those of Hawthorne and Emerson.

---

[1] Bysshe Vanolis: "Bysshe," as the commonly used Christian name of Shelley Thomson's favorite writer; and "Vanolis," an anagram of Novalis, the pseudonym of F. von HARDENBERG (*q.v.*).

Thoreau's fame will rest on *Walden*, the *Excursions*, and his *Letters*, though he wrote nothing which is not deserving of notice. Up till his thirtieth year he dabbled in verse, but he had little ear for metrical music, and he lacked the spiritual impulsiveness of the true poet. He had occasional flashes of insight and could record beautifully, notwithstanding: his little poem "Haze" is surcharged with concentrated loveliness. His weakness as a philosopher is his tendency to base the laws of the universe on the experience-born, thought-produced convictions of one man—himself. His weakness as a writer is the too frequent striving after antithesis and paradox. If he had had all his own originality without the itch of appearing original, he would have made his fascination irresistible. As it is, Thoreau holds a unique place. He was a naturalist, but absolutely devoid of the pedantry of science; a keen observer, but no retailer of disjointed facts. He thus holds sway over two domains: he has the adherence of the lovers of fact and of the children of fancy. He must always be read, whether lovingly or interestedly, for he has all the variable charm, the strange saturninity, the contradictions, austerities, and delightful surprises, of Nature herself.

See W. E. Channing, *Thoreau the Poet Naturalist*, Boston, 1873; F. B. Sanborn, *Biography of Thoreau* (American Men of Letters Series); H. A. Page,[1] *Biography of Thoreau;* Emerson, Introduction to *Excursions;* J. Russell Lowell, *My Study Windows;* Will. H. Dircks, Introduction to *Walden;* Professor Nichol, *American Literature*, pp. 312 *sq.;* Mr. Burroughs; Mr. Henry James, etc. After Thoreau's death were published (besides the *Excursions*, 1863) *The Maine Woods* (1864); *Cape Cod* (1865); *Letters and Poems* (1865); *A Yankee in Canada* (1866). In the *Atlantic Monthly*, in 1862, appeared "Walking," "Autumn Tints," and "Wild Apples;" in 1863 "Night and Moonlight." His best known work, *Walden*, constitutes the second volume of the series called *The Camelot Classics;* otherwise Thoreau's productions are not widely known in Britain.

THORIUM, in chemistry, is the name of the as yet unisolated radical of *thoria*, one of the now numerous "rare earths." Thoria was discovered by Berzelius in 1828 in the mineral now called thorite. It is present also in pyrochlor, monazite, orangite, and euxenite. Being similar to the oxides TiO_2 and ZrO_2 of titanium and zirconium, thoria is assumed to be a binoxide ThO_2. The atomic weight, according to Cleve, is $Th = 233$, O being 16.

THORN (Polish, *Toruñ*), an interesting old town in the province of West Prussia, is situated on the right bank of the Vistula, near the point where the river enters Prussian territory, 26 miles southeast of Bromberg and 92 miles south of Dantzic. Its position near the frontier of Russian Poland makes it a strategic point of importance; and, strongly fortified since 1818, in 1878 it was converted into a fortress of the first class. The "old town," founded in 1231, and the "new town," founded thirty-three years later, were united in 1454, and both retain a number of quaint buildings dating from the 15th and 16th centuries, when Thorn was a flourishing member of the Hanseatic League. The town-house, of the 14th and 16th centuries, the churches of St. John and the Virgin, with aisles as lofty as the nave, the ruined castle of the Teutonic order, and the gates, leaning tower, and fragments of the walls, all of the 13th century, are among the most interesting edifices. The ancient wooden bridge, now burned down, at one time the only permanent bridge across the lower Vistula, has been succeeded by a massive iron railway viaduct, half a mile long. Thorn carries on an active trade in grain, timber, wine, colonial wares, and iron, and has manufactures of leather, hats, starch, candles, and numerous other articles. It is famous for its "Pfefferkuchen," a kind of gingerbread. Part of the trade is carried on by vessels on the Vistula. In 1885 the population was 23,914 (in 1816, 7909), about three-fifths being Protestants and two-fifths (chiefly Poles) Roman Catholics.

---

[1] [H. A. Page was the pseudonym of Alexander Hay Japp, a Scottish writer.—Am. Ed.]

Thorn, founded in 1231 by the Teutonic order as an outpost against the Poles, was colonized mainly from Westphalia. The first peace of Thorn, between the order and the Poles, was concluded in 1411. In 1454 the townspeople revolted from the knights of the order, destroyed their castle, and attached themselves to the king of Poland. This resulted in a war, which was terminated in 1466 by the second peace of Thorn. In the 15th and 16th centuries Thorn was a Hanse town of importance, and received the titles of "queen of the Vistula" and "the beautiful." It embraced the Reformation in 1557, and in 1645 it was the scene of a "colloquium charitativum," or discussion betwixt the doctors of the rival creeds, which, however, resulted in no agreement. In 1724 a riot between the Protestant and Roman Catholic inhabitants was seized upon by the Polish king as a pretext for beheading the burgomaster and nine other leading Protestant citizens, an act of oppression which is known as the "bloodbath of Thorn." The second partition of Poland conferred Thorn upon Prussia; by the treaty of Tilsit it was assigned to the duchy of Warsaw; but since the congress of Vienna it has again been Prussian. Copernicus was born at Thorn in 1473.

THORNBACK is the name given to a species of ray (*Raja clavata*) which is found all round the coasts of Europe, and locally abundant; it derives its name from the peculiar armature of the skin of its body, the upper and lower surfaces of the body of the female being armed with scattered, more or less numerous, large round osseous bucklers, each with a spine in the centre; the tail also is armed with rows of similar bucklers. In the male fish these bucklers are absent, or nearly so. The thornback does not grow to the same large size as the skates, a specimen three feet across being considered large. It is more valued as food than the other rays, and consumed in large quantities, fresh as well as salted.

THORNHILL, Sir James (1676–1734), historical painter, was born at Melcombe Regis, Dorset, in 1676, coming of an ancient but impoverished county family. His father died while he was young, but he was befriended by his maternal uncle, the celebrated Dr. Sydenham, and apprenticed to Thomas Highmore, sergeant-painter to King William III., a connexion of the Thornhill family. Little is known regarding his early career. About 1715 he visited Holland, Flanders, and France; and, having obtained the patronage of Queen Anne, he was in 1719–20 appointed her sergeant-painter in succession to Highmore, and was ordered to decorate the interior of the dome of St. Paul's with a series of eight designs, in chiaroscuro heightened with gold, illustrative of the life of that apostle,—a commission for which Louis Laguerre had previously been selected by the commissioners for the repair of the cathedral. He also designed and decorated the saloon and hall of Moor Park, Herts, and painted the great hall at Blenheim, the princesses' apartments at Hampton Court, the hall and staircase of the Southsea Company, the chapel at Wimpole, the staircase at Easton-Neston, Northamptonshire, and the hall at Greenwich Hospital, usually considered his most important and successful work, upon which he was engaged from 1708 to 1727. Among his easel pictures are the altar-pieces of All Soul's and Queen's College chapels, Oxford, and that in Melcombe Regis church; and he executed such portrait subjects as that of Sir Isaac Newton, in Trinity College, Cambridge, and the picture of the House of Commons in 1730, now in the possession of the earl of Hardwicke, in which he was assisted by Hogarth, who married Jane, his only daughter. He also produced a few etchings in a slight and sketchy but effective manner, and executed careful full-sized copies of Raphael's cartoons, which now belong to the Royal Academy. About 1724 he drew up a proposal for the establishment of a royal academy of the arts, and his scheme had the support of the lord-treasurer Halifax, but Government declined to furnish the needful funds. Thornhill then opened a drawing-school in his own house in James Street, Covent Garden, where instruction continued to be given till the time of his death. He acquired a considerable fortune by his art, and was enabled to repurchase his family estate of Thornhill, Dorsetshire. In 1715 he was knighted by George I., and in 1719 he represented Melcombe Regis in parliament, a borough for which Sir Christopher Wren had previously been member. Having been removed from his office by some court intrigue, and suffering from broken health and repeated attacks of gout, he retired to his country seat, where he died on the 4th of May, 1734. His son James was also an artist. He succeeded his father as sergeant-painter to George II., and was appointed "painter to the navy."

The high contemporary estimate of Sir James Thornhill's works has not since been confirmed; in spite of Dr. Young, "late times" do *not*

> "Understand
> How Raphael's pencil lives in Thornhill's hands."

He is weak in drawing,—indeed, when dealing with complicated figures he was assisted by Thomas Gibson; and, ignorant of the great monumental art of Italy, he formed himself upon the lower model of Le Brun. It must, however, be admitted that, in the departments of art which he chose for his own, he was the best native painter of his time.

THORWALDSEN, Bertel (1770–1844), a very able Danish sculptor, was the son of an Icelander who had settled in Copenhagen, and there carried on the trade of a wood-carver. While very young, Bertel Thorwaldsen learnt to assist his father; at the age of eleven he entered the Copenhagen school of art, and soon began to show his exceptional talents. In 1792 he won the highest prize, the travelling studentship, and in 1796 he started for Italy in a Danish man-of-war. On the 8th of March, 1797, he arrived in Rome, where Canova was at the height of his popularity. Thorwaldsen's first success was the model for a statue of Jason, which was highly praised by Canova, and he received the commission to execute it in marble from Thomas Hope, a wealthy English art-patron. From that time Thorwaldsen's success was assured; and he did not leave Italy for twenty-three years. In 1819 he returned to Denmark, where he was received with the greatest enthusiasm. He was there commissioned to make the colossal series of statues of Christ and the twelve apostles which are now in the Fruenkirche in Copenhagen. These were executed after his return to Rome, and were not completed till 1838, when Thorwaldsen again returned to Denmark. He died suddenly in the Copenhagen theatre in 1844, and bequeathed a great part of his fortune for the building and endowment of a museum in Copenhagen, and also left to fill it all his collection of works of art, and the models for all his sculpture,—a very large collection, exhibited to the greatest possible advantage. Thorwaldsen is buried in the courtyard of this museum, under a bed of roses, by his own special wish.

On the whole Thorwaldsen was the most successful of all the imitators of classical sculpture, and many of his statues of pagan deities are modelled with much of the antique feeling for breadth and purity of design. His attempts at Christian sculpture, such as the tomb of Pius VII. in St. Peter's and the Christ and Apostles at Copenhagen, are less successful, and were not in accordance with the sculptor's real sympathies, which were purely classic. Thorwaldsen's private life was not admirable: he worked sometimes with feverish eagerness; at other times he was idle for many months together. A great number of his best works exist in private collections in England. His not very successful statue of Lord Byron, after being refused a place in Westminster Abbey, was finally deposited in the library of Trinity College, Cambridge. The most widely popular among Thorwaldsen's works have been some of his bas-reliefs, such as the Night and the Morning, which he is said to have modelled in one day. In the main his popularity is now a thing of the past, owing chiefly to the reaction against the pseudo-classic style of sculpture.

A well illustrated account of Thorwaldsen and his works is given by Eugène Plon, *Thorwaldsen, sa Vie*, etc., Paris, 1880; see also Andersen, *B. Thorwaldsen*, Berlin, 1845; Killerup, *Thorwaldsen's Arbeiten*, etc., Copenhagen, 1852; and Thiele, *Thorwaldsen's Leben*, Leipsic, 1852–1856.

THOU, Jacques Auguste de (1553–1617), sometimes known by the Latinized form Thuanus, as his great history is by the name *Thuana*, was born at Paris on October 8, 1553. He belonged to a family of distinction in the Orléanais, of which the elder branch had, he tells us, been *noblesse d'épée*, though he gives no particulars except of those who had for some generations been *noblesse de robe*. He and his were closely connected by birth, marriage, and friendship with several of those great legal families—the Harlays, the Huraults, the Brularts, the Lamoignons, and others—which for many generations furnished France with by far her most valuable class of public men. The historian's father was Christophe de Thou, first president of the parlement of Paris, a man whose strong legal and religious prejudices against the Huguenots have rather obscured, in the eyes of historians, his undoubted ability and probity. Christophe's brothers, Adrien and Nicolas, were both men of mark, the former being also a lawyer, and the latter ultimately becoming bishop of Chartres, in which capacity he "instructed" Henry IV. at his conversion. De Thou's mother was Jacqueline Tuleu, dame de Céli. He was a delicate child, and seems by his own account to have been rather neglected by his parents; perhaps it was for this reason that, though he grew stronger with age, he was destined for the church. He took minor orders, and obtained some benefices. It was, however, to the legal side of the ecclesiastical profession that he was devoted, and, after being at school at the Collége de Bourgogne, he studied law at Orleans, Bourges, and Valence, being at the last two places under the tuition of jurists no less celebrated than Hotman and Cujas. It was not, however, till he approached middle life that he definitely renounced the clerical profession, married, and accepted lay offices. Meanwhile, he had travelled much and discharged important duties. In 1573, that he might profit by seeing foreign parts, he was attached to the suite of Paul de Foix, who was sent on a circular mission of compliment to the Italian princes, and with him De Thou visited Turin, Milan, Mantua, Venice, Rome, Florence, and many minor places. On his return he studied for four years, travelling to the Netherlands in the interval, and in 1579 to Germany. Two years later he was appointed to a royal commission in Guienne, and made the acquaintance of Henry of Navarre and of Montaigne. He had already become the friend of most of the eminent men of letters of the time, from Ronsard downwards, and was particularly intimate with Pierre Pithou, the soul of the future *Satire Menippée*. De Thou, by all his sympathies, belonged to that later and better phase of the *politique* party which devoted itself to the maintenance of royalty as the one hope of France; and, when Henry III. was driven from his capital by the violence of the Guises and the League, De Thou followed him to Blois. After his renunciation of orders, he had been made, first, master of requests, and then president *à mortier*, which was the highest dignity he ever attained. After the death of Henry III. he attached himself closely to his successor, and in 1593 was appointed (he was a great bibliophile) *grand maître* of the royal library, in succession to Amyot, the translator of Plutarch and Longus. It was in this same year that he began his history, the composition of which was interrupted, not only by his regular official duties, but by frequent diplomatic missions at home and abroad. His most important employment of all was on the commission which, in face of the greatest difficulties on both sides, successfully carried through the negotiations for the edict of Nantes. Nor were his duties as a diplomatist intermitted by the death of Henry IV., though the Government of Marie de' Medici refused him the place of *premier president* which he desired, and hurt his feelings by appointing him instead a member of the financial commission which succeeded Sully. This appointment he rather strangely chose to think a degradation. It is, however, absurd to say that the affair, which he survived six years, had anything to do with his death. That, as far as it was hastened by any mental affliction, seems to have been rather due to grief at the death of his second wife, Gasparde de La Châtre, of whom and of his sons and daughters by her (his first marriage with Marie de Barbançon had been childless) he was extremely fond. His eldest son, François Auguste, was the friend of Cinq Mars, and shared his downfall and fate. But this was a quarter of a century after De Thou's own death, which happened on May 7, 1617.

Although a distinguished ornament of France, De Thou has nothing to do, properly speaking, with French literature. Besides minor works in Latin (a poem on hawking, some paraphrases of the Bible, etc.), he wrote also in Latin the great history which has made his name known. Entitled *Historiæ Sui Temporis*, it begins shortly before the author's birth (in 1546), and extends to 1607, ten years before his death. The first part, in eighteen books, was published in 1604; the second, third, and fourth appeared in 1606 and the two following years. The last part, which makes a total of 138 books, did not appear till 1620, under the care of the author's friends Rigault and Dupuy, whom he had named his literary executors. The first named likewise put final touches to De Thou's autobiography, which, also written in Latin, appears in French in most collections of French memoirs. It contains minute details of the author's life down to 1607, mixed with rather miscellaneous descriptions of interesting places which he had visited (such as Mont St. Michel, an eagle's eyrie in Dauphiné, etc.); and its composition is said to have been partly determined by the obloquy cast by bigoted adherents of the papacy on the *History*. De Thou was indeed obnoxious to these on many grounds. He had helped to negotiate the edict of Nantes; he had opposed the acknowledgment in France of the decrees of Trent; he had been a steady Anti-Leaguer; and he was accused of speaking in the *History* itself of Protestants and Protestantism, not merely with criminal mildness, but with something like sympathy. It is needless to say that these blots in the *History* have seemed beauties to later and more dispassionate students. There is no doubt that the charges of partiality on minor and mostly personal points are either disprovable or unimportant; and the whole seems to be as fair and as carefully accurate as at such a time was possible. On the other hand, the work is undoubtedly planned and executed on much too large a scale, and the inclusion of events in foreign countries, on which the author was often but ill-informed, has not improved it. But it is clearly and on the whole excellently written, and will always be, as far as any general contemporary history can be so called, the great authority for at least the French part of its subject and period. It was first published as a whole when, as above-mentioned, the last part appeared in 1620, and it was several times reprinted. More than a hundred years later, in 1733, an Englishman, Samuel Buckley, working in part on the materials of Thomas Carte, produced at London what is recognized as the standard edition of the original, in 7 vols. folio. The standard French translation was made immediately afterwards by a group of literary men, the best known of whom were the Abbé Desfontaines and Prévost, the author of *Manon Lescaut*. A choice copy of the first edition of the first part, with the arms of Henry IV. on the binding, is in the British Museum library.

THOUSAND AND ONE NIGHTS. The *Thousand and One Nights*, commonly known in English as

The Arabian Nights' Entertainments, is a collection of tales written in Arabic, which first became generally known in Europe in the early part of last century through the French translation by Antoine GALLAND (*q.v.*), and rapidly attained such universal popularity that it is unnecessary to describe the contents of the book. But the origin of the *Arabian Nights* claims discussion in this place. In the *Journal Asiatique* for 1827, p. 253, Von Hammer drew attention to a passage in the *Golden Meadows* of Masʿúdí (ed. Barbier de Meynard, iv. 89 *sq.*), written in 943 A.D., in which certain stories current among the old Arabs are compared with "the books which have reached us in translations from Persian, Indian, and Greek, such as the book of *Hezár Afsáne*, a title which, translated from Persian into Arabic, means 'the thousand tales.' This book is popularly called *The Thousand and One Nights*, and contains the story of the king and his vizier and of his daughter Shírazád and her slave girl Dínázád. Other books of the same kind are the book of *Ferza and Símás*, containing stories of Indian kings and viziers, the book of Sindibád, etc." Von Hammer concluded that the *Thousand and One Nights* were of Persian or Indian origin. Against this conclusion De Sacy protested in a memoir (*Mém. de l'Acad. des Inscr.*, 1833, x. 30 *sq.*), demonstrating that the character of the book we know is genuinely Arabian, and that it must have been written in Egypt at a comparatively recent date. Von Hammer in reply adduced, in *Jour. As.*, 1839, ii. p. 175 *sq.*, a passage in the *Fihrist* (987 A.D.), which is to the following effect:

> "The ancient Persians were the first to invent tales, and make books of them, and some of their tales were put in the mouths of animals. The Ashghanians, or third dynasty of Persian kings, and after them the Sásánians, had a special part in the development of this literature, which found Arabic translators, and was taken up by accomplished Arabic literati, who edited it and imitated it. The earliest book of the kind was the *Hezár afsán* or *Thousand Tales*, which had the following origin. A certain Persian king was accustomed to kill his wives on the morning after the consummation of the marriage. But once he married a clever princess called Shahrazád, who spent the marriage night in telling a story which in the morning reached a point so interesting that the king spared her, and asked next night for the sequel. This went on for a thousand nights, till Shahrazád had a son, and ventured to tell the king of her device. He admired her intelligence, loved her, and spared her life. In all this the princess was assisted by the king's stewardess Dínázád. This book is said to have been written for the princess Ḥomái (MSS. Ḥomání), daughter of Bahman. . . . It contains nearly two hundred stories, one story often occupying several nights. I have repeatedly seen the complete book, but it is really a meagre and uninteresting production" (*Fihrist*, ed. Flügel, p. 304).

Persian tradition (in Firdausí) makes Princess Ḥomái the daughter and wife of Bahman Ardashír, *i.e.*, Artaxerxes I. Longimanus. She is depicted as a great builder, a kind of Persian Semiramis, and is a half-mythical personage already mentioned in the Avesta, but her legend seems to be founded on the history of Atossa and of Parysatis. Firdausí says that she was also called Shahrazád (Mohl, v. 11). This name and that of Dínázád both occur in what Masʿúdí tells of her. According to him, Shahrazád was Ḥomái's mother (ii. 129), a Jewess (ii. 123). Bahman had married a Jewess (i. 118), who was instrumental in delivering her nation from captivity. In ii. 122 this Jewish maiden who did her people this service is called Dínázád, but "the accounts," says our author, "vary." Plainly she is the Esther of Jewish story. Ṭabarí (i. 688) calls Esther the mother of Bahman, and, like Firdausí, gives to Ḥomái the name of Shahrazád. The story of Esther and that of the original *Nights* have in fact one main feature in common. In the former the king is offended with his wife, and divorces her; in the *Arabian Nights* he finds her unfaithful, and kills her. But both stories agree that thereafter a new wife was brought to him every night, and on the morrow passed into the second house of the women (Esther), or was slain (*Nights*). At length Esther or Shahrazád wins his heart and becomes queen. The issue in the Jewish story is that Esther saves her people; in the *Nights* the gainers are "the daughters of the Moslems," but the old story had, of course, some other word than "Moslems." Esther's foster-father becomes vizier, and Shahrazád's father is also vizier. Shahrazád's plan is helped forward in the *Nights* by Dínázád, who is, according to Masʿúdí, her slave girl, or, according to other MSS., her nurse, and, according to the *Fihrist*, the king's stewardess. The last account comes nearest to Esther ii. 15, where Esther gains the favor of the king's chamberlain, keeper of the women. It is also to be noted that Ahasuerus is read to at night when he cannot sleep (Esther vi. 1). And it is just possible that it is worth notice that, though the name of Ahasuerus corresponds to Xerxes, Josephus identifies him with Artaxerxes I.

Now it may be taken as admitted that the book of Esther was written in Persia, or by one who had lived in Persia, and not earlier than the 3d century B.C. If now there is real weight in the points of contact between this story and the *Arabian Nights*—and the points of difference cannot be held to outweigh the resemblances between two legends, each of which is necessarily so far removed from the hypothetical common source—the inference is important for both stories. On the one hand, it appears that (at least in part) the book of Esther draws on a Persian source; on the other hand, it becomes probable that the *Nights* are older than the Sásánian period, to which Lane, iii. 677, refers them.

It is a piece of good fortune that Masʿúdí and the *Fihrist* give us the information cited above. For in general the Moslems, though very fond of stories, are ashamed to recognize them as objects of literary curiosity. In fact, the next mention of the *Nights* is found only after a lapse of three centuries. Maḳrízí, describing the capital of Egypt, quotes from a work of Ibn Saʿíd (*c.* 1250 A.D.), who again cites an older author (Al-Ḳorṭobí), who, in speaking of a love affair at the court of the caliph Al-Ámir (1097–1130), says "what is told about it resembles the romance of Al-Baṭṭál, or the *Thousand and One Nights*" (*Ḥiṭaṭ*, Búláḳ ed., i. 485, ii. 181).

That the *Nights* which we have are not the original translation of the *Hezár Afsáne* is certain, for the greater part of the stories are of Arabian origin, and the whole is so thoroughly Mohammedan that even the princes of remote ages who are introduced speak and act as Moslems. It might be conceived that this is due to a gradual process of modernization by successive generations of story-tellers. But against this notion, which has been entertained by some scholars, Lane has remarked with justice that, much as MSS. of the *Nights* differ from one another in points of language and style, in the order of the tales, and the division into nights, they are all so much at one in essentials that they must be regarded as derived from a single original. There is no trace of a recension of the text that can be looked on as standing nearer to the *Hezár Afsáne*. And the whole local color of the work, in point of dialect and also as regards the manners and customs described, clearly belongs to Egypt as it was from the 14th to the 16th century. Some points, as De Sacy and Lane have shown, forbid us to place the book earlier than the second half of the 15th century. Galland's MS. copy, again, was in existence in 1548. Lane accordingly dates the work from the close of the 15th century or the beginning of the 16th, but this date appears to be too late. For Abu'l-Maḥásin, an Egyptian historian who died in 1470, writing of Ḥamdi, a famous highwayman of Baghdad in the 10th century, remarks that he is probably the figure who used to be popularly spoken of as Ahmed al-Danaf (ed. Juynboll, ii. 305). Now in the *Nights* Ahmed al-Danaf really plays a part corresponding to that of the historical Ḥamdi, being now a robber (Lane, ii. 404) and again a captain of the guard (Lane ii. 249). It would seem that Abu'l-Maḥásin had read or heard the stories in the *Nights*, and was thus led to compare the historical with the fictitious character. And, if this be so, the *Nights* must have been composed very soon after 1450.[1]

No doubt the *Nights* have borrowed much from the *Hezár Afsáne*, and it is not improbable that even in the original Arabic translation of that work some of the Persian stories were replaced by Arab ones. But that our *Nights* differ very much from the *Hezár Afsáne* is further manifest from the circumstance that, even of those stories in the *Nights* which are not Arabian in origin, some are borrowed from books mentioned by Mas‘údí as distinct from the *Hezár Afsáne.* Thus the story of the king and his son and the damsel and the seven viziers (Lane, chap. xxi. note 51) is in fact a version of the *Book of Sindbád*,[2] while the story of Jalí‘ád and his son and the vizier Shammás (M'Naghten, iv. 366 *sq.; cf.* Lane, iii. 530) corresponds to the book of *Ferza and Símás.*[3]

Not a few of the tales are unmistakably of Indian or Persian origin, and in these poetical passages are rarely inserted. In other stories the scene lies in Persia or India, and the source is foreign, but the treatment thoroughly Arabian and Mohammedan. Sometimes, indeed, traces of Indian origin are perceptible, even in stories in which Hárún al-Rashíd figures and the scene is Baghdad or Baṣra.[4] But most of the tales, in substance and form alike, are Arabian, and so many of them have the capital of the caliphs as the scene of action that it may be guessed that the author used as one of his sources a book of tales taken from the era of Baghdad's prosperity.

The late date of the *Nights* appears from sundry anachronisms. In the story of the men transformed into fish—white, blue, yellow, or red according as they were Moslems, Christians, Jews, or Magians (Lane, i. 99),—the first three colors are those of the turbans which, in 1301, Mohammed b. Keláún of Egypt commanded his Moslem, Christian, and Jewish subjects respectively to wear.[5] Again, in the story of the humpback, whose scene is laid in the 9th century, the talkative barber says, "this is the year 653" (= 1255 A.D.; Lane, i. 332, writes 263, but see his note), and mentions the caliph Mostanṣir (died 1242), who is incorrectly called son of Mostaḍí.[6] In the same story several places in Cairo are mentioned which did not exist till long after the 9th century (see Lane, i. 379)[7] The very rare edition of the first 200 nights published at Calcutta in 1814 speaks of cannon, which are first mentioned in Egypt in 1383; and all editions sometimes speak of coffee, which was discovered towards the end of the 14th century, but not generally used till 200 years later. In this and other points, *e.g.*, in the mention of a mosque founded in 1501 (Lane, iii. 608), we detect the hand of later interpolators, but the extent of such interpolations can hardly perhaps be determined even by a collation of all copies. For the nature and causes of the variations between different copies the reader may consult Lane, iii. 678, who explains how transpositions actually arise by transcribers trying to make up a complete set of the tales from several imperfect copies.

Many of the tales in the *Nights* have an historical basis, as Lane has shown in his notes. Other cases in point might be added: thus the chronicle of Ibn al-Jauzí (died 1200 A.D.) contains a narrative of Kamar, slave girl of Shaghb, the mother of Al-Moktadir, which is the source of the tale in Lane, i. 310 *sq.*, and of another to be found in M'Naghten, iv. 557 *sq.;* the latter is the better story, but departs so far from the original that the author must have had no more than a general recollection of the narrative he drew on.[8] There are other cases in the *Nights* of two tales which are only variations of a single theme, or even in certain parts agree almost word for word. Some tales are mere compounds of different stories put together without any art, but these perhaps are, as Lane conjectures, later additions to the book; yet the collector himself was no great literary artist. We must picture him as a professional story-teller equipped with a mass of miscellaneous reading, a fluent power of narration, and a ready faculty for quoting, or at a push improvising, verses. His stories became popular, and were written down as he told them,—hardly written by himself, else we should not have so many variations in the text, and such insertions of "the narrator says," "my noble sirs," and the like. The frequent coarseness of tone is proper to the condition of Egyptian society under the Mameluke sultans, and would not have been tolerated in Baghdad in the age to which so many of the tales refer. Yet with all their faults the *Nights* have beauties enough to deserve their popularity, and to us their merit is enhanced by the pleasure we feel in being transported into so entirely novel a state of society.

The original of some of the most interesting tales in Galland's version, as "Aladdin and the Wonderful Lamp," "Ali Baba and the Forty Thieves," has just been discovered by Dr. Zotenberg in a MS. recently acquired by the National Library at Paris. A careful examination of this MS. and of the Wortley-Montagu MS. in the Bodleian may lead perhaps to a more certain conclusion as to the time of composition.

The *Thousand and One Nights* became known in Europe through A. Galland's French version (12 vols., 12mo, Paris, 1704–12); the publication was an event in literary history, the influence of which can be traced far and wide. This translation, however, left much to be desired in point of accuracy, and especially failed to reproduce the color of the original with the exactness which those who do not read merely for amusement must desire. It was with a special view to the remedying of these defects that Lane produced in 1840 his admirably accurate, if somewhat stilted, translation, enriched with most valuable notes and a discussion of the origin of the work (new edition, with some additional notes, 3 vols., 8vo., London, 1859). Lane's translation omits the tales which he deemed uninteresting or unfit for a European public. No full translation into English can be published, and, though two such have been privately printed, and one of these (by Sir R. Burton) is being reproduced in an expurgated form, Lane's version is still unsuperseded for all serious use. Of the Arabic text of the *Nights* the principal editions are (1) M'Naghten's edition, 4 vols., 8vo, Calcutta, 1839–42; (2) the Breslau edition, 12 vols., 12mo, 1835–43, the first 8 vols. by Habicht, the rest by Fleischer (compare as to the defects of Habicht's work, Fleischer, *De Glossis Habichtianis*, Leipsic, 1836); (3) the first Búlák edition, 4 vols., 1862–3. (M. J. DE G.)

THRACE is a name which was applied at various periods to areas of different extent, but for the purposes of this article it will be taken in its most restricted sense, as signifying the Roman province which was so called (Thracia, see Plate of the Roman empire in vol. xx.) after the district that intervened between the river Ister (Danube) and the Hæmus Mountains (Balkan) had been formed into the separate province of Mœsia, and the region between the rivers Strymon and Nestus, which included Philippi, had been added to Macedonia. The boundaries of this were—towards the N. the

---

[1] The hypothesis of gradual and complete modernization is also opposed to the fact that the other romances used by Cairene story-tellers (such as those of ‘Antar and of Saïf) retain their original local color through all variations of language and style.

[2] On this famous book, the Syriac *Sindibán*, the Greek *Syntipas*, and the *Seven Sages* of the European West, see SYRIAC LITERATURE (vol. xxii. p. 894) and SPAIN (vol. xxii. p. 368).

[3] De Sacy and Lane suppose that the original title of the Arabic translation of the *Hezár Afsáne* was *The Thousand Nights*. But most MSS. of Mas‘údí already have *The Thousand and One Nights*, which is also the name given by Makrízí. Both ciphers perhaps mean only "a very great number," and Fleischer (*De Glossis Habichtianis*, p. 4) has shown that 1001 is certainly used in this sense.

Hæmus, on the E. the Euxine Sea, on the S. the Propontis, the Hellespont, and the Ægean, and towards the W. the Nestus. The most distinguishing features of the country were the chain of Rhodope (Despoto-dagh) and the river Hebrus (Maritza). The former separates at its northernmost point from the Hæmus, at right angles, and runs southward at first, nearly parallel to the Nestus, until it approaches the sea, when it takes an easterly direction; this bend is referred to by Virgil in the line (*Georg.*, iii. 351)—

> Quaque *redit* medium Rhodope porrecta sub axem.

The summits of this chain are higher than those of Hæmus, and not a few of them range from 5000 to 8000 feet; the highest point, so far as is at present known (for these mountains have been imperfectly explored), rises towards the northwest, near the point where now stands the famous Bulgarian monastery of Rilo. The Hebrus, together with its tributaries which flow into it from the north, east, and west, drains nearly the whole of Thrace. It starts from near the point of junction of Hæmus and Rhodope, and at first takes an easterly direction, the chief town which lies on its bank in the earlier part of its course being Philippopolis; but, when it reaches the still more important city of Hadrianopolis, it makes a sharp bend towards the south, and enters the sea nearly opposite the island of Samothrace. The greater part of the country is hilly and irregular, though there are considerable plains; but besides Rhodope two other tolerably definite chains intersect it, one of which descends from Hæmus to Adrianople, while the other follows the coast of the Euxine at no great distance inland. One district in the extreme northwest of Thrace lay beyond the watershed that separates the streams that flow into the Ægean from those that reach the Danube: this was the territory of Sardica, the modern Sophia. In the later Roman period two main lines of road passed through the country. One of these skirted the southern coast, being a continuation of the Via Egnatia, which ran from Dyrrhachium to Thessalonica, thus connecting the Adriatic and the Ægean; it became of the first importance after the foundation of Constantinople, because it was the direct line of communication between that city and Rome. The other followed a northwesterly course through the interior, from Constantinople by Hadrianopolis and Philippopolis to the Hæmus, and thence by Naissus (Nisch) through Mœsia in the direction of Pannonia, taking the same route by which the post-road now runs from Constantinople to Belgrade. The climate of Thrace was regarded by the Greeks as very severe, and that country was spoken of as the home of the north wind, Boreas. The coast in the direction of the Euxine also was greatly feared by sailors, as the harbors were few and the sea proverbially tempestuous; but the southern shore was more attractive to navigators, and here we find the Greek colonies of Abdera and Mesambria on the Ægean, Perinthus on the Propontis, and, the most famous of all, Byzantium, at the meeting-point of that sea and the Bosphorus. Another place which proved attractive to colonists of that race was the curious narrow strip of ground called the Thracian Chersonese, that intervened between the Hellespont and the Bay of Melas, which penetrates far into the land on its northern side. Among the cities that occupied it, Sestos and Callipolis (Gallipoli) are the most worthy of mention. In order to prevent the incursions of the Thracians, a wall was built across its isthmus, which was less than five miles in breadth. The northeastern portion of the Ægean, owing to its proximity to the coast of Thrace, was known as the Thracian Sea, and in this were situated the islands of Thasos, Samothrace, and Imbros.

There is no sufficient evidence to determine the ethnological affinities of the Thracian race. Their language has perished, and the information respecting them which has come down to us hardly furnishes more than material for conjecture, so that the most that we can affirm on the subject is that they belonged to the Indo-European family. The most striking archæological monuments of the prehistoric period are the sepulchral mounds, which have been compared in appearance to the tumulus on the plain of Marathon; these are found by thousands in various parts of the country, especially in the neighborhood of the ancient towns. As Roman implements and ornaments have been found in some of them, it is plain that this mode of burial continued to be practiced until a late period. The deity whose worship prevailed most extensively in the country was Dionysus. The most powerful Thracian tribe was that of the Odrysæ, whose king, Teres, in the middle of the 5th century B.C. extended his dominion so as to include the greater part of Thrace. During the Peloponnesian War his son Sitalces was an ally of some importance to the Athenians, because he kept in check the Macedonian monarch, who opposed the interests of the Athenians in the Chalcidic peninsula. On the death of that prince his kingdom was divided, and the power of the Thracians was consequently diminished; but in the time of Philip of Macedon we find Cersobleptes, who ruled the southeastern portion of the country, exercising an important influence on the policy of Athens. During the early period of the Roman empire the Thracian kings were allowed to maintain an independent sovereignty, while acknowledging the suzerainty of Rome, and it was not until the reign of Vespasian that the country was reduced to the form of a province. From its outlying position in the northern part of the Balkan peninsula, it was much exposed to the inroads of barbarian invaders, so that it was overrun by the Goths on several occasions, and subsequently by the Huns; but its proximity to Constantinople caused its fortunes to be closely connected with those of that city, from the time when it became the capital of the Eastern empire. In the course of time its inhabitants seem to have been thoroughly Romanized, and to have adopted the Latin language, and there is much probability in the view that they were the progenitors of the Vlachs, or Roumanians south of the Danube, whose language is of Latin origin, and who at various periods formed an important factor in the countries to the northward of Greece. The first evidence of the development of this nationality is found in a curious story told by Theophanes at the end of the 6th century. At that time a khan of the Avars had overrun the Eastern empire and appeared before the walls of Constantinople; but two generals of the imperial forces, who had concealed themselves in the Balkan, succeeded in mustering a considerable body of troops, and were on their way to surprise the rear of the Avars when their project was brought to an end by the following occurrence. One of the beasts of burden happened to fall down in the line of march, on which some one close by called out to its driver, in the language of the country, "Torna, torna, fratre," that is, "Turn him round, brother." The driver did not hear this, but the other soldiers did; and thinking the enemy were upon them, and that this was the sign for retreat, they took up the cry "Torna, torna," and the whole force fled precipitately. It seems probable that the men who used these words were Roumanian inhabitants of the Balkan. In the course of the Middle Ages the northern parts of Thrace and some other districts of that country were occupied by a Bulgarian population; and in 1361 the Ottomans, who had previously established themselves in Europe, made themselves masters of Adrianople, which for a time became the Turkish capital. When Constantinople fell in 1453, the whole country passed into the hands of the Turks, and in their possession it remained until 1878, when, in accordance with the provisions of the treaty of Berlin, the northern portion of it was placed under a separate administration, with the title of Eastern Roumelia; this province has now become, to all intents and purposes, a part of the principality of Bulgaria. The population of Thrace at the present day is composed of Turks, Greeks, and Bulgarians. (H. F. T.)

THRALE. See Piozzi.

THRASYBULUS, an Athenian who played a distinguished part in the latter years of the Peloponnesian War and in the restoration of the democracy at Athens. In 411 B.C., as an officer in the Athenian armament at Samos, he energetically opposed the oligarchical conspiracy of the Four Hundred, and was mainly instrumental in keeping the fleet and army loyal to the democracy and in procuring the recall of the banished Alcibiades. At the battle of Cynnosema, in the same year, he commanded the right wing of the Athenian fleet, and to his valor and conduct the

Athenian victory was largely due. He took an active part in the naval operations of the following years, being present at the victories of Cyzicus (410) and Arginusæ (406). In 407 he commanded a squadron on the Thracian coast, where he reduced places which had gone over to the Lacedæmonians. When the infamous Thirty Tyrants were at the height of their power in Athens, Thrasybulus, who as a democrat had been banished, marched from Thebes with about seventy men, with the connivance of Thebes, and established himself at Phyle, a strong place in the rear of Athens. There he repulsed an attack directed against him by the Thirty; his numbers increased, and, after surprising and routing a body of foot and horse, he seized Piræus, the port of Athens, but, finding the circuit of the walls too great to be defended by his small force, he retired into the adjoining Munychia. Here he was attacked by the troops of the Thirty, but in the street-fighting the democrats had the best of it, and the Thirty were in consequence deposed and retired to Eleusis. Hostilities, however, continued until Pausanias, one of the kings of Sparta, intervened, and by force and craft effected a reconciliation. The democrats marched into Athens with all the pomp of war, and sacrificed to Athene on the Acropolis. This restoration of the democracy by Thrasybulus ranked henceforward with the memorable deeds of Athenian history. To his counsels seems due in part the credit for the wise moderation with which the democrats used their victory, and the inviolate good faith with which they observed the political amnesty. The grateful citizens rewarded their champion with an olive crown. In 395, when Thebes was threatened by Sparta, the Athenians, stimulated by Thrasybulus, repaid the friendly shelter which the Thebans had afforded them in exile by resolving to stand by Thebes against Sparta, and by actually sending a force under Thrasybulus to her aid. In 390, while the war known as the Corinthian was still dragging on, Thrasybulus was sent with a fleet to check the growing power of Sparta in the Ægean. He substituted a democracy for an oligarchy at Byzantium, and won the friendship of Chalcedon; then, landing in Lesbos, he defeated a joint force of Lacedæmonians and Lesbians. In the following spring he prepared to assist Rhodes, which was threatened by the Lacedæmonians; but to recruit his forces he levied contributions from various cities. At Aspendus, in Pamphylia, an outrage committed by some of his men roused the anger of the people, who fell on him by night, and slew him in his tent. He was buried at Athens, in the Ceramicus, near the graves of Pericles and Phormio.

THREADWORMS. See NEMATOIDEA.

THREE RIVERS, the third city of Quebec province, Canada, and capital of St. Maurice county, is situated at the confluence of the rivers St. Maurice and St. Lawrence. The St. Maurice flows in from the north, and, being divided at its mouth by two islands, the channels give the town its name. It is on the line of the Canadian Pacific Railway, 78 miles southwest of Quebec, and 92 northeast of Montreal. Founded in 1634, Three Rivers is one of the oldest towns in Quebec. It is the centre of a large lumber trade, which is carried on by the St. Maurice and its tributaries. Three leagues from the city are the St. Maurice forges, where iron wares were formerly manufactured extensively. Other industries are furniture and cabinet making, boot and shoe making, and those carried on in the spool factories, brass and lead foundries, saw mills, and carriage factories. The city is the residence of the Roman Catholic bishop whose diocese bears the same name. The chief trade is in lumber, grain, cattle, etc., which find sale in South America, the West Indies, Great Britain, and the United States. The city sends one member to the Canadian House of Commons and one to the Legislative Assembly. The population of the city in 1881 was 8670 (males 4173, females 4497). The district of Three Rivers comprises the counties of St. Maurice, Nicolet, Champlain, and Maskinongé.

THROAT DISEASES. These form a large and important class, and include some of the most serious and fatal of maladies (see CROUP and DIPHTHERIA). The present article will be devoted mainly to a general account of the more common diseases affecting the upper part of the respiratory passages, but certain morbid conditions of the back of the mouth and of the gullet will also be referred to. The diagnosis of not a few of these diseases has been greatly aided by the introduction into medical practice of the laryngoscope; but, while the use of this instrument is a part of the education of every well-equipped medical practitioner, the minute investigation and the treatment of the more occult and serious maladies affecting the throat are by general consent, and with much advantage, relegated to the specialist.

Laryngitis, or inflammation of the mucous membrane of the *Larynx*, may be either acute or chronic.

Acute laryngitis is usually produced by exposure to cold directly, or by a catarrh extending either from the nasal or from the bronchial mucous membrane into that of the larynx. It is an occasional accompaniment of certain of the infectious diseases in which the throat is liable to suffer, such as small-pox, measles, scarlet fever, and erysipelas. Excessive use of the voice, as in loud speaking or singing, sometimes gives rise to laryngitis. Further, the inhalation of irritating particles, vapors, etc., and the local effects of swallowing very hot fluids, are well-recognized causes. The chief changes in the larynx are great redness, with swelling of the parts, which affect the whole interior of the cavity, but are specially marked where the tissues are lax, such as the neighborhood of the epiglottis and of the vocal chords. The effect is to produce narrowing of the channel for the entrance of air, and to this the chief dangers are due. The symptoms vary with the intensity of the attack, but, along with more or less feverishness and constitutional disturbance, there is usually a sense of heat, dryness, and pain in the throat, attended with some difficulty in the act of swallowing. Cough is a constant symptom, and is either loud, barking, or clanging, or else husky and toneless. It is at first dry, but afterwards is accompanied with expectoration. The voice, like the cough, is rough or husky. The breathing shows evidence of laryngeal obstruction, both inspiration and expiration being prolonged and difficult, with a somewhat hissing sound, and with almost no interval between the two acts. In severe cases the face and surface generally become livid, and suffocation threatens, particularly during the paroxysms of coughing. In favorable cases, which form the majority, the attack tends to abate in a few days, but on the other hand death may occur suddenly in a suffocative paroxysm, particularly in the case of children. Many cases of acute laryngitis are so comparatively slight as to make themselves known only by hoarseness and the character of the cough; nevertheless in every instance the attack demands serious attention. The treatment consists in keeping the patient in bed in an atmosphere of 60° to 70° F., made moist by steam. The use of warm gargles, and the frequent inhalation of the vapor of hot water, containing such soothing substances as benzoin, conium, hop, etc., and the application of hot fomentations to the throat, will be found of much value. Internally diaphoretics, such as small doses of antimony or Dover's powder, are also to be recommended. Such remedies usually suffice to relieve the attack, but in very severe cases more active interference may be necessary. When there is much swelling of the mucous membrane in the upper portion of the larynx, scarification of the parts with the aid of the laryngoscope may afford relief, but tracheotomy should not be neglected where death appears to be imminent from suffocation. Attacks of laryngitis may be largely prevented in those liable to them by a regimen calculated to invigorate the system, such as the cold bath, regular open-air exercise, etc.

Chronic laryngitis may occur as a result of repeated attacks of the acute form, or may arise independently from such causes as habitual exposure (especially where along with this there is over-indulgence in alcohol), the habitual overuse of the vocal organs, etc. The changes taking place in the parts are more permanent than in the acute form, consisting mainly in thickening of the mucous membrane, vocal cords, etc. With it may be ulceration, and also sometimes destruction, of the cartilaginous parts of the larynx. The symptoms vary according to the extent and amount, as well as the duration, of the inflammation. Thus there may simply be a certain huskiness or hoarseness on attempts at the use of the voice, this condition being well exemplified in the so-called clergyman's sore throat (*dysphonia clericorum*); while, on the other hand, there may be, not only complete loss of voice, but severe pain in the act of swallowing and great difficulty in breathing, accompanied sometimes with expectoration of large quantities of matter in the cases where ulceration is present. Under this variety of the disease may be included the ulceration due to syphilis and that occurring in the course of phthisis, both of which are attended with the symptoms now mentioned. The diagnosis and the treatment of all such cases is greatly aided by the use of the laryngoscope, by which a view of the affected parts can be obtained, and the proper remedies more readily applied. In the treatment of the chronic forms of laryngitis rest to the parts is essential, any attempts at continuing the use of the voice only aggravating the condition; while tonic remedies and regimen should be diligently employed to strengthen the system generally. Applications to the affected parts in the forms of solutions of silver, alum, zinc, tannin, etc., either by means of a sponge-probang introduced into the cavity or by the simpler method of spraying, are often beneficial. The insufflation of powders, such as iodoform, or starch mixed with a minute quantity of morphia, is also of service, as are likewise inhalations of vapors of iodine, carbolic acid, turpentine, eucalyptus, etc. In aggravated forms of this disease tracheotomy is occasionally necessary to relieve threatened suffocation.[1]

Symptoms similar to those already described are produced by tumors and other growths in the larynx. Such growths may be of simple character, in the form of isolated fibrous formations attached by a peduncle to some portion of the laryngeal mucous membrane, or as warty excrescences occurring upon or in the neighborhood of the vocal cords. They are detected by means of the laryngoscope, and can often be dealt with effectually by the surgeon. In the more serious malignant tumors (epitheliomatous or cancerous), which either take origin in the larynx, or spread into it from adjacent parts, interference by surgical measures can only afford temporary relief.

Certain affections of the larynx are of purely nervous origin, and occur independently of any local disease. One of the most important of these is *laryngismus stridulus*, otherwise called *child-crowing* or *spasmodic croup*. This condition occurs chiefly during the early years of childhood, often in infants during dentition, and manifests itself after premonitory symptoms of a common catarrh, lasting a day or two, by the occurrence of a violent suffocative attack due to sudden spasmodic approximation of the vocal cords, and consequent interruption to the breathing. The symptoms are not connected with any local inflammatory condition, but are the result of reflex irritation affecting the nerves supplying the laryngeal muscles. Such disturbance appears specially apt to occur in rickety or otherwise unhealthy children, in connection either with dentition or with disorders of the alimentary canal. The onset is sudden, resembling a convulsive seizure, and symptoms of suffocation are at once developed. The child makes strong efforts to inspire, which are accompanied with stridulous or crowing sounds, but, notwithstanding, very little air can enter the chest owing to the spasm of the glottis, and unless relief speedily comes death may be very rapid. In most cases, however, the attack quickly passes off, and the child seems little the worse. A liability to this disorder is sometimes observed in families, and in such instances the attacks are apt to occur in their more serious and fatal forms. Treatment to be of any avail must be promptly applied. It consists mainly in the employment of means to allay the spasm. The use of the warm bath is very serviceable for this purpose, as is also chloroform inhalation. But one of the simplest and most effectual measures is putting the finger back into the child's mouth, which is sufficient in many cases to relax the spasm of the glottis, and permit the entrance of air. In impending asphyxia the dashing of cold water over the face and chest, and the use of artificial respiration, should be tried, and even tracheotomy or laryngotomy if practicable. In all cases every effort should be made to discover any causes likely to produce nervous irritation, such as teething, intestinal worms, etc., and to deal with these by appropriate remedies.

Symptoms not unlike those now described sometimes occur in adults as the result of irritation of the recurrent laryngeal nerve, by the pressure upon it of a thoracic aneurism or other tumor. Such pressure, if long continued, results in paralysis of the nerve, occasioning more or less constant trouble in breathing.

In the condition known as *nervous aphonia*, which occurs mostly in women of hysterical habit or in circumstances of enfeebled health, the voice becomes reduced to a whisper, but there is seldom any affection of the breathing, or cough, and the laryngoscope reveals a perfectly healthy state of the parts. In such cases the remedies must be directed to the improvement of the general health. The use of electricity (faradism) applied to the neck is often attended with marked benefit.

Diseases affecting the *Trachea* are usually associated with laryngeal affections on the one hand or bronchial on the other, and their separate consideration is unnecessary.

The *Tonsils* are frequently the seat of inflammation, and *acute tonsillitis* or *quinsy* is one of the most common forms of sore throat. This affection is usually induced by cold, but it would appear to arise under other conditions also, such as digestive disturbances, etc. It is said to be more common in persons of rheumatic constitution, and one attack predisposes to others. The symptoms come on somewhat suddenly and sharply, with chill followed by fever, the temperature frequently attaining a high point of elevation. Pain is experienced in the act of swallowing from the outset. The inflammation is usually at first confined to one tonsil, but on examining the throat there is seen to be considerable redness and swelling of the whole surrounding mucous membrane, the uvula, soft palate, etc., while a copious secretion accumulates at the parts, and causes much discomfort. The act of swallowing becomes increasingly difficult, and fluids are apt to regurgitate through the nose. Pain is felt along the Eustachian tube towards the ear, and there are tenderness and swelling in the neck about the angle of the jaw on the affected side. The voice acquires a peculiar and very characteristic snuffling tone, and there may be some embarrassment to the breathing. In a few days the inflamed tonsil shows signs of suppurating, and an abscess is seen to be bulging forward into the mouth. When this bursts or is evacuated, speedy relief is obtained, and the patient is soon restored to his usual health. Occasionally, however, the inflammation passes from the one tonsil to the other, and a similar experience has to be gone through again. An attack of quinsy rarely lasts beyond a week or ten days, and is not as a rule attended with danger to life, although it is said that suffocation has occasionally occurred owing to the bursting of a large tonsillar abscess during sleep, and the passage of its contents into the trachea. The treatment for a quinsy is much the same as that for an ordinary catarrh or cold,—confinement to the house, the employment of diaphoretics or mild laxatives, together with light diet, being all that is necessary as regards general management. For the relief of the local inflammation the frequent employment of warm gargles of milk and water or glycerin and water or the inhalation of vapor afford much relief, as do also hot applications to the neck. Some authorities recommend the sucking of ice and the external application of cold compresses, but on the whole warmth appears to be the more soothing remedy. When an abscess has formed it may be punctured, but care requires to be observed in doing this that no injury be inflicted on any important bloodvessel.

The tonsils are frequently the seat of permanent enlargement (*chronic tonsillitis*), which may result from frequent attacks of quinsy or may exist independently. They are often seen in delicate young people, and, in the case of some at least, denote a strumous tendency. They give trouble from the mechanical impediment they present to swallowing and clear articulation, and when very large they cause the breathing to be more or less noisy at all times, but especially during sleep, while again they may give rise to a measure of deafness. They are treated by remedies which promote the general nutrition, such as cod-liver oil, iron, etc., by the use of astringent gargles, and when necessary by excision.

The *pharynx* or upper portion of the gullet (seen to a large extent on looking at the back of the mouth) is frequently the seat of a chronic inflammatory condition, usually associated with derangements of the digestive organs, and sometimes the result of excessive tobacco smoking. On inspection the mucous membrane is seen to be unduly red and glazed looking, with the enlarged follicles standing out prominently. It produces considerable irritation, cough, and discomfort, which may be of long continuance unless subjected to appropriate treatment. This consists in removing any local source of irritation, in rectifying by diet and other remedies (see STOMACH DISEASES) any gastric disturbance, and by the application to the parts of silver or other mild caustic solution.

The *Œsophagus* or gullet may be the seat of catarrhal or inflammatory conditions, but the more important ailments affecting this tract are those which arise from local injuries, such as the swallowing of scalding or corrosive substances. This may cause ulceration followed with cicatrization which narrows the passage and produces the symptoms of stricture of the œsophagus,—namely, pain and difficulty in swallowing, with regurgitation of the food. The severity of the case will necessarily depend upon the amount of narrowing and consequent mechanical obstruction, but in some instances this has occurred to such an extent as practically to occlude the canal. Cases of œsophageal stricture of the kind now referred to may sometimes be relieved by the diligent use of the bougie, but not unfrequently, in order to prevent death by starvation, surgical interference is requisite to form an opening into the stomach by means of which food may be introduced.

---

[1] [Chronic laryngitis with necrosis of the laryngeal cartilages and stenosis of the larynx rendered tracheotomy necessary in the case of Frederick III. of Germany. The operation was done by Dr. Bramann, February 9, 1888, relieving impending suffocation and prolonging life.—AM. ED.]

A still more serious and frequent cause of œsophageal stricture is that due to cancerous growth in the canal, which may occur at any part, but is most common at the lower end, in the vicinity of the entrance into the stomach. The symptoms of this condition are increasing difficulty in the passage downwards of the food, the steady decline in strength, and the development of the cancerous cachexia, together with enlargements of the glands in the neck; while the diagnosis is rendered the more certain by the absence of any cause, such as local injury, for the formation of a stricture, and by the age (as a rule at or beyond middle life). Treatment here can only be palliative while life continues, which in general is not long. Feeding by the bowel (enemata) may be advantageously resorted to as supplementary to efforts to administer liquid nutriment in the usual way. It is to be observed in all cases of organic stricture that the food does not necessarily return at once, but seems as if it had passed into the stomach. In reality, however, it has passed into the dilated or pouched portion of the canal, which is almost always present immediately above the seat of stricture, where it remains until, from its amount, it regurgitates back into the mouth, when it can be seen, by the absence of any evidence of digestion, that it has never been within the cavity of the stomach. While in this way a large quantity of the food returns, it often happens that a small amount of the liquid portion does trickle through the narrowed canal into the stomach, and thus life may be prolonged for a considerable time.

Strictures of the œsophagus may also be produced by the pressure of tumors or aneurisms within the cavity of the chest but external to the canal. Further, a variety of œsophageal stricture is not unfrequently met with which is due entirely to nervous causes, and is quite unconnected with organic disease,—namely, that form occurring in hysterical females termed spasmodic stricture. Here the attack of difficulty in swallowing comes on usually when the patient is at meals, and the food cannot pass down. The absence, however, of all history of any organic source of disease, and especially the perfect facility with which the œsophageal tube or bougie is passed, together with other manifestations of hysteria commonly present, serve readily to establish the diagnosis. The remedies most suitable are tonics and the frequent passage of the stomach-tube, which as a rule soon entirely removes the tendency to spasm.

Finally, difficulty in swallowing sometimes occurs in certain serious nervous diseases from paralysis affecting the nerves supplying the muscular coats of the œsophagus, which thus loses its propulsive power. When such complications occur they usually denote an advanced stage of the central disease with which they are connected, and a speedily fatal termination. (J. O. A.)

THRONDHJEM, or TRONDHJEM (DRONTHEIM), the third town of Norway, capital of the Throndhjem stift and of the South Throndhjem amt, is pleasantly situated on the southern shore of the Throndhjem fjord, at the mouth of the Nid, 348 miles by rail to the north of Christiania, in 63° 25′ 52″ N. lat. and 10° 33′ 19″ E. long. In front of the town is the islet of Munkholm, formerly a monastery and now a fortress; on the high ground to the east is the small stronghold of Christiansten. The houses of Throndhjem, principally of wood, are substantial, spacious, and well lighted; and the streets are wide, regular, and scrupulously clean. The principal building is the cathedral, partly dating from about 1090, but chiefly belonging to the 12th and 13th centuries (*c.* 1161–1248). Its extreme length was 325 feet and its extreme breadth 124 feet; but in the 14th, 15th, and 17th centuries it suffered greatly from repeated fires; after the last of these the nave was completely abandoned, and soon became a heap of ruins. The building, which still ranks as the finest ecclesiastical edifice in Norway, and is the place of coronation of the Norwegian sovereigns, is now undergoing extensive but judicious restoration. The workmanship of its eastern windows and of the marble or steatite columns of the choir is specially noteworthy. Throndhjem possesses three churches in all, and among its other public buildings may be mentioned the residences of the stiftsamtmand and the bishop, the grammar school, the real school, the head office of the Bank of Norway, the deaf and dumb institute, the hospital, and the theatre. It is the seat of the royal Norwegian scientific society, in connection with which are an excellent library and a good zoological and antiquarian museum. Throndhjem, which has steamboat communication with Christiania, Hamburg, and Hull, and is connected with Sweden by the Meraker Railway (63 miles), carries on an extensive trade in copper (from the Röros mines), timber, oil, and dried and salted fish; the industries include shipbuilding, sawmilling, distilling, tanning, rope-making and ribbon-making. The population in 1875 was 22,152; in 1885 it was estimated at 24,000.

Throndhjem, originally Nidaros, was founded by Olaf Tryggvason, who built a royal residence and a church here in 996. It was made an archbishopric in 1152. The city attained its highest development about the latter half of the 13th century, by which time it had become an important pilgrimage centre and had as many as fifteen churches. It has sustained frequent sieges, as well as devastating conflagrations. Its importance declined about the time of the Reformation, when it ceased to be a resort of pilgrims. At the beginning of the present century its inhabitants numbered only 8832.

THRUSH (A. S. *þrysce*, Icel. *þröstr*, Norw. *Trast*, O. H. Germ. *Drosce*, whence the modern German *Drossel*, to be compared with the analogous English form THROSTLE.[1] now almost obsolete, both being apparently diminutives), the name that in England seems to have been common to two species of birds, the first now generally distinguished as the Song-Thrush, but known in many districts as the Mavis,[2] the second called the Mistletoe-Thrush, but having many other local designations, of which more presently.

The former of these is one of the finest songsters in Europe, but it is almost everywhere so common that its merits in this respect are often disregarded, and not unfrequently its melody, when noticed, is ascribed to the prince of feathered vocalists, the NIGHTINGALE (vol. xvii. p. 511–12). The Song-Thrush is too well known to need description, for in the spring and summer there is hardly a field, a copse, or a garden that is not the resort of a pair or more; and the brown-backed bird with its spotted breast, hopping over the grass for a few yards, then pausing to detect the movement of a worm, and vigorously seizing the same a moment after, is one of the most familiar sights. Hardly less well known is the singular nest built by this bird—a deep cup lined with a thin but stiff coating of fragments of rotten wood ingeniously spread, and plastered so as to present a smooth interior—in which its sea-green eggs spotted with black are laid. An early breeder, it builds nest after nest during the season, and there can be few birds more prolific. Its ravages on ripening fruits, especially strawberries and gooseberries, excite the enmity of the imprudent gardener who leaves his crops unprotected by nets, but he would do well to stay the hand of revenge, for no bird can or does destroy so many snails, as is testified to the curious observer on inspection of the stones that it selects against which to dash its captures,—stones that are besmeared with the slime of the victims and bestrewn with the fragments of their shattered shells. Nearly all the young Thrushes reared in the British Islands—and this expression includes the storm-swept isles of the Outer Hebrides, though not those of Shetland—seem to emigrate as soon as they are fit to journey, and at a later period they are followed by most of their parents, so that many parts of the kingdom are absolutely bereft of this species from October to the end of January. On the continent of Europe the autumnal influx of the birds bred in the North is regarded with much interest, as has been already stated (BIRDS, vol. iii. pp. 663–4), for they are easily ensnared and justly esteemed for the table, while their numbers make their appearance in certain districts a matter of great importance.

---

[1] For many interesting facts connected with the words "Thrush" and "Throstle" which cannot be entered upon here, the reader should consult Prof. Skeat's *Etymological Dictionary*.

[2] Cognate with the French *Mauvis*, though that is nowadays almost restricted to the REDWING (vol. xx. p. 331). Its diminutive is *Mauviette*, the modern table-name of the Skylark, and perhaps *Mavis* was in English originally the table-name of the Thrush.

The second species to which the name applies is distinguished as the Mistletoe-Thrush, or, by corrupt abbreviation, the Missel-Thrush.[1] It is known also in many districts as the "Storm-cock," from its habit of singing in squally weather that silences almost all other birds, and "Holm- (*i.e.*, Holly-) Thrush," while the harsh cries it utters when angry or alarmed have given it other local names, as "Screech," "Shrite," and "Skrike," all traceable to the Anglo-Saxon *Scric.*[2] This is a larger species than the last, of paler tints, and conspicuous in flight by the white patches on its outer tail-feathers. Of bold disposition, and fearless of the sleety storms of spring, as of predatory birds, the cock will take his stand on a tall tree, "like an enchanter calling up the gale" (as Knapp happily wrote), and thence with loud voice proclaim in wild and discontinuous notes the fervor of his love for his mate; nor does that love cease when the breeding-season is past, since this species is one of those that appear to pair for life, and even when, later in the year, it gathers in small flocks, husband and wife may be seen in close company. In defence of nest and offspring, too, few birds are more resolute, and the Daw, Pie, or Jay that approaches with an ill intent speedily receives treatment that causes a rapid retreat, while even the marauding cat finds the precincts of the "master of the coppice" (*Pen y llwyn*), as the Welsh name this Thrush, unsuitable for its stealthy operations. The connection of this bird with the mistletoe, which is as old as the days of Aristotle, is no figment, as some have tried to maintain. Not only is it exceedingly fond of the luscious viscid berries, but it seems to be almost the only bird that will touch them. Of other British Thrushes, the FIELDFARE (vol. ix. p. 124), REDWING (vol. xx. p. 331), and the Blackbird and Ring-OUSEL (vol. xviii. p. 78) have been before noticed in these pages, as has been (under the first of those headings) the so-called "Robin" of North America.

The Thrushes have been generally considered to form a distinct Family, *Turdidæ*, which is placed by some taxonomers the highest in rank among birds. An attempt has already been made (ORNITHOLOGY, vol. xviii. pp. 34, 51) to point out the fallacy of this view, and space is here wanting to dwell longer on the matter. This is the more to be regretted, for, though many modern systematists will admit the close connection of the *Turdidæ* and some of the so-called Family *Sylviidæ* or WARBLERS (*q.v.*), the abolition or modification of the latter, by wholly or partially merging it in the former, has not yet been satisfactorily effected, and Mr. Seebohm, in his portion of the British Museum *Catalogue of Birds* (v. p. 1), being compelled by the conditions previously laid down by Mr. Sharpe (*op. cit.*, iv. pp. 6, 7) to unite them, protests against doing so. His own assignment of the Subfamily *Turdinæ* is into 11 genera, of which, however, 6 only would be commonly called Thrushes, and it must be borne in mind that in establishing these he regards coloration as the most valid character. They are *Geocichla* with 40 species, *Turdus* with 48, *Merula* with 52, *Mimocichla* with 3, *Catharus* with 12, and *Monticola* with 10. These last, well known as Rock-Thrushes, make a very near approach to the NIGHTINGALE (vol. xvii. pp. 511–12), REDSTART (vol. xx. pp. 330–31), and WHEATEAR (*q.v.*). (A. N.)

THUCYDIDES. Thucydides was the greatest historian of antiquity, and, if not the greatest that ever lived, as some have deemed him, at least the historian whose work is the most wonderful, when it is viewed relatively to the age in which he did it. The most important facts which we know about him are those which he has told us himself. It matters very little, fortunately, that the biographical materials are scanty. For posterity, his life is represented by his life's labor, the *History of the Peloponnesian War*; and the biographical facts are of interest chiefly as aids to the appreciation of that history. He was probably born in or about 471 B.C. The only definite testimony on the subject is contained in a passage of Aulus Gellius, who says that in 431 Hellanicus "seems to have been" sixty-five years of age, Herodotus fifty-three, and Thucydides forty (*Noct. Att.*, 15, 23). The authority for this statement was Pamphila, a compiler of biographical and historical notices, who lived in the reign of Nero. She must have had access to Greek sources of the 4th century B.C.; and her precision—though qualified, in the version of Gellius, by the word "seems"—would warrant the supposition that she had taken some pains to secure accuracy. Further, the date which she assigns is in good accord with an inference fairly deducible from the language of Thucydides himself, viz., that in 431 he had already reached the full maturity of his powers. Krüger, indeed, would place his birth earlier than 471, and Ullrich later, but for reasons, in each case, which can scarcely outweigh the ancient authority.

Date of birth.

Parentage.

The parentage of Thucydides was such as to place him in a singularly favorable position for the great work to which he afterwards devoted his life. His father Olorus, a citizen of Athens, belonged to a family which derived wealth and influence from the possession of gold mines at Scaptesyle, on the Thracian coast opposite Thasos, and was a relative of his elder namesake, the Thracian prince whose daughter Hegesipyle married the great Miltiades, so that Cimon, son of Miltiades, was a cousin, perhaps first cousin, once removed, of Thucydides. It was in the vault of the Cimonian family at Athens, and near the remains of Cimon's sister Elpinice, that Plutarch saw the grave of Thucydides. Thus the fortune of birth secured three signal advantages to the future historian: he was rich; he had two homes—one at Athens, the other in Thrace,—no small aid to a comprehensive study of the conditions under which the Peloponnesian War was waged; and his family connections were likely to bring him from his early years into personal intercourse with the men who were shaping the history of his time.

The years 471–431 B.C.

The development of Athens during the forty years from 471 to 431 was, in itself, the best education which such a mind as that of Thucydides could have received. In the first two decades of his life the expansion and consolidation of Athenian power was proceeding; between his twentieth and fortieth year the inner resources of the city were being applied to the embellishment and ennoblement of Athenian life. As Cimon had been the principal agent in the former period, so Pericles was the central figure of the latter. A consciousness of such periods may be traced in the passage of the Funeral Oration where Pericles refers, first, to the acquisition of empire by the preceding generation, and then to the improvement of that inheritance by his own contemporaries (ii. 36, 5). It is a natural subject of regret, though it is not a just cause of surprise or complaint, that the History tells us nothing of the literature, the art, or the social life under whose influences its author had grown up. The Funeral Oration contains, indeed, his general testimony to the value and the charm of those influences. There we have the very essence of the Athenian spirit condensed into a few pregnant sentences, which show how thoroughly the writer was imbued with that spirit, and how profoundly he appreciated its various manifestations. But he leaves us to supply all examples and

Inner life of Athens.

---

[1] There is no doubt of the bird taking its name from the plant Mistletoe (*Viscum album*), about the spelling of which there can be no uncertainty—A. S. *Misteltan*, the final syllable originally signifying "twig," and surviving in the modern "time," as of a fork or of a deer's antler.

[2] It seems quite possible that the word SHRIKE (vol. xxi. p. 885), though now commonly accepted as the equivalent, in an ornithological sense, of *Lanius*, may have been originally applied to the Mistletoe-Thrush. In several of the Anglo-Saxon *Vocabularies* dating from the 8th to the 11th century, as printed by Thomas Wright, the word *Scric*, which can be hardly anything else than the early form of "Shrike," is glossed *Turdus*.

Limit to the scope of the History.

details for ourselves. Beyond a passing reference to public "festivals," and to "beautiful surroundings in private life," he makes no attempt to define those "recreations for the spirit" which the Athenian genius had provided in such abundance. No writer of any age, perhaps, has rendered a more impressive tribute to the power of the best art than is implied in the terse phrase of Thucydides, when, speaking of the works which the Athenian daily saw around him, he declares that "the daily delight of them banishes gloom" (ὧν καθ' ἡμέραν ἡ τέρψις τὸ λυπηρὸν ἐκπλήσσει). But it is not to Thucydides that we owe any knowledge of the particular forms in which that art was embodied. He alludes to the newly-built Parthenon only as containing the treasury; to the statue of Athene Parthenos which it enshrined, only on account of the gold which, at extreme need, could be detached from the image; to the Propylæa and other buildings with which Athens had been adorned under Pericles, only as works which had reduced the surplus of funds available for the war. Among the illustrious contemporaries whose very existence would be unknown from his pages are the dramatists Æschylus, Sophocles, Euripides, Aristophanes; the architect Ictinus; the sculptor Phidias; the physician Hippocrates; the philosophers Anaxagoras and Socrates. If Thucydides had mentioned Sophocles as a general in the Samian War, it may be doubted whether he would have noticed the circumstance that Sophocles also wrote dramas, unless it had been for the purpose of distinguishing him from a namesake. And, had he lived to carry his story down to the debate in the Athenian ecclesia after the battle of Arginusæ, we may conjecture that Socrates, if named at all, would have been barely mentioned as the one prytanis out of fifty who resisted an unconstitutional act,—with some expression, perhaps, of praise, but without any fuller characterization. We think of the countless occasions which Herodotus, if he had dealt with this period, would have found for invaluable digressions on men and manners, on letters and art; we feel the severity of the loss which the reticence of Thucydides has caused to us; and we might almost be tempted to ask whether the more genial, if laxer, method of Herodotus does not indeed correspond better with a liberal conception of the historian's office. No one can do full justice to Thucydides, or appreciate the true completeness of his work, who has not faced this question, and found the answer to it. It would be a hasty judgment which inferred from the omissions of the History that its author's interests were exclusively political. Thucydides was not writing the history of a period. His subject was an event—the Peloponnesian War,—a war, as he believed, of unequalled importance, alike in its direct results and in its political significance for all time. To his task, thus defined, he brought an intense concentration of all his faculties. He worked with a constant desire to make each successive incident of the war as clear as possible. To take only two instances: there is nothing in literature more graphic than his description of the plague at Athens, or than the whole narrative of the Sicilian expedition. But the same temper made him resolute in excluding irrelevant topics. The social life of the time, the literature and the art, find no place in his picture simply because they did not belong to his subject. His work was intended to be "a possession forever." He could conceive a day when Sparta should be desolate, and when only ruins of Athens should remain. But his imagination never projected itself into a time when the whole fabric of Hellenic civilization should have perished. Could his forecast have extended to an age when men of "barbarian" races and distant climes would be painfully endeavoring to reconstruct a picture of that civilization,—when his own narrative would need the help of side-lights which seemed to him wholly unnecessary,—then, assuredly, he would have added all that such readers could require. But he would not have done this in the manner of Herodotus, by free indulgence in digression; rather he would have gathered up the social and intellectual phenomena of his day in a compact and systematic introduction, specially designed for the non-Hellenic reader.

Thucydides and Antiphon.

Style of Thucydides.

The biography which bears the name of Marcellinus states that Thucydides was the disciple of Anaxagoras in philosophy and of Antiphon in rhetoric. Such statements were often founded on nothing more than a desire to associate distinguished names, and to represent an eminent man as having profited by the best instruction in each kind which his contemporaries could afford. In this case there is no evidence to confirm the tradition. But it may be observed that Thucydides and Antiphon at least belong to the same rhetorical school, and represent the same early stage of Attic prose. Both writers use words of an antique or decidedly poetical cast; both point verbal contrasts by insisting on the precise difference between terms of similar import; and both use metaphors somewhat bolder than were congenial to Greek prose in its riper age. The differences, on the other hand, between the style of Thucydides and that of Antiphon arise chiefly from two general causes. First, Antiphon wrote for hearers, Thucydides for readers; the latter, consequently, can use a degree of condensation, and a freedom in the arrangement of words, which would have been hardly possible for the former. Again, the thought of Thucydides is often more complex than any which Antiphon undertook to interpret; and the greater intricacy of the historian's style exhibits the endeavor to express each thought.[1] Few things in the history of literary prose are more interesting than to watch that vigorous mind in its struggle to mould a language of magnificent but immature capabilities. The obscurity with which Thucydides has sometimes been reproached often arises from the very clearness with which a complex idea is present to his mind, and his strenuous effort to present it in its entirety, when the strong consciousness of logical coherence will make him heedless of grammatical regularity. He never sacrifices the thought to the language, but he will sometimes sacrifice the language to the thought. A student of Thucydides may always be consoled by the reflection that he is not engaged in unravelling a mere rhetorical tangle. Every light on the sense will be a light on the words; and, when, as is not seldom the case, Thucydides comes victoriously out of this struggle of thought and language, having achieved perfect expression of his meaning in a sufficiently lucid form, then his style rises into an intellectual brilliancy—thoroughly manly, and also penetrated with intense feeling—which nothing in Greek prose literature surpasses.

His relation to public life.

430.

The plague.

The History shows not only a thorough insight into the political ideas of Pericles, but also a sympathy with him, and an admiration for his character, which indicate personal friendship. If, before 431, Thucydides had wished to take a prominent part in the public life of Athens, everything was in his favor. But there is no trace of his having done so; and it is possible that his opportunities in this respect were modified by the necessity of frequent visits to Thrace, where the management of such an important property as the gold mines must have claimed the occasional presence of the proprietor. The manner in which he refers to his personal influence in that region is such as to suggest that he had sometimes resided there (iv. 105. 1). He was at Athens in the spring of 430, when the plague broke out. If his account of the symptoms has not enabled physicians to agree on a diagnosis of the malady, it is at least singularly full and vivid. He had himself been attacked by the plague; and, as he briefly adds, "he had seen others suffer." The tenor of his narrative would warrant the inference that he had been one of a few who were active in ministering to the sufferers—in that fearful time when religion and morality lost all control over the despairing population of Athens—when all the ordinary decencies of life were set at nought, and when even the nearest relatives failed in the duties of humanity towards the dying.

---

[1] See Jebb's *Attic Orators*, vol. i. p. 85.

424.

The turning-point in the life of Thucydides came in the winter of the year 424. He was then forty-seven (if his birth had been rightly placed in 471), and for the first time he is found holding an official position. He was one of two generals entrusted with the command of the regions towards Thrace (τὰ ἐπὶ Θρᾴκης), a phrase which denotes the whole Thracian seaboard from Macedonia eastward to the vicinity of the Thracian Chersonese, though often used with more special reference to the Chalcidic peninsula. One reason why Thucydides had been chosen for the post was the local influence which he possessed among the people of the Thracian seaboard, through his family connections and his ownership of the gold mines. His colleague in the command was Eucles. About the end of November, 424, Eucles was in the city of Amphipolis, on the river Strymon. That city was not merely more important to Athens than any other place in the region,—it was the stronghold of Athenian power in the north. To guard it with all possible vigilance was a matter of peculiar urgency at that moment. The ablest of Spartan leaders, Brasidas, was then in Thrace with a Peloponnesian army,—not, indeed, close to Amphipolis, but still within a distance which imposed special caution on Athenian officers. He was in the Chalcidic peninsula, where he had already gained rapid success; and part of the population between that peninsula and Amphipolis was already known to be disaffected to Athens. Under circumstances so suggestive of possible danger, we might have expected that Thucydides, who had seven ships of war with him, would have been near his colleague Eucles, and ready to co-operate with him at a moment's notice. It appears, however, that, with his ships, he was at the island of Thasos, several miles distant from the Thracian coast. Brasidas, making a forced march from the Chalcidic peninsula, suddenly appeared before Amphipolis. Eucles sent in all haste for Thucydides, who arrived with his ships from Thasos just in time to beat off the enemy from Eion at the mouth of the Strymon, but not in time to save Amphipolis. Only a few hours before, it had capitulated to Brasidas, who had offered exceptionally favorable terms. The profound vexation and dismay felt at Athens found expression in the punishment of the commander who seemed primarily responsible for so grave a disaster. For the next twenty years—*i.e.*, till 404—Thucydides was an exile from Athens. It is not improbable that the charge brought against him was that of treason (προδοσία), for which the penalty was death, and that he avoided this penalty by remaining in banishment. A special *psephism* is said to have been required before Thucydides could return in 404, which would have been regular if a capital sentence had been on record against him, but not so if he had been merely under sentence of exile. Cleon is said to have been the prime mover in his condemnation; and this is likely enough. Eucles was probably punished also. Grote was the first modern writer to state the reasons for thinking that Thucydides may have been really guilty of culpable negligence on this occasion, and that his punishment—which had usually been viewed as the vindictive act of a reckless democracy—may have been well deserved. Everything turns on the question why he was at Thasos just then, and not at Eion. No one disputes that, after the summons from Eucles, he did all that was possible. It is true that the facts of the situation, so far as we know them, strongly suggest that he ought to have been at Eion, and do not disclose any reason for his being at Thasos. But it is only fair to remember, in a case of this kind, that there may have been other facts which we do not know. There is some presumptive evidence of carelessness; but we can hardly say more than that. The absence of Thucydides from the neighborhood of Amphipolis at that precise juncture may have had some better excuse than now appears.

Fall of Amphipolis.

Exile of Thucydides.

423–404.

Travels.

From 423 to 404 the home of Thucydides was on his property in Thrace, but much of his time appears to have been spent in travel. He visited the countries of the Peloponnesian allies,—recommended to them by his quality as an exile from Athens; and he thus enjoyed the rare advantage of contemplatimg the great war from a point of view opposite to that at which he had previously been placed. He speaks of the increased leisure which his banishment secured to his study of events. He refers partly, doubtless, to detachment from Athenian politics, partly, also, we may suppose, to the opportunity of visiting places signalized by recent events, and of examining their topography in the light of such information as he could collect on the spot. The local knowledge which is often apparent in his Sicilian books may have been acquired at this period. The banishment of Thucydides was the most fortunate event that could have occurred for him and for us, when it enabled him, in this way, to look at his subject all round. If it is always hard for an historian to be impartial, it is especially so for the historian of a great war in which his own country has been one of the combatants. The mind of Thucydides was naturally judicial, and his impartiality — which seems almost superhuman by contrast with Xenophon's *Hellenica*—was in some degree a result of temperament. But it cannot be doubted that the evenness with which he holds the scales was greatly assisted by the experience which, during these years of exile, must have been familiar to him—that of hearing the views and aims of the Peloponnesians set forth by themselves, and of estimating their merits otherwise than would have been easy for an observer in a hostile camp.

404.

Return to Athens.

His own words make it clear that he returned to Athens, at least for a time, in 404. Classen supposes that his return took place in the autumn of that year, about six months after Athens had surrendered to Lysander, and while the Thirty were still in power. Finding that the rule of the oligarchy was becoming more and more violent, Thucydides again left Athens, and retired to his property in Thrace, where he lived till his death, working at his History. The preponderance of testimony certainly goes to show that he died in Thrace, and by violence. It would seem that, when he wrote chapter 116 of his third book, he was ignorant of an eruption of Etna which took place in 396. There is some reason then, for believing that he did not survive his seventy-fifth year. According to ancient tradition, he was killed by robbers. His relics were brought to Athens, and laid in the vault of Cimon's family, where Plutarch saw their resting-place. The abruptness with which the History breaks off agrees with the story of a sudden death. The historian's daughter is said to have saved the unfinished work, and to have placed it in the hands of an editor. This editor, according to one account, was Xenophon, to whom Diogenes Laertius assigns the credit of having "brought the work into reputation, when he might have suppressed it." The tradition is, however, very doubtful. In its origin, it may have been merely a guess, suggested by a feeling that no one then living could more appropriately have discharged the office of literary executor than the writer who, in his *Hellenica*, continued the narrative.

Death: before 396 B.C. (?).

Conception of the History. At the outset of the History Thucydides has indicated his general conception of his work, and has stated the principles which governed its composition. His purpose had been formed at the very beginning of the war, in the conviction that it would prove more important than any event of which Greeks had record. The leading belligerents, Athens and Sparta, were both in the highest condition of effective equipment. The whole Hellenic world—including Greek settlements outside of Greece proper—was divided into two parties, either actively helping one of the two combatants or meditating such action. Nor was the movement confined within even the widest limits of Hellas: the "barbarian" world also was affected by it,—the non-Hellenic populations of Thrace, Macedonia, Epirus, Sicily, and finally, the Persian kingdom itself. **Permanent interest of the war.** The aim of Thucydides was to preserve an accurate record of this war, not only in view of the intrinsic interest and importance of the facts, but also in order that these facts might be permanent sources of political teaching to posterity. His hope was, as he says, that his History would be found profitable by "those who desire an exact knowledge of the past as a key to the future, which in all probability will repeat or resemble the past. The work is meant to be a possession forever, not the rhetorical triumph of an hour." As this context shows, the oft quoted phrase, "a possession forever," had, in its author's meaning, a more definite import than any mere anticipation of abiding fame for his History. It referred to the permanent value of the lessons which his History contained. Thucydides stands alone among the men of his own days, and has no superior of any age, in the width of mental grasp which could seize the general significance of particular events. The political education of mankind began in Greece, and in the time of Thucydides their political life was still young. Thucydides knew only the small city-commonwealth on the one hand, and on the other the vast barbaric kingdom; and yet, as has been well said of him, "there is hardly a problem in the science of government which the statesman will not find, if not solved, at any rate handled, in the pages of this universal master."[1]

Such being the spirit in which he approached his task, it is interesting to inquire what were the points which he himself considered to be distinctive in his method of executing it. His Greek predecessors in the recording of events had been, he conceived, of two classes. **The epic poets.** First, there were the epic poets, with Homer at their head, whose characteristic tendency, in the eyes of Thucydides, is to exaggerate the greatness or splendor of things past—as, for instance, conceding the historical character of the Trojan war, he supposes the strength of the Greek fleet to be overstated in the *Iliad*. **The prose chroniclers.** Secondly, there were the Ionian prose writers whom he calls "chroniclers" (λογογράφοι). These writers are directly known to us only by meagre fragments; but Dionysius of Halicarnassus has described their general characteristics in a manner which serve to illustrate the differences indicated by Thucydides between their work and his own. Their general object was to diffuse a knowledge of legends preserved by oral tradition, and of written documents—usually lists of officials or genealogies—preserved in public archives; and they published their materials as they found them, without any attempt at sifting fact from fable. Thucydides describes their work by the word ξυντιθέναι, but his own by ξυγγράφειν,—the difference between the terms answering to that between compilation of a somewhat mechanical kind and historical composition in a higher sense. The vice of the "chroniclers," in his view, is that they cared only for popularity, and took no pains to make their narratives trustworthy. In contrast with these predecessors, Thucydides has subjected his materials to the most searching scrutiny. **Distinctive aim of Thucydides.** The ruling principle of his work has been strict adherence to carefully verified facts. "As to the deeds done in the war, I have not thought myself at liberty to record them on hearsay from the first informant or on arbitrary conjecture. My account rests either on personal knowledge or on the closest possible scrutiny of each statement made by others. The process of research was laborious, because conflicting accounts were given by those who had witnessed the several events, as partiality swayed or memory served them."

Herodotus and Thucydides. A period of at least twenty years must have elapsed between the date at which Herodotus ceased to write and that at which the History of Thucydides received its present form. There can be no doubt that Thucydides knew the History of Herodotus, and that in some places he alludes to it. The diligence and the honesty of Herodotus are alike beyond question, and would, we may be sure, have been fully recognized by Thucydides. The work of Herodotus was distinct in kind from that of the Ionian chroniclers, and was of an immeasurably higher order. While they dealt, in a bold fashion, with the annals of separate cities or peoples, Herodotus set the first example of multifarious knowledge subordinated to the execution of a great historical plan, and also showed for the first time that a prose history could have literary charm. But Thucydides doubtless thought of Herodotus as having certain traits in common with the Ionian chroniclers, and as being liable, so far, to the same criticism. One such trait would be the inadequate sifting of evidence; another, the mixture of a fabulous element with historical fact; and another, perhaps, the occasional aiming at rhetorical effect. Of this last trait the chief instances would be those imaginary dialogues or speeches with which Herodotus sometimes enlivens his narrative. This brings us to an important topic,—the purpose with which Thucydides himself has admitted speeches into his History, and the manner in which they have been composed.

The speeches. The speeches constitute between a fourth and a fifth part of the History. If they were eliminated, an admirable narrative would indeed remain, with a few comments, usually brief, on the more striking characters and events. But we should lose all the most vivid light on the inner workings of the Greek political mind, on the motives of the actors, and the arguments which they used,—in a word, on the whole play of contemporary feeling and opinion. To the speeches is due in no small measure the imperishable intellectual interest of the History, since it is chiefly by the speeches that the facts of the Peloponnesian War are so lit up with keen thought as to become illustrations of general laws, and to acquire a permanent suggestiveness for the student of politics. When Herodotus made his persons hold conversations or deliver speeches, he was following the precedent of epic poetry; his tone is usually colloquial rather than rhetorical; he is merely making thought and motive vivid in the way natural to a simple age. Thucydides is the real founder of the tradition by which historians were so long held to be warranted in introducing set speeches of their own composition. **Their language.** His own account of his practice is given in the following words. "As to the speeches made on the eve of the war, or in its course, I have found it difficult to retain a memory of the precise words which I had heard spoken; and so it was with those who brought me reports. But I have made the persons say what it seemed to me most opportune for them to say in view of each situation; at the same time I have adhered as closely as possible to the general sense of what was actually said." So far as the language of the speeches is concerned, then, Thucydides plainly avows that it is mainly or wholly his own. As a general rule, there is little attempt to mark different styles. The case of Pericles, whom Thucydides must have repeatedly heard, is probably an exception; the Thucydidean speeches of Pericles offer several examples of that bold imagery which Aristotle and Plutarch agree in ascribing to him, while the Funeral Oration, especially, has a certain majesty of rhythm, a certain union of impetuous movement with lofty grandeur, which the historian has given to no other speaker. Such strongly marked characteristics as the curt bluntness of the Spartan ephor Sthenelædas, or the insolent vehemence of Alcibiades are also indicated. But the dramatic truth of the speeches generally resides in the matter, not in the form. **Their matter.** In regard to those speeches which were delivered at Athens before his banishment in 424,—and seven such speeches are contained in the History,—Thucydides could rely either on his own recollection or on the sources accessible to a resident citizen. In these cases there is good reason to believe that he has reproduced the substance of what was actually said. In other cases he had to trust to more or less imperfect reports of the "general sense;" and in some instances, no doubt, the speech represents simply his own conception of what it would have been "most opportune" to say. The most evident of such instances occur in the addresses of leaders to their troops, **The military speeches.** The historian's aim in these military harangues which are usually short, is to bring out the points of a strategical situation; a modern writer would have attained the object by comments prefixed or subjoined to his account of the battle. The comparative indifference of Thucydides to dramatic verisimilitude in these military orations is curiously shown by the fact that the speech of the general on the one side is sometimes as distinctly a reply to the speech of the general on the other as if they had been delivered in debate. We may be sure, however, that, wherever Thucydides had any

Voltaire's criticism.

The Greek view.

authentic clew to the actual tenor of a speech, he preferred to follow that clew rather than to draw on his own invention. Voltaire has described the introduction of set speeches as "a sort of oratorical falsehood, which the historian used to allow himself in old times." The strongest characteristic of Thucydides is his devotion to truth,—his laborious persistence in separating fact from fiction; and it is natural to ask why he adopted the form of set speeches, with the measure of fiction which it involved, instead of simply stating, in his own person, the arguments and opinions which he conceived to have been prevalent. The question must be viewed from the standpoint of a Greek in the 5th century B.C. Epic poetry had then for many generations exercised a powerful influence over the Greek mind. Homer had accustomed Greeks to look for two elements in any complete expression of human energy,—first, an account of a man's deeds, then an image of his mind in the report of his words. The Homeric heroes are exhibited both in action and in speech. Further the contemporary readers of Thucydides were men habituated to a civic life in which public speech played an all-important part. Every adult citizen of a Greek democracy was a member of the assembly which debated and decided great issues. The law-courts, the festivals, the drama, the market-place itself, ministered to the Greek love of animated description. To a Greek of that age a written history of political events would have seemed strangely insipid if speech "in the first person" had been absent from it, especially if it did not offer some mirror of those debates which were inseparably associated with the central interests and the decisive moments of political life. In making historical persons say what they might have said, Thucydides confined that oratorical license to the purpose which is its best justification; with him it is strictly dramatic, an aid to the complete presentment of action, by the vivid expression of ideas and arguments which were really current at the time. Among later historians who continued the practice, Polybius, Sallust, and Tacitus most resemble Thucydides in this particular; while in the Byzantine historians, as in some moderns who followed classical precedent, the speeches were usually mere occasions for rhetorical display. Botta's *History of Italy* from 1780 to 1814 affords one of the latest examples of the practice, which was peculiarly suited to the Italian genius.

The eight books.

The present division of the History into eight books is one which might well have proceeded from the author himself, as being a natural and convenient disposition of the contents. The first book, after a general introduction, sets forth the causes of the Peloponnesian War. The first nine years of the war are contained in the second, third, and fourth books,—three years in each. The fifth book contains the tenth year, followed by the interval of the "insecure peace." The Sicilian expedition fills the sixth and seventh books. The eighth book opens that last chapter of the struggle which is known as the "Decelean" or "Ionian" War, and breaks off abruptly—in the middle of a sentence, indeed—in the year 411. The words in which Grote bids farewell, at that point, to Thucydides well express what every careful student must feel. "To pass from Thucydides to the *Hellenica* of Xenophon is a descent truly mournful; and yet, when we look at Grecian history as a whole, we have great reason to rejoice that even so inferior a work as the latter has reached us. The historical purposes and conceptions of Thucydides, as set forth by himself in his preface, are exalted and philosophical to a degree altogether wonderful, when we consider that he had no pre-existing models before him from which to derive them. And the eight books of his work (in spite of the unfinished condition of the last) are not unworthy of these large promises, either in spirit or in execution."

Origin of that division.

The principal reason against believing that the division into eight books was made by Thucydides himself is the fact that a different division, into thirteen books, was also current in antiquity, as appears from Marcellinus (§ 58). It is very improbable—indeed hardly conceivable—that this should have been the case if the eight-book division had come down from the hand of the author. We may infer, then, that the division of the work into eight books was introduced at Alexandria,—perhaps in the 3d or 2d century B.C. That division was already familiar to the grammarians of the Augustan age. Dionysius of Halicarnassus, who recognizes it, has also another mode of indicating portions of the work, viz., by *stichometria*, or the number of lines which they contained. Thus, in the MS. which he used, the first 87 chapters of book i. contained about 2000 lines (equivalent to about 1700 lines in Bekker's stereotyped 8vo text).

Order of composition.

Ullrich has maintained with much acuteness that Thucydides composed the first three books and about half of book iv. in the years 421–413, and the rest of the work after 404. His general ground is the existence in i.–iv. of passages which seem to imply ignorance of later events. Classen has fully examined the evidence, and, as a result, has arrived at the following conclusion. It is possible that a first rough draft of the History, down to 413, may have been sketched by Thucydides before 405. But the whole History, from the first book onwards, was worked up into its present form only after 404. This view is confirmed by some passages, found even in the earliest books, which imply that the writer already knew the latest incidents, or the final issue, of the war. We have seen that, after 404, Thucydides may have enjoyed some six or seven years of leisure. Several peculiarities of expression or statement in book viii. suggest that it had not yet received the author's final revision at the time when death broke off the work. The absence of speeches from the eighth book has also been remarked. But it should be observed that much of the eighth book is occupied with negotiations, either clandestine or indecisive, or both. Its narrative hardly presents any moment which required such dramatic emphasis as the speeches usually impart. The mere misrepresentations by which Alcibiades and Chalcideus prevailed on the Chians to revolt certainly did not claim such treatment.

Mode of reckoning time.

The division of the war by summers and winters (κατὰ θέρος καὶ χειμῶνα)—the end of the winter being considered as the end of the year—is perhaps the only one which Thucydides himself used, for there is no indication that he made any division of the History into books. His "summer" includes spring and autumn, and extends, generally speaking, from March or the beginning of April to the end of October. His "winter"—November to February inclusive—means practically the period during which military operations, by land and sea, are wholly or partly suspended. When he speaks of "summer" and "winter" as answering respectively to "half" the year (v. 20. 3), the phrase is not to be pressed: it means merely that he divides his year into these two parts. The mode of reckoning is essentially a rough one, and is not to be viewed as if the commencement of summer or of winter could be precisely fixed to constant dates. For chronology, besides the festivals, he uses the Athenian list of archons, the Spartan list of ephors, and the Argive list of priestesses of Hera.

There is no reference to the History of Thucydides in the extant Greek writers of the 4th century B.C.; but Lucian has preserved a tradition of the enthusiasm with which it was studied by Demosthenes. The great orator is said to have copied it out eight times, or even to have learned it by heart. It is at least beyond doubt that the study of Thucydides contributed a very powerful influence to the style of Demosthenes, though that influence rather passed into the spirit of his oratory than showed itself in any marked resemblances of form. The Alexandrian critics acknowledged Thucydides as a great master of Attic. Sallust, Cornelius Nepos, Cicero, and Quintilian are among the Roman writers whose admiration for him can be traced in their work, or has been expressly recorded. The most elaborate ancient criticism on the diction and composition of Thucydides is contained in three essays by Dionysius of Halicarnassus.

MSS., etc.

Among the best MSS. of Thucydides, the Codex Vaticanus 126 (11th cent.) represents a recension made in the Alexandrian or Roman age. In the first six books the number of passages in which the Vaticanus alone has preserved a true reading is comparatively small; in book vii. it is somewhat larger: in book viii. it is so large that here the Vaticanus, as compared with the other MSS., acquires the character of a revised text. Other important MSS. are the Palatinus 252 (11th cent.); the Casselanus (1252 A.D.); the Augustanus Monacensis 430 (1301 A.D.). A collation, in books i. ii., of two Cambridge MSS. of the 15th century (NN. 3. 18, KK. 5. 19) has been published by Shilleto. Several Parisian MSS. (H. C. A. F.), and a Venetian MS. (V.) collated by Arnold, also deserve mention. The Aldine edition was published in 1502. It was formerly supposed that there had been two Juntine editions. Shilleto, in the "Notice" prefixed to book i., first pointed out that the only Juntine edition was that of 1526, and that the belief in an earlier Juntine, of 1506, arose merely from the accidental omission of the word *vicesimo* in the Latin version of the imprint.

Of recent editions, the most generally useful is Classen's, in the Weidmann series (Berlin, 1862–78); each book can be obtained separately. Arnold's edition (1848–51) contains much that is still valuable. For books i. and ii. Shilleto's edition (1872–76) furnishes a commentary which, though not full, deals admirably with many difficult points. Among other important editions, it is enough to name those of Duker, Bekker, Goeller, Poppo, and Krüger. Bétant's lexicon to Thucydides (2 vols., Geneva, 1843) is well executed. Jowett's translation (Oxford, 1883) is supplemented by a volume of notes. Dale's version (Bohn) also deserves mention for its fidelity, as Crawley's (London, 1876) for its vigor. *Hellenica* (London, 1880) contains an essay on "The Speeches of Thucydides," pp. 266-323, which has been translated into German. The best clue to Thucydidean bibliography is in Engelmann's *Scriptores Græci*, pp. 748 *sq.*, 8th ed., 1880. (R. C. J.)

THUGS. That the Sanskrit root *sthag* (Pali, *ṭhak*), "to cover," "to conceal," was mainly applied to fraudulent concealment, appears from the noun *sthaga*, "a cheat," which has retained this signification in the modern vernaculars, in all of which it has assumed the form *ṭhag* (commonly written *thug*), with a specific meaning. The Thugs were a well-organized confederacy of professional assassins, who in gangs of from 10 to 200 travelled in various guises through India, wormed themselves into the confidence of wayfarers of the wealthier class, and, when a favorable opportunity occurred, strangled them by throwing a handkerchief or noose round their necks, and then plundered and buried them. All this was done according to certain ancient and rigidly prescribed forms and after the performance of special religious rites, in which the consecration of the pick-axe and the sacrifice of sugar formed a prominent part. From their using the noose as an instrument of murder they were also frequently called *Phânsigârs*, or "noose-operators." Though they themselves trace their origin to seven Mohammedan tribes, Hindus appear to have been associated with them at an early period; at any rate, their religious creed and practices as staunch worshippers of Devî (Kâlî, Durgâ), the Hindu goddess of destruction, had certainly no flavor of Islam in them. Assassination for gain was with them a religious duty, and was considered a holy and honorable profession. They had, in fact, no idea of doing wrong, and their moral feelings did not come into play. The will of the goddess by whose command and in whose honor they followed their calling was revealed to them through a very complicated system of omens. In obedience to these they often travelled hundreds of miles in company with, or in the wake of, their intended victims before a safe opportunity presented itself for executing their design; and, when the deed was done, rites were performed in honor of that tutelary deity, and a goodly portion of the spoil was set apart for her. The fraternity possessed also a jargon of their own (Ramâsî), as well as certain signs by which its members recognized each other in the remotest parts of India. Even those who from age or infirmities could no longer take an active part in the operations continued to aid the cause as watchers, spies, or dressers of food. It was owing to their thorough organization, the secrecy and security with which they went to work, but chiefly to the religious garb in which they shrouded their murders, that they could, unmolested by Hindu or Mohammedan rulers, recognized as a regular profession and paying taxes as such, continue for centuries to practice their craft. Both the fractions into which they were divided by the Nerbudda river laid claim to antiquity: while the northern, however, did not trace their origin farther back than the period of the early Mohammedan kings of Delhi, the southern fraction not only claimed an earlier and purer descent, but adhered also with greater strictness to the rules of their profession.

The earliest authenticated mention of the Thugs is found in the following passage of Zíáu-d dín Barní's *History of Firoz Sháh* (written about 1356): "In the reign of that sultan," that is, about 1290, "some Thugs were taken in Delhi, and a man belonging to that fraternity was the means of about a thousand being captured. But not one of these did the sultan have killed. He gave orders for them to be put into boats and to be conveyed into the lower country, to the neighborhood of Lakhnautí, where they were to be set free. The Thugs would thus have to dwell about Lakhnautí, and would not trouble the neighborhood of Delhi any more" (Sir H. M. Elliot's *History of India*, vol. iii. p. 141). The first European travellers who speak of them without mentioning their name are Thevenot (1665) and Fryer (1673). Though instances of Thuggee had been known to the English rulers in India for many years, and sporadic efforts had been made by them towards the extinction of the gangs, it was not till Lord W. Bentinck (1828–35) took vigorous steps in this matter that the system was gradually unmasked, and finally all but stamped out. His chief agent, Captain (afterwards Sir William) Sleeman, with several competent assistants, and the co-operation of a number of native states, succeeded in completely grappling with the evil, so that up to October, 1835, no fewer than 1562 Thugs had been committed, of which number 382 were hanged and 986 transported or imprisoned for life. It is true that, according to the *Thuggee and Dacoity Report for* 1879, the number of registered Punjabi and Hindustani Thugs then still amounted to 344. But all of these had already been registered as such before 1852. It may, therefore, fairly be assumed that none are alive now, and that the whole fraternity may be considered as extinct.

Full particulars concerning the system of Thuggee are given by Dr. Sherwood, "On the Murderers called Phánsigárs," and J. Shakespear, "Observations regarding Bradheks and Thegs" (both treatises in vol. xiii., 1820, of the *Asiatic Researches*); [W. N. Sleeman], *Ramaseeana, or a Vocabulary of the Language used by the Thugs, with an Introduction and Appendix*, Calcutta, 1836; the *Edinburgh Review* for Jan., 1837; [E. Thornton], *Illustrations of the History and Practices of the Thugs*, London, 1837; Meadows Taylor, *Confessions of a Thug*, London, 1839; Major Sleeman, *Report on the Depredations committed by the Thug Gangs*, Calcutta, 1840; J. Hutton, *Popular Account of the Thugs and Dacoits*, London, 1857; Yule and Burnell, *Glossary of Anglo-Indian Colloquial Words and Phrases*, London, 1886, p. 696 *sq.* (R. R.)

THUGUT, FRANZ MARIA VON (1734–1818), foreign minister of Austria, was born of humble parentage at Linz in 1734, placed in the Government school of Oriental studies in 1752, and sent to Constantinople as an interpreter in 1757. At Constantinople he rose from post to post in the embassy, until in 1771 he became internuncius or ambassador. In 1776, after the war between Russia and Turkey, he obtained from the latter power the cession of the province of Bukowina to Austria. After thus crowning his long service in the East and gaining the confidence of Maria Theresa, he was sent by her without the knowledge of her son, the emperor Joseph, to Berlin, to avert by a peaceful settlement with Frederick the Great the threatened Bavarian war. In 1790 he was employed in the negotiations of Sistova, and his next mission was to Paris, where he entered into close relations with Mirabeau as the friend of Marie Antoinette. On the invasion of France by the allied armies in 1792, Thugut was sent to the scene of operations. It is well known that Kaunitz, the veteran minister of Austria, condemned the terms of the alliance with Prussia, as securing to Prussia the annexation of a great part of Poland, while only holding out to Austria an uncertain prospect of acquiring its equivalent in Bavaria. Thugut, a politician of the same school, viewed the new alliance with even greater hatred. After the failure of the campaign of 1792 he formed the deliberate opinion that persons around the duke of Brunswick had been bribed by the French, and that the retreat had been ordered in consequence. A few months later the anticipations of Kaunitz were realized. Prussia seized western Poland, while Austria remained as far as ever from gaining Bavaria. The emperor Francis now dismissed the ministers responsible for the Prussian alliance, and called Thugut to power. From this critical moment the alliance was doomed, and the allied commanders thwarted rather than assisted one another's operations on the eastern frontier of France. On the other hand, Thugut drew nearer to Russia, and negotiated at St. Petersburg for the seizure of Venice by Austria. With England he desired to stand on a good footing; but, while Pitt's object was the overthrow of the revolutionary Government, Thugut's was simply the acquisition of territory for Austria. This discrepancy of aim led to results exasperating to the English ministry, such as the fall of Toulon, to which Thugut neglected to send the troops which he had promised. The evacuation of Belgium in 1794, usually attributed to Thugut's treachery, was, however, due to the incapacity or intrigues of others. In 1795, after the withdrawal of Prussia from the coalition, Thugut obtained financial help from England, gained from Russia a large share of Poland in the last partition, and prepared to carry on the war against France with the utmost energy. The campaign of the archduke Charles in 1796 drove the French from the east of the Rhine, and Bonaparte, who had conquered northern Italy up to Mantua, narrowly escaped destruction before this fortress. But for the genius of the French commander and the wretched character of the Austrian generals and officers, the immense efforts made by Thugut at this time would have turned the tide of the war. Defeat after defeat seemed to make no impression upon his "world-desolating obstinancy;" and, even when Bonaparte had advanced to within eighty miles of Vienna, it is stated that the empress had to throw herself at her husband's feet when in conference with his minister, in order to overcome the resistance of the latter to an armistice. The subsequent peace of Campo Formio was hotly condemned by Thugut, who tendered his resignation. Then followed the congress of Rastadt and the murder of the French envoys, long attributed, but without any real ground, to Thugut himself. War was renewed; the French were driven out of Italy by Austrian armies assisted by Suwaroff; and it was determined that the allies should conquer Switzerland, and so invade France where the frontier is most open. Thugut, now at the height of his power, and far more anxious to recover Belgium than to overthrow the republic, took the fatal step of withdrawing a great part of the Austrian forces from Switzerland at the very moment when the Russians were entering it. The result was the destruction of the Russians by Masséna and the total failure of the campaign, followed by the secession of Russia from the coalition. Still full of designs for annexation in Italy, Thugut continued the war with the help of England. On the very day when he renewed his engagements with England the news arrived of the battle of Marengo, which at one blow made an end of all that Austria had won in Italy in the preceding year. Nothing daunted, Thugut continued, during the armistice which followed, his preparation for the struggle with Moreau in the valley of the Danube; and, if he could have inspired his master with his own resolute spirit, the result of the war might have been different. But, while Thugut was actually receiving the British subsidies, the emperor, without the knowledge of his minister, surrendered the fortresses of Ulm and Ingolstadt to Moreau, in return for an extension of the armistice. Thugut's passionate indignation on learning of this miserable act is impressively described in Lord Minto's despatches from Vienna. He withdrew from office; but Lord Minto's protests compelled the emperor again to place in his hands the direction of affairs, which he held until the battle of Hohenlinden made all further resistance impossible. He was then, in deference to French influence, banished from Vienna, and never resumed office. In his retirement he was occasionally consulted, as after the battle of Wagram in 1809, when he recommended the emperor to make peace at any cost, stating that the existence of the Austrian monarchy was at stake and that the dissolution of Napoleon's empire was not far off. After the overthrow of Napoleon, he returned to the capital, where he died May 29, 1818. Thugut possessed many of the qualities of a great man,—indomitable courage, calmness in danger, devotion to public interests, enormous industry; but all this was spoilt by the persistent disregard of obligations towards allies in the greedy pursuit of Austria's own aggrandizement, and by the intriguing spirit inseparable from this policy. The materials for forming a fair estimate of Thugut's conduct of affairs from 1793 to 1801 have but recently been given to the world. Of his private life next to nothing is known.

THULE was the name given by Greek and Roman geographers to a land situated to the north of Britain, which they believed to be the most northerly portion of Europe, or indeed of the known world. The first writer who mentioned the name was Pytheas of Massilia, whose statements concerning it have been already given under the heading PYTHEAS. But it is impossible for us to determine with certainty what those statements, which have only been transmitted to us at second or third hand, really were, and still more so what was their real signification. It is almost certain that Pytheas did not himself profess to have visited Thule, but had only vaguely heard of its existence, as a land of unknown extent, situated, according to the information he had received, six days' voyage to the north of Britain. This account was adopted by Eratosthenes (though rejected by Polybius and Strabo), and accordingly this unknown land became a cardinal point in the systems of many ancient geographers, as the northern limit of the known world. Nothing more was learnt concerning it until the Romans under Agricola (about 84 A.D.) accomplished the circumnavigation of the northern point of Britain, and not only visited, but according to Tacitus, subdued, the Orcades or Orkney Islands. On this occasion, the historian tells us, they caught sight also of Thule,[1] which in this instance could only mean the group of the Shetland Islands. No further account of this mysterious land is found in any ancient author, except vague statements, derived from Pytheas, but mostly in an inaccurate and distorted form, concerning its position and the astronomical phenomena resulting from this cause. It is probable that what Pytheas really reported was that at the summer solstice the days were twenty-four hours in length, and conversely at the winter solstice the nights were of equal duration, a statement which would indicate the notion of its position in about 66° N. lat., or under what we now call the Arctic Circle. The skill of Pytheas as an astronomer would have been quite sufficient to lead him to the conclusion that this would be the case at some point in proceeding northwards, and the rapid changes in this respect that would be reported to him by any navigators that had really followed the shores of Britain to any considerable extent in that direction would confirm him in the correctness of his views. He had, too, a very exaggerated notion of the extent of Britain (see PYTHEAS), and hence he would be led to place an island which was six days' voyage to the north of it much nearer to the Arctic Circle than its true position.

The statement of Pytheas on this point appears to have obtained almost universal belief until the time of Marinus of Tyre and his successor Ptolemy, who were led—apparently from their knowledge that the group of islands to which the name of Thule had been applied by the Romans was really not very far distant from the Orcades—to bring down its position considerably more to the south, so that Ptolemy places the island of Thule, which he still regards as the most northerly point of Europe, in only 63° N. lat. Unfortunately this more reasonable view has been discarded by many modern writers, who have gone back to the statements of Pytheas concerning the length of the day, and have in consequence insisted upon placing Thule within the Arctic Circle, and have thus been led to identify it with Iceland. The improbability of such an hypothesis, when we consider the state of ancient navigation, is in itself a sufficient refutation, and there appears no reasonable doubt that the Thule of Pytheas, like that of the Romans and of Ptolemy, was merely an exaggerated and somewhat erroneous conception of the large group of the Shetland Islands, of which the principal, called Mainland, is in fact so predominant that the whole may well have been considered as one large island rather than a scattered group like the Orkneys. If we might trust to the accuracy of Strabo's quotation (ii. 5, p. 114), that Pytheas called Thule "the most northerly of the British Islands," this would be decisive on the point; but unfortunately the *verbal* accuracy of such references by ancient writers can seldom be relied on, and Strabo had evidently never seen Pytheas's original work.

---

[1] "Dispecta est et Thule," Tac., *Agric.*, c. 10.

It appears, however, to be certain that Iceland was really visited by some Irish monks long before its discovery by the Northmen, and is described under the name of Thule by a writer named Dicuil, himself an Irish monk, who wrote in the first half of the 9th century, in such a manner as to leave no doubt that his statements really refer to that extensive but remote island. See Letronne, *Recherches sur Dicuil*, Paris, 1814.

THÜMMEL, MORITZ AUGUST VON (1738–1817), German writer in prose and verse, one of the imitators of Wieland (see vol. x. p. 483), was born May 27, 1738, in the neighborhood of Leipsic, was educated at Rossleben and the university of Leipsic, and from 1761 till 1783 held various offices in the ducal court of Saxe-Coburg. He died at Coburg on October 26, 1817. He wrote a comic prose epic, *Wilhelmine, oder der vermählte Pedant* (1764); *Die Inoculation der Liebe* (1771), a tale in verse; *Reise in die mittäglichen Provinzen von Frankreich* (1791–1805), a romance in 10 vols.; and *Der heilige Kilian, oder das Liebespaar* (1818). An edition of his works was published at Leipsic in 8 vols. in 1854–55.

THUNBERG, CARL PETER (1743–1828), an eminent traveller, and one of the most distinguished botanists of the school of Linnæus, was born in 1743. He became a pupil of Linnæus at the university of Upsala, where he graduated in medicine in 1770. Obtaining a travelling scholarship, he visited Holland, whence he embarked on a voyage of exploration to Java, in quest of vegetable treasures. He sailed as far as the Cape of Good Hope in 1771, and three years afterwards went to Japan, remaining five years, engaged in making collections of plants, and in observing the habits, manners, and language of the people. On his return in 1779 he visited England, and made the acquaintance of Sir Joseph Banks. In 1777 he was made demonstrator of botany at Upsala, and he succeeded Linnæus as professor of botany in 1784. Thunberg published in 1784 his *Flora Japonica*; in 1788 he began to publish his travels. He completed his *Prodromus Plantarum* in 1800, in 1805 his *Icones Plantarum*, and in 1813 his *Flora Capensis*. Thunberg published numerous memoirs in the *Transactions* of many Swedish and foreign scientific societies, of sixty-six of which he was an honorary member. He died in 1828.

THUNDERSTORM. All the more ordinary phenomena of thunderstorms had, about 1750, been conclusively traced to electrical charges and discharges (ELECTRICITY, vol. viii. p. 7), so that they could easily be reproduced on a small scale in the laboratory. To the article cited we therefore refer for their explanation. Some of the laws of relative frequency of thunderstorms, in different places at the same season or in the same place at different seasons, will be found in METEOROLOGY (vol. xvi. p. 133 *sq.*). A discussion of the cause of thunder, and of the circumstances which give rise to a crash, a roll, or a peal of thunder is given under ACOUSTICS (vol. i. p. 100). In what follows, therefore, the rarer phenomena of thunderstorms, and the possible sources of the atmospheric electricity, will be the chief points treated.

There can be little doubt that atmospheric electricity, at least in the great developments which characterize a thunderstorm, is due in some way to water. Before a great thunderstorm the lower air is usually at an abnormally high temperature, and fully saturated with water vapor, so that it is in a thoroughly unstable condition. Immense cloud masses, often miles in vertical thickness, which produce almost midnight darkness by day in the region of the storm, and which appear, when seen from a distance, as if boiling upwards, are always a notable feature of great thunderstorms. These are usually accompanied by torrents of rain, or by violent hail-showers. And it is commonly observed that each flash of lightning is followed, after a brief interval, by a sudden but temporary increase in the rate of rainfall. At what stage of its transformations the electrification is developed by water-substance is, as yet, only guessed at,—though it seems most reasonable to conclude that it is anterior to the formation of cloud, *i.e.*, to the condensation of vapor. And, though the idea was at one time very generally held and still has many upholders, it seems unlikely to be the direct result of evaporation. For, were it due directly either to evaporation or to condensation, it is almost impossible to doubt that proof would long since have been furnished by careful experiment, even if made on a scale so limited as that afforded by our laboratories. No trace of electrical effect has been found to attend the precipitation of moisture; and the electrical effects, sometimes considerable, which have been found associated with evaporation have always been accompanied by relatively violent physical and mechanical actions which are not observed in conjunction with atmospheric electricity. It has been suggested by some authorities that the electricity of a thunderstorm is developed during the formation of hail, by others that it is due to the molecular actions which accompany the diminution of total surface when two or more drops of water coalesce into a single one. It has been ascribed to the friction of moist against dry air, and to the dust-particles which appear to be necessary for the condensation of vapor. Again, it has been suggested that it may be a mere phenomenon of contact electricity, due to the impact of uncondensed vapor particles on particles of air. It is almost unnecessary to observe that, whatever hypothesis we adopt, some explanation must be given of two important points: (1) What becomes of the electricity equal and opposite to that in each drop, which must be produced simultaneously with it? (2) By what means is the attraction between the drops and the recipient of the opposite charge of electricity overcome so that the drops may be enabled to part with their charge? It is to be presumed that gravity satisfies the second of these questions. As to the first, it seems to necessitate the presence of something besides water, in order that the electric separation may be commenced, and thus appears to be fatal to the capillary theory indicated above. Whatever be the true source of the charge, it is easy to see, by known properties of electricity, that even an exceedingly small charge on each vapor particle would lead to a very high potential as soon as a visible drop is formed, and that as a drop increases in size its potential is proportional to its surface. That drops of rain are often individually electrified to a very high potential is proved by the frequent occurrence of "luminous rain," when the ground is feebly lit up by the multitude of tiny sparks given out by the drops as they come near it. The flakes of falling snow, also, are often strongly electrified, so that smart sparks have been drawn from an umbrella on which the snow was falling. But the law of electric repulsion shows us at once that, as soon as the drops in a cloud are sufficiently electrified, at least the greater part of their charge must pass to the boundary of the cloud. When this occurs, the nature of the further behavior of the charge presents no difficulty. The reason for our singularly complete ignorance of the source of atmospheric electricity seems to lie in the fact that it can only be discovered by means of experiments made on a scale very much larger than is attainable with the ordinary resources of a laboratory. The difficulties will probably be easily overcome by the first nation which will go to the expense of providing the necessary means.

Numberless other explanations of the origin of thunderstorms have been suggested; but the more reasonable of these do little more than shift the difficulty, for they begin by assuming (without any hint as to its source) an electrification of the earth as a whole, or of the lower (sometimes the upper) layers of the atmosphere. Induction, convexion, etc., are then supposed to effect the rest. Another and much less reasonable class of explanations depends upon magneto-electricity. Some of these introduce the so-called "unipolar" induction supposed to be due to the rotation of the earth, which behaves like a gigantic magnet. Of this nature is the suggestion of Edlund, which was recently crowned by the Academy of Sciences of Paris. That rapid variations in the earth's magnetic elements, such as often occur on a large scale, as in a "magnetic storm," have at least a share in the production of the aurora is a perfectly reasonable and even plausible hypothesis, long ago brought forward by Balfour Stewart. But we have yet to seek the source of these variations.

The brightness of a flash of lightning is usually much underrated. It is true that it rarely gives even at night an illumination greater than that due to moonlight. But it must be remembered that Swan has proved that the impression of a flash on the eye depends upon the duration, being nearly proportional to it, and steadily increasing for about a tenth of a second. Now the duration of a lightning-flash is (roughly speaking) only about one millionth of a second. This is proved by the fact that the most rapidly rotating bodies appear to be absolutely steady when illuminated by it. Hence, if it could be made to last for a tenth of a second, it would give near objects an illumination one hundred thousand times more brilliant than that of moonlight. It must be remembered that the flash is not a mere line, but a column, of intensely heated air, driven outwards from the track of the discharge at a rate initially far greater than that of sound.

What is called "summer lightning" or "wild-fire" is sometimes a rather puzzling phenomenon. In the majority of cases it is merely the effect of a distant thunderstorm. It is also often due to a thunderstorm in the higher strata of the atmosphere overhead,—the reason why we hear no thunder being not so much the distance from the spectator as the fact that sounds generated in rarer air lose rapidly in intensity as they are propagated into denser air. But, besides these more common forms of the phenomenon, there is certainly a form of sheet lightning which occurs, without either sound or cloud, often close to the spectator. The cause of this is not at all obvious.

But the most mysterious phenomenon is what goes by the name of "globe lightning" or "fire-ball," a phenomenon lasting sometimes for several seconds, and therefore of a totally different character from that of any other form of lightning. The fire-ball is almost incomparably less brilliant than forked lightning, because, though it lasts long enough to give the full impression of its brightness, it is rarely brighter than iron in the state which we call "red-hot." It is always spherical, often more than a foot in diameter, and appears to fall from a thunder-cloud by its own gravity, sometimes rebounding after striking the ground. It usually bursts with a bright flash and a loud explosion, occasionally discharging flashes of lightning. No experimenter has yet succeeded in producing artificially anything resembling these natural and intensely charged Leyden jars.

The term "thunderbolt," which is nowadays rarely used except by poets (and by the penny-a-liners), preserves the old notion that something solid and intensely hot passed along the track of a lightning flash and buried itself in the ground. Two distinct classes of phenomena probably gave rise to this notion. When lightning strikes the ground it often bores a hole of considerable depth, which is found to be lined in its interior with vitrified sand. This presents no difficulty. But Aerolites (*q.v.*) are often found, in the holes which they have made, still intensely hot, in consequence of their rapid passage through the air. A hasty generalization seems to have connected these two entirely independent phenomena, and thus given rise to the notion of the thunderbolt. The ancient notion that a lightning flash could occur in a clear sky is probably to be accounted for by the occasional appearance of these ultramundane visitors.

The sulphurous smell of lightning, which is vividly described in the *Odyssey*, is now known to be due to the formation of Ozone (*q.v.*).

For the precautions necessary to prevent danger from a thunderstorm, see Lightning Conductor.

A whole volume of Arago's collected works is devoted to thunderstorms, and many important observations are to be found in the writings of M. D'Abbadie and other scientific travellers. (P. G. T.)

THÚN-KHWA, or Thonegwa, a district in the Pegu division of Burmah, lying between 17° 37′ and 19° 28′ N. lat., and between 95° 53′ and 96° 53′ E. long., with an area of 5413 square miles. It is bounded on the N. by Henzada, E. by Rangoon, S. by the Bay of Bengal, and W. by Bassein district. The whole district is a large deltaic plain, divided by the numerous channels of the Irrawaddy into saucer-shaped islands, with deep depressions in the centre. The Irrawaddy traverses Thún-khwa from north to south, throwing off numerous branches until it falls into the Bay of Bengal. Geologically, Thún-khwa is composed of "older alluvial clay," differing from that of the Gangetic basin in being less rich in lime.

The population of Thún-khwa in 1881 was returned at 284,063 (males 150,131, females 133,932); Hindus numbered 723, Mohammedans 1650, Christians 6894, and Buddhists 274,237. The largest towns in the district are Yandoon and Pantanaw, with populations (1881) of 12,673 and 6174 respectively. The land is much less fertile than that of the neighboring districts. In 1885–86 the area under cultivation was 349,259 acres, and the cultivable area 1,262,374 acres. The principal crops are rice, fruits, vegetables, and sugar-cane. The total revenue realized in the year 1885–86 amounted to £194.737 [$946,421.82], of which the land contributed £66,590 [$323,627.40]. Thún-khwa was constituted a district in 1875, and its history previous to that date is identical with that of Henzada, to which administrative division it originally belonged. During the first Burmese war no resistance was offered to the British in the district as it at present exists except at the town of Donabyu. At the time of the second war Donabyu was undefended, but, after the occupation of Prome, Myat Htún, an ex-thúgyi of a small circle, succeeded in collecting a body of men, and defied the British. Early in January, 1853, the enemy were driven out of Donabyu, but on penetrating into the interior the British were forced to retire. In a subsequent engagement the British were driven back; but the enemy were eventually dispersed and their works captured.

THURGAU, or Thurgovia, a canton of Switzerland (ranking as seventeenth in the Confederation), takes its name from the river Thur. It is bounded on the N. by the Rhine, on the E. by the Lake of Constance (the cantonal frontier being so drawn as to leave the town of Constance to Baden), on the S. by a line running from Arbon on the lake west and southwest to Hörnli, and on the W. by a line drawn from Hörnli passing east of Winterthur and west of Frauenfeld to the Rhine, a little west of Diessenhofen and opposite Schaffhausen. It is thus shaped like a triangle, of which the Hörnli (3274 feet, the highest point in the canton) is the apex, and comprises the middle basin of the Thur. Its total area is 381.4 square miles, of which 322.6 (or 84.6 per cent.) is reckoned as "productive land," 69.8 being covered by forests, and 6.9 by vineyards. Of the "unproductive" portion no less than 50.5 square miles consists of the cantonal share of the Lake of Constance. According to the census of 1880, the population amounted to 99,552 (females being in a majority of 1000), an increase of 6252 on the census of 1870; of these, 99,026 are German-speaking. In religion the inhabitants are divided, there being 71,821 Protestants to 27,123 Roman Catholics; the canton till 1815 was in the diocese of Constance, and since 1828 has been in the reconstructed diocese of Basel, though for some time after 1873 the Government would not recognize the authority of Bishop Lachat, in consequence of his support of the dogma of infallibility at the Vatican council. The capital is Frauenfeld (5811 inhabitants), and Romanshorn (population 3647) is an important railway centre on the lake. The canton has many small villages, and the population is chiefly employed in agricultural pursuits, though cotton-spinning is rapidly increasing. The orchards are so splendid that Thurgau has been called "the garden of Helvetia." A network of well-made roads traverses it in every direction.

The Thurgau originally took in all the country, roughly speaking, between the Reuss, the Lake of Lucerne, the Rhine, and the Lake of Constance; but many smaller districts (Zürichgau, Toggenburg, Appenzell, St. Gall) were gradually carved out of it, and the county was reduced to about the size of the present canton when in 1264 it passed by the gift of the last count of Kyburg to his nephew Rudolph of Hapsburg, chosen emperor in 1273. In 1415, the count, Duke Frederick of Austria (a Hapsburg), was put under the ban of the empire by the emperor Sigismund for having aided Pope John XXIII. to escape from Constance, and the county was overrun, Sigismund in 1417 mortgaging to the city of Constance the appellate jurisdiction in all civil and criminal matters ("landgericht" and "blutbann") arising within the county, which he had declared to be forfeited in consequence of Frederick's conduct. In 1460, some of the Confederates, now becoming very eager for conquests, overran and seized the county. Winterthur was saved, but in 1461 Frederick's son, Duke Sigismund, had perforce to cede the county to the Confederates. Henceforth it was ruled as a "subject district" by seven members of the League,—Bern, occupied in the west, not being admitted to a share in the government till 1712, after one of the wars of religion. It was only in 1499 that the Confederation (then consisting of ten members) obtained from Constance her supreme jurisdiction, through the mediation of the duke of Milan, but there were still forty-two minor jurisdictions belonging to various lords, spiritual and temporal, which went on till 1798 and greatly limited the power of the Confederates. Thurgau had hoped, but in vain, to be admitted in 1499 a full member of the Confederation.

At the time of the Reformation many of the inhabitants became Protestants, and bitter quarrels ensued between the Protestant and Catholic (the latter having a large majority) members of the Confederation who had rights over Thurgau, with regard to the toleration of the new doctrines in the "subject districts" such as Thurgau. By the first peace of Kappel (1529) the majority in each "commune" was to settle the religion of that "commune," but by the second (1531, after Zwingli's death) both religions were to be allowed side by side in each "commune." Thurgau thus became a "canton of parity," as it is to this day. Its rulers, however, continued to watch each other very closely, and Kilian Kesselring, one of the chief military commanders in Thurgau, was in 1633, on suspicion of having connived at the advance of the Swedes through Thurgau on Constance, seized by the Catholic cantons and severely punished. In 1798, Thurgau became free, and was one of the nineteen cantons of the Helvetic republic, being formally received (like the other "subject lands") as a full member of the Swiss Confederation in 1803 by the Act of Mediation. It was one of the very first cantons to revise, in 1830, after the July revolution in Paris, its constitution in a very liberal sense, and in 1831 proposed a revision of the federal pact of 1815. This failed, but the new federal constitutions of 1848 (of which one of the two drafters was Kern of Thurgau) and 1874 were approved by very large majorities. In 1849 the cantonal constitution was revised and the veto introduced, by which the people might reject a bill passed by the cantonal assembly. Finally, in 1869, the existing constitution was drawn up, by which the "initiative" (or right of 2500 electors to compel the cantonal assembly to take any subject into consideration) and the "obligatory *referendum*" (by which all laws passed by the cantonal assembly, and all financial resolutions involving a capital expenditure of 50,000 francs or an annual one of 10,000, must be submitted to a popular vote) were introduced. The cantonal government consists of a legislative assembly (now of ninety-seven members, one to every 250 electors) and an executive council of five members, both elected directly by the people; 5000 electors can at any time call for a popular vote on the question of the dismissal of either one or the other. Further, to show the very democratic character of the constitution, it may be added that members of both houses of the federal assembly are in Thurgau elected direct by the people. The "communes" in Thurgau are of no less than eleven or twelve varieties. The division of the lands, etc., of the old "burgher communes" between them and the new communes, consisting of all residents (with whom political power rests), was carried out (1872) in all of the 214 communes; but there are still thirty-eight guilds or corporations with special rights over certain forests, etc.

The best history of the canton is that by J. A. Pupikofer, of which a second and very much enlarged edition is now (1887) being published.

THURII, or Thurium, a city of Magna Græcia on the Gulf of Tarentum, near the site of the older Sybaris (*q.v.*), but farther inland. It owed its origin to an attempt made in 452 B.C. by Sybarite exiles and their descendants to repeople their old home. The new settlement was crushed by Crotona, but the Athenians lent aid to the fugitives, and in 446, or rather in 443, Pericles sent out to Thurii a mixed body of colonists from various parts of Greece, among whom were Herodotus and the orator Lysias. The pretensions of the Sybarite colonists led to dissensions and ultimately to their expulsion; peace was made with Crotona, and also, after a period of war, with Tarentum, and Thurii rose rapidly in power and drew settlers from all parts of Greece, especially from Peloponnesus, so that the tie to Athens was not always acknowledged. The oracle of Delphi determined that the city had no founder but Apollo, and in the Athenian war in Sicily Thurii was at first neutral, though it finally helped the Athenians. Thurii had a democratic constitution and good laws, and, though we hear little of its history till in 390 it received a severe defeat from the rising power of the Lucanians, many beautiful coins testify to the wealth and splendor of its days of prosperity. In the 4th century it continued to decline, and at length called in the help of the Romans against the Lucanians, and then in 282 against Tarentum. Thenceforward its position was dependent, and in the Second Punic War, after several vicissitudes, it was depeopled and plundered by Hannibal (204). In 194, a Roman colony was founded, with Latin rights, known for a time as Copiæ, but afterwards by the old name of Thurii. It continued to be a place of some importance, the situation being favorable and the region fertile, and does not seem to have been wholly abandoned till the Middle Ages. Its site, near Terranova di Sibari, is marked by considerable ruins of the Roman period (*cf.* Lenormant, in *Academy*, xvii. 73, and Barnabei, *ibid.*, xvi. 55 *sq.*).

THURINGIA (Germ. *Thüringen*), a territorial term without modern political significance, designates, strictly speaking, only that district in Upper Saxony that is bounded by the Werra, the Harz Mountains, the Saale, and the Thuringian Forest; but in common parlance it is frequently used as equivalent to the Thuringian states, *i.e.*, the group of small duchies and principalities lying between Prussia, Hesse-Nassau, Bavaria, and the kingdom of Saxony.[1] The name is derived, with great probability, from that of the Hermunduri, a branch of the great Suevic family; and the ancient Thuringians, a heathen tribe first mentioned in the 5th century by Vegetius Renatus, are believed to be the descendants of that Teutonic people. The Thuringians seem at one time to have occupied territories stretching from the Elbe not far from Hamburg to the Danube at Ratisbon; but about 531 their empire was overthrown by the united Franks and Saxons. The north part of their lands fell to the Saxons, and was known for some time as the North Thuringian gau; the district to the south of the

---

[1] The Thuringian states are Saxe-Weimar-Eisenach, Saxe-Coburg-Gotha, Saxe-Meiningen, Saxe-Altenburg, Schwarzburg-Rudolstadt, Schwarzburg-Sondershausen, and the two principalities of Reuss, all of which are separately described. Besides these, the term Thuringia also, of course, includes the various "exclaves" of Prussia, Saxony, Bavaria, and Bohemia which lie embedded among them.

Thuringian Forest was called Franconia after its conquerors; and the name Thuringia was restricted almost to the narrow limits to which it now properly applies. The advance of the Sorbs to the east bank of the Saale about the middle of the 7th century made the limitation still more exact. Thuringia remained under Frankish dominion, and various Frankish counts ruled in the different "gaus" into which it was divided. Christianity, if not introduced, was confirmed in this district by the British Boniface; a bishopric was founded at Erfurt; and under Charlemagne the Thuringian mark was the base of active operations against the heathen Sorbs. In 839 the title of duke of Thuringia (*ducatus Toringuba*) appears; but that of landgrave seems to have superseded it; neither dignity implied sovereignty over the whole district. Otto the Illustrious, duke of Saxony (880), added Thuringia to his duchy, but the union was not permanent. About the beginning of the 12th century Louis the Springer, builder of the Wartburg, rose to eminence among the Thuringian nobles; and about 1130 his son, also Louis, was appointed landgrave by the emperor Lothair I. Thuringia now began to be a united land under one prince; and the landgraves, who acquired the Saxon palatinate on the fall of Henry the Lion of Saxony in 1180, rose to considerable power. The last landgrave of this line was Henry Raspe (1242–1247), brother and successor of Louis the Saint. His death was followed by a devastating war of succession between his niece Sophia, duchess of Brabant, and Henry the Illustrious, margrave of Meissen (1221–1288), whose mother Jutta was a Thuringian princess. Peace was finally established in 1263: Sophia received Hesse, and Henry took the rest of Thuringia, the general history of which thenceforth merged in that of Meissen, and later of Saxony, although it maintained its separate name. Thuringia was included in the administrative circle of upper Saxony (see vol. xxi p. 368, note 1). For its subsequent fate, and the rise of the present Thuringian states, see under SAXONY (vol. xxi. p. 369 *sq.*).

The most striking natural feature of Thuringia is the Thuringian Forest (*Thüringerwald*), a range or system of hills, extending in an irregular line from the neighborhood of Eisenach in the northwest to the Lobensteiner Kulm on the Bavarian frontier on the southeast, and forming the southern boundary of Thuringia, separating it from Franconia. On the southeast it is continued directly by the Frankenwald Mountains to the Fichtelgebirge, which is in immediate connection with the Erzgebirge, while on the northeast it approaches the Harz Mountains, and thus takes its place in the great Sudetic chain of central Germany. The length of the Thuringian chain is 70 miles, and its breadth varies from 8 to 25 miles. It nowhere rises into peaks, and only a few of its rounded summits reach the height of 3000 feet; the successive hills melt into each other in gentle undulations, forming a continuous and easily traced comb, and only the northwest slopes are precipitous, and seamed with winding gorges. This mountain range encloses many charming and romantic valleys and glens; the most prominent feature of its picturesque scenery is formed by the fine forests, chiefly of pines and firs, which clothe most of the hills. The northwest part of the system is the loftier and the more densely wooded, as well as the more beautiful; the highest summits here are the Grosser Beerberg (3225 feet), Schneekopf (3179), and the Inselberg (2957), all in the duchy of Gotha. The southeast part of the Thuringian Forest is the more populous and industrial; the chief summits are the Kieferle (2851 feet) at Steinheid, the Blessberg (2834 feet) near Schalkau, the Wurzelberg (2746 feet) near Oelze, and the Wetzstein (2719) near Lehesten. The crest of the Thuringian Forest, from the Werra to the Saale, is traversed by the Rennsteig or Rainsteig, a broad path of unknown antiquity, though it is believed to be referred to in a letter of Pope Gregory III. dated 738. The name means probably "frontier-path;" and the path marks in fact the boundary between Thuringia and Franconia. It may be also regarded as part of the boundary-line between North and South Germany, for dialect, customs, local names and costume are different on the two sides.

THURINGORUM LEX. See SALIC LAW.

THURLES, an ancient market-town of Ireland, in the county of Tipperary, and the seat of the Catholic archdiocese of Cashel, is pleasantly situated on the Suir, and on the Great Southern and Western Railway, 46 miles east of Limerick, 29 west from Kilkenny and 87 southwest of Dublin. The cathedral of St. Patrick is a beautiful building, erected at a cost of £45,000 [$218,700]. The town is the seat of other important Catholic establishments, including an Ursuline convent, in which is a large boarding-school for young ladies; a Presentation convent; St. Patrick's Catholic college (1829) for ecclesiastical students, where was held in 1850 the synod of Thurles, composed of all the Catholic bishops of Ireland; and an establishment of Christian Brothers, who devote themselves to the instruction of boys on the Lancastrian method. The town has a considerable agricultural and retail trade. The population was 5008 in 1871, and 4850 in 1881.

Originally the town was called Durlas O'Fogarty. In the 10th century it was the scene of the defeat of the Irish by the Danes. A preceptory was founded here by the Knights Templars, who possessed themselves of a castle erected early in the 13th century. A castle was subsequently erected by James Butler, first lord palatine of Tipperary, of which till recently a tower still remained.

THURLOW, EDWARD THURLOW, BARON (1732–1806), was born at Bracon-Ash, in the county of Norfolk, in 1732. His father was a clergyman, and held successively the livings of Little Ashfield in Suffolk and of Stratton St. Mary's in Norfolk. His mother Elizabeth was the daughter of Robert Smith of Ashfield. Thurlow received his early education at home. He was next placed under the care of Mr. Brett at Scarning, where he remained for four years, and was then sent to the grammar school of Canterbury, where he was considered a bold refractory clever boy. In October, 1748, Thurlow entered Caius College, Cambridge, and speedily justified his school reputation. The dean of the college, upon the extent and accuracy of whose classical acquirements grave suspicion rested, had directed him, as a punishment for some act of insurbordination, to translate a chapter of the *Spectator* into Greek. Thurlow executed his task with care, and then gave it for revisal, not to the dean, but to the tutor of the college. When reprimanded for having thus infringed the college rules, Thurlow retorted that he had carried his exercise to one who could inform the dean whether or not he had obeyed his orders. The insult was too grave for rustication, and yet too slight to justify expulsion. Thurlow was therefore permitted to withdraw his name from the college books, and he left Cambridge without a degree (1751). He now took chambers, and began regularly to keep terms in the Inner Temple, which he had joined while still an undergraduate. He was for some time a pupil along with the poet Cowper in the office of Mr. Chapman, an eminent solicitor in Lincoln's Inn. On 22d November, 1754, Thurlow was called to the bar, and subsequently went on the western circuit—at first with little success. But the tide turned. In the case of Luke Robinson *v.* the Earl of Winchelsea (1758) Thurlow came into collision with Sir Fletcher Norton, then the terror of solicitors and the tyrant of the bar, and put down his arrogance with dignity and success. From this time his practice increased rapidly. In December, 1761, he was made a king's counsel, through the influence of the duchess of Queensberry. In January, 1762, he was elected a bencher of the Inner Temple. It now became necessary for him to take his side in politics, and, after repeated oscillations, and with some hesitancy, Thurlow threw himself into the ranks of the Tory party. In May, 1768, he became member for Tamworth. In 1769 the Douglass Peerage case came on for hearing in the House of Lords, and Thurlow, who had drawn the pleadings some years before (*Notes and Queries*, 3d ser., iii. 122), led for the appellant in a speech of great ability and analytic power. In March, 1770, as a recognition of his defence in the previous January of the expulsion of Wilkes, Thurlow was made solicitor-general on the resignation of Dunning, and in the following year (23d January, 1771), after he had enhanced his reputation with the Government by attacking the rights of juries in cases of libel (Rex *v.* Miller, 20 *State Trials*, 870–896) and the liberty of the press (16 *Parly. Hist.*, 1144), was raised to the attorney-generalship. Thurlow's public life was as factious as his youth had been daring. His violent hatred of the American colonists, and his extreme and imprudent assertion that as attorney-general he might set aside by *scire facias* as forfeited every charter in America (debate on the American Prohibitory Bill, 18 *P. H.*, 999); his speech in aggravation of punishment in the case of Horne Tooke (20 *St. Tr.*, 777–783), when he argued that the prisoner ought to be pilloried, because imprisonment was no penalty to a man of sedentary habits and a fine would be paid by seditious subscription; and his consistent opposition to all interference with the slave trade,—are characteristic of the man. In 1778 Thurlow became lord chancellor and Baron Thurlow of Ashfield (June), and took his seat in the House of Lords, where he soon acquired an almost dictatorial power. He resolutely opposed the economical and constitutional reforms proposed by Burke and Dunning. Under Rockingham he still clung to the chancellorship, while conducting himself like a leader of the opposition. To the short-lived ministry of Shelbourne he gave a consistent support. Under the coalition of Fox and North (April to December, 1783) the great seal was placed in commission, and Lord Loughborough was made first commissioner. But Thurlow, acting as the king's adviser, and in accordance with his wishes, harassed the new ministry, and ultimately secured the rejection of Fox's India Bill (24 *P. H.*, 226). The coalition was at once dissolved. Pitt accepted office, and Thurlow again became lord chancellor (December 23, 1783). At first he supported the Government heartily, but soon his overbearing temper asserted itself. Imprudently relying on the friendship of the king, and actuated by scarcely disguised enmity to Pitt, Thurlow passed rapidly from occasional acts of hostility to secret disaffection, and finally to open revolt. He delivered himself strongly against a bill, introduced without his privity, for the restoration to the heirs of attainted owners of estates forfeited in the Jacobite rebellion of 1745. Partly to please the king and queen, partly from dislike to Burke, and partly perhaps from a real belief in the groundlessness of the accusation, he supported Warren Hastings on every occasion "with indecorous violence." His negotiations with the Whigs during the discussion of the Regency Bill (1788–19th February, 1789) went beyond the limits of mere perverse coquetry, and were designed to secure his seat on the woolsack in the event of Fox being called to power. The climax was reached in 1792, when he virulently attacked Pitt's bill "to establish a sinking fund for the redemption of the national debt," not on account of the economic objections to which it was justly liable, but on the trivial ground that it was an unconstitutional attempt to bind future parliaments. The bill was carried, but only by a narrow majority, and Pitt, feeling that co-operation with such a colleague was impossible, insisted successfully on his dismissal (June 15, 1792). The ex-chancellor, who had a few days before (June 12) been created Baron Thurlow of Thurlow, with remainder to his brothers and their male descendants, now retired into private life, and, with the exception of a futile intrigue, under the auspices of the prince of Wales, for the formation of a ministry from which Pitt and Fox should be excluded, and in which the earl of Moira should be premier and Thurlow chancellor (1797), finally abandoned the hopes of office and the dictatorship which he had so long exercised in the House of Lords. In 1795 he opposed the Treason and Sedition Bills without success. In 1801 he spoke on behalf of Horne Tooke—now his friend—when a bill was introduced to render a priest in orders ineligible for a seat in the House of Commons. His last recorded appearance in the House of Lords was on May 4, 1802. He now spent his time between his villa at Dulwich and Brighton, Bognor, Scarborough, and Bath. He died at Brighton on 12th September, 1806, and was buried in the Temple church. Thurlow was never married, but left three natural daughters, for whom he made a handsome provision. The title descended to his nephew, son of the bishop of Durham.

Lord Thurlow was a master of a coarse caustic wit, which habitually in his private and too frequently in his public life displayed itself in profanity. He was a good classical scholar and made occasional translations in verse from Homer and Euripides. His judicial and his ecclesiastical patronage was wisely exercised; he was the patron of Dr. Johnson and of Crabbe, and was the first to detect the great legal merits of Eldon. Thurlow's personal appearance was striking. His dark complexion, harsh but regular features, severe and dignified demeanor, piercing black eyes and bushy eyebrows, doubtless contributed to his professional and political eminence and provoked the sarcasm of Fox that he *looked* wiser than any man ever *was*. Yet he was far from being an impostor. By intense though irregular application he had acquired a wide if not a profound knowledge of law. Clear-headed, self-confident, and fluent, able at once to reason temperately and to assert strongly, capable of grasping, rapidly assimilating, and forcibly reproducing minute and complicated details, he possessed all the qualities which command success. His speeches in the trial of the duchess of Kingston for bigamy (20 *S. T.*, 355–651) are singularly vigorous and effective, while his famous opening in the Douglas Peerage case and his argument for the crown in Campbell *v.* Hall (20 *S. T.*, 312–316) show that he might have rendered high service to the judicial literature of his country had he relied more upon his own industry and less upon the learning of Hargrave and Kenyon.

W. R.)

THURSO, a seaport, police burgh, and burgh of barony of Caithness, Scotland, is situated at the mouth of the Thurso, on the beautiful Thurso Bay, at the northern terminus of the Highland Railway, 21 miles northwest of Wick, and 367 north of Edinburgh by rail. The new town, regularly built with broad streets and good houses, is steadily increasing in population. In Macdonald Square, now laid out with ornamental walks, there is a statue of Sir John SINCLAIR (*q.v.*). Along the sands a promenade 300 yards in length was formed in 1882. The town-hall (1870) embraces a court-room and rooms for the free public library and the museum, which contains the geological and botanical specimens of Robert Dick, the "Thurso baker," commemorated by Samuel Smiles, as well as a large collection of northern birds. In the neighborhood are large quarries for Caithness flags, which are cut and dressed in the town. They constitute the principal export, but the trade of the port is hindered by the inconvenience of the harbor. There is, however, communication with the south and west, and with Orkney by steamer from Scrabster pier, 3 miles to the north. To the east is Thurso Castle, the residence of the Ulbster branch of the Sinclairs. The population in 1871 was 3622 and in 1881 it was 4026.

Thurso was the centre of the Norse power on the mainland when at its height under Thorfinn (1014), and afterwards till the battle of Largs. Count Moddan, nephew of King Duncan, quartered his army for a time at Thurso, which he terms "the town of Caithness," and was plentifully supplied by spoil till surprised and slain by Thorkel in 1040. In the time of Malcolm II. Earl Erlend resided in the town. In 1633 it was created a burgh of barony, and was the seat of the sheriff courts of the county till they were removed to Wick in 1828.

THYME. The genus *Thymus* (nat. ord. *Labiatæ*) comprises a number of fragrant aromatic undershrubs, with very small leaves and whorls of small lilac flowers in the axils of the leaves or at the ends of the branches. The common garden thyme, a native of the Mediterranean region, is *Thymus vulgaris;* the wild thyme of our banks is *T. Serpyllum.* Marjoram (*Origanum*) is also closely allied. All these plants are remarkable for their essential oil, to which their fragrance is due. From this oil is produced by distillation a substance known as thymol, analogous to camphor. It is homologous with phenol or carbolic acid, and may be used as a disinfectant and germicide.

TIBBUS, or TUBUS, a nomad race of North Africa, occupying the eastern section of the Sahara from about 12°, where they are conterminous with the Tuareg Berbers, to about 24° E. long., and from Fezzan southwards nearly to Lake Tchad, 25° to 15° N. lat. Their westernmost settlements are the oases of Agram, Kawar, and Jebádo, their northernmost the district of Qatrún within the Fezzan frontier, while south and southeast they merge gradually in the Negroid populations of Kanem, Bornu (Tchad basin), Wadai, and northwest Dar-Fúr. But the heart of the nation is concentrated in the central region of Tibesti or Tu, whence they take their collective name of Tib-bu or Tu-bu, *i.e.*, "people of Tibesti or Tu."[1] There are two main divisions,—the northern Teda, more or less full-blood Tibbus, and the southern Dasa, more or less mixed or Negroid Tibbus. Somewhat more distantly connected with the same family are the Baele of the eastern and southeastern oases and the Zogháwa (Zaghwa) of Dar-Fúr, making a total population of about 190,000, distributed as follows:

Teda (Tibesti, Qatrún, Kawar, Agram, etc.)	29,000
Dasa (Borku, parts of Kanem, Wadai, Ennedi, and Bornu)	51,000
Baele (Ennedi, Wanyanga, Guro, Wún)	20,000
Zogháwa (north Dar-Fúr)	90,000
	190,000

The Tibbus, who are not expressly mentioned under this name by any ancient or mediæval writer, are usually identified with the Garamantes of Herodotus (iv. 183), whose capital was Garama (Edrisi's Germa) in Phazania (Fezzan), and of whom Ptolemy already spoke doubtfully as Ethiopians (Negroes?): *Ὄντων δὲ καὶ αὐτῶν ἤδη μᾶλλον Αἰθιώπων* (i. 8). But Leo Africanus transfers them to the Berber connection, whose fifth great division he deals with under the names of Gumeri (Garamantes?) and Bardæi or Bardoa, that is, the Teda of the Bardai oasis, Tibesti.[2] Lastly, Barth on linguistic grounds grouped them with the Kanúri of Bornu, who are undoubtedly Negroes; and since his time (1852–53) the Tibbus have been regarded by most ethnologists as a Negro or at least a Negroid people.[3] Nachtigal, who has studied them more carefully than any modern observer, sees good reason to challenge this conclusion (*op. cit.*, ch. vii.); and, although his own inferences are somewhat vague, he supplies sufficient evidence for a solution of this difficult ethnological problem. There can be no doubt that the Teda, or true Tibbu, probably identical with the Tedamansii, a branch of the Garamantes, placed by Ptolemy south of the Samamycii in Tripolitana,[4] are physically a Hamitic, not a Negro people, closely resembling their western Tuareg neighbors. They are a pure homogeneous race, who have for ages undergone no perceptible change in their rocky homes, and who are still distinguished by the regular features, long black ringletty hair, haughty bearing, and fierce expression common to so many of the Berber and other Hamitic peoples. Mostly of middle size, they are finely proportioned in all their limbs, except the somewhat too small hands and feet, with lighter complexion than that of the southern Dasa, and no trace of the flat nose, thick tumid lips, or other marked characteristics of the true Negro. "Their women are charming while still in the bloom of youth, unrivalled amongst their sisters of North Africa for their physical beauty, pliant and graceful figures" (Keane's *Reclus*, xi. p. 429). But there has been a general displacement of the race southwards; and, while only a few still linger in the northern Qatrún and Kufara districts, large numbers have since mediæval times penetrated into the Kanem, Bornu, Wadai, and Dar-Fúr regions of central Sudan. Here they have everywhere merged with the natives, so that in the Dasa, Kanembu, Kanuri, Baele, and Zogháwa groups the Tibbu race presents all the shades of transition between the true Negro and the true Hamite that are also found to prevail between the blacks of western Sudan and the Tuareg Berbers, and between the Nubas and other eastern Sudan Negroes and the Hamitic Gallas, Somáli, and Bejas.

The same transitional stages are observed in the Tibbu forms of speech, which constitute a wide-spread linguistic family, whose most archaic and purest branch is the Tedaga of Tibesti (Nachtigal). Through the southern Dasaga the Tedaga merges in the more highly developed and more recent Kanem, Bornu (Kanuri), Ennedi (Baele), and Dar-Fúr (Zogháwa) dialects, which, owing to the absence of grammatical gender and some other structural features, are usually classed as Negro languages. But a Negro tongue could not have arisen among the Hamites of the Tibesti uplands, and the explanation of this linguistic difficulty is obviously the same as that of the physical puzzle. The Negro affinities of the southern members of the group have arisen through assimilation with the original and now partly displaced Negro idioms of central Sudan. There remains the final difficulty that Tedaga itself has absolutely nothing in common with the Berber or any other Hamitic tongue. If therefore it is neither Hamitic nor Negro, the only two stock languages recognized by Lepsius in Africa (*op. cit.*, *passim*), how is it to be placed? First of all Lepsius's hasty generalization, wholly inconsistent as it is with the conditions occurring in other parts of the continent, must be unhesitatingly rejected. Room having thus been found for other linguistic families, the Tedaga of Tibesti may be readily explained as an independent evolution from a primeval Tibbu-Berber germ, analogous to other linguistic evolutions in other isolated or inaccessible highland regions, such as the Caucasus, the Pyrenees, and the Anahuac tableland. The common germ, essentially evanescent in its nature, has long since perished, or can no longer be detected, and the Tibbu and Berber languages stand side by side as now fundamentally distinct, while the two races still remain physically one. The Tibbus are therefore a Hamitic people, who in their secluded rocky homes have had time to evolve an independent form of speech, which southwards has become largely assimilated to the Sudanese Negro dialects.

Lying on the track of the great caravan route between Fezzan and Lake Tchad, the Tibbus have always been a predatory race, levying blackmail on the convoys passing through their territory, maintaining intertribal feuds, and carrying on constant warfare with the surrounding Berber and Sudanese populations. This, combined with the severe struggle for existence in their inhospitable upland valleys, has rendered them harsh, greedy, and suspicious,—sentiments reflected in their hard features and stern expression. Till comparatively recent times all were pagans, whence the term Kufra (Kufara), "Land of the Unbeliever," applied by the Arabs to the southern oases of Tripolitana. But for two or three centuries they have been zealous Mohammedans, and some have even lately been brought within the influence of the political Senúsíya sect (see TRIPOLI, below). They are a frugal race, living mostly on goat's milk, dates, berries, durrha, and the fruit of the dúm-palm; nevertheless they are of robust constitution and remarkably agile. They are also intelligent, crossing the wilderness by a sort of instinct quite unintelligible to the stranger, and in all ordinary transactions they display surprising tact and shrewdness. The tribal organization embraces *dardai* or headmen, *maina* or nobles, and the common folk, while the unwritten law of custom rules supreme over all classes. The women, who are orderly and industrious, are well treated, and the polygamy allowed by the law is little practiced. But the vendetta is still a social institution.

---

[1] Cf. Kanem-bu = people of Kanem, *bu* being the plural personal postfix answering to the Bantu prefix *ba*, *wa* (Ba-Suto, Wa-Ganda, etc.), and to the *be* of Fúl-be = Fúl people or Fulahs from Púl. In Tedaga the root *tu* means "rock;" hence Tu-bu = "rock-dwellers," as described by Herodotus and as explained in their Arab designation *Reshádeh*, from *reshad* = rock, hill.

[2] See Vater, *Mithridates*, ii. p. 45 of Berlin ed. 1812, and Nachtigal, *Sáhara und Sudan*, 1881, ii. p. 189.

[3] "Ursprünglich ein Negervolk," Lepsius, *Nubische Grammatik* (*Einleitung*). Berlin. 1880.

[4] The original inhabitants of the Kufara (Kufra) oasis in south Tripolitana were Teda, some of whom still survive in a small hamlet south of Jebel Nari. Since the beginning of the 18th century they have been replaced elsewhere in Kufara by the Zwiya Arabs from the Leshkerreh oases.

(A. H. K.)

TIBER. See ITALY, vol. xiii. p. 448.

TIBERIAS, now ṬABARÎYA, a city of Palestine, on the western shore of the Sea of Galilee or Lake of Tiberias, occupies a narrow strip of plain under a hill in a feverish but fertile situation. Recent estimates place the population at from 2000 to 3000,—about half the inhabitants being Jews, and many of the latter immigrants from Poland. The streets are indescribably filthy, and an Arab saying is that "the king of the fleas holds his court at Tiberias." The walls of the town and the castle on the north were in great part ruined by an earthquake in 1837, when half the population perished. The most interesting building is a very ancient synagogue by the lake, the lower story of which is said to have been unaffected by the earthquake. Outside the town are the plastered monuments ("whited sepulchres") of R. Akiba and Maimonides. Half an hour to the south are the famous hot baths mentioned by Pliny (*H.N.*, v. 15 [71]). Josephus calls this place Emmaus, which has suggested an identification with Hammoth-dor (Josh. xxi. 32) or Hammon (1 Chron. vi. 76 [61]), names which perhaps point to the existence of thermal springs.

Tiberias was founded by Herod Antipas apparently not before 26 A.D.,[1] and so was quite a new place at the time of our Lord's ministry in Galilee. And, though it became the capital of Galilee, it was at first a purely Greek city, which accounts for its not appearing among the scenes of the Galilæan ministry. It joined in the war of liberty, but yielded without resistance to Vespasian, and was restored by him to its master Agrippa, on whose death in 100 it fell directly under Roman rule. The place came to be a great seat of Jews and Jewish learning: it was the residence of R. Judah, the editor of the Mishnah; and, though the schools of Palestine were ultimately overshadowed by those of Babylonia, the school of Tiberias was still famous in the time of Jerome. According to Epiphanius, the first Christian church was built by Constantine, and from this time we hear of bishops of Tiberias. The Arabs took Tiberias in 637; it was restored to Christendom by Tancred, but yielded to Saladin in 1187 after the battle of Ḥiṭṭín. It was again in Christian hands from 1240 to 1247. In the middle of the 18th century it was one of the fortresses of the renowned Sheikh Ẓáhir, who for many years defied the Turkish power.

TIBERIUS (42 B.C.–37 A.D.), emperor of Rome, whose full name was TIBERIUS CLAUDIUS NERO, was born on the Palatine hill on 16th November, 42 B.C. When he became a member of the imperial family, the court genealogists made him out to be one of the ancient patrician Claudii; but the pedigree is at some points difficult to trace. His father, who bore the same name, was an officer of Julius Cæsar, who afterwards proposed to confer honors on the assassins, then joined Mark Antony's brother in his mad attack on Octavian, took refuge with Mark Antony, and returned to Rome when the general amnesty was proclaimed in 38 B.C. Livia, the mother of Tiberius, was also of the Claudian family, out of which her father had passed by adoption into that of the Livii Drusi. Early in 38 Livia was amicably ceded to Octavian (the future Augustus), and three months after her new marriage Drusus, brother to Tiberius, was born. Livia had no children by Augustus, and therefore devoted all her remarkable gifts to the advancement of her sons. They were treated with high consideration by the emperor, yet Augustus held firmly to the hope that his throne might be filled on his death by one in whose veins ran the blood of the Octavii; and not till Tiberius was past forty did there appear any probability that he would ever rise to be emperor. He passed through the list of state offices in the usual princely fashion, beginning with the quæstorship at the age of eighteen, and attaining the consulate for the first time at twenty-nine. From the great capacity for civil business which he displayed as emperor it may be inferred that he applied himself with determination to learn the business of government.

But from 22 to 6 B.C. and again from 4 to 10 A.D. by far the greater part of Tiberius's life was spent in the camp. His first service was as legionary tribune in one of the desperate and arduous wars which led to peace in the Spanish peninsula through the decimation, or rather the extermination, of the rebellious tribes. In 20 B.C. Augustus sent Tiberius with an army to seat Tigranes of Armenia on the throne as a Roman vassal. As Tiberius approached the frontier of Armenia, he found its throne vacant through the assassination of the king, and Tigranes stepped into his place without a blow being struck. Tiberius crowned Tigranes king with his own hand. Then the Parthian monarch grew alarmed and surrendered "the spoils and the standards of three Roman armies." The senate ordered a thanksgiving such as was usually celebrated in honor of a great victory. The following year was passed by Tiberius as governor of Transalpine Gaul. In the next year (15) he was despatched to aid his brother Drusus in subjugating the Ræti and Vindelici, peoples dwelling in the mountainous region whence the Rhine, Rhone, and Danube take their rise.[2] Drusus attacked from the eastern side, while Tiberius operated from the upper waters of the Rhine, and by stern measures the mountaineers were reduced to a state of quietude, and could no longer cut communications between northern Italy and Gaul, nor prosecute their raids in both countries. In 12 B.C. Agrippa, the great general of Augustus, to whom he may be almost said to have owed his throne, and who was its chief support, died at the age of fifty-one, leaving Julia, the emperor's only child, a widow. Agrippina,[3] daughter of Agrippa, by an earlier marriage, was wife of Tiberius, and had borne him a son, Drusus, afterwards father of Germanicus. Livia with great difficulty prevailed upon Augustus to replace Agrippa by Tiberius, who was compelled to exchange Agrippina[3] for Julia, to his bitter grief. During the year of mourning for Agrippa, which delayed his new marriage, Tiberius was occupied with a victorious campaign against the Pannonians, followed by successful expeditions in the three succeeding summers. For his victories in the Danube regions, the emperor conferred on him the distinctions which flowed from a military triumph in republican times (now first separated from the actual triumph), and he enjoyed the "ovation" or lesser form of triumphal entry into the capital. On the death of Drusus in the autumn of 9 B.C. Tiberius, whose reputation had hitherto been eclipsed by that of his brother, stepped into the position of first soldier of the empire. The army, if it did not warmly admire Tiberius, entertained a loyal confidence in a leader who, as Velleius tells us, always made the safety of his soldiers his first care. In the campaign of the year after Drusus's death Tiberius traversed all Germany between the Rhine and the Elbe, and met with slight opposition. But it would be too much to believe the statement of Velleius that "he reduced Germany almost to the position of a tributary province." He was rewarded with the full triumph, the military title of "imperator," and his second consulship, through the opposition of the powerful Sugambri had been only broken by an act of treachery, the guilt of which should perhaps be laid at the door of Augustus. In 7 B.C. there was another but insignificant campaign in Germany. Next year Augustus bestowed on his stepson the tribunician authority for five years. Tiberius was thus in the most formal manner associated with the emperor in the conduct of the government on the civil side; but Tacitus (*Ann.*, iii. 56) goes too far when he says that this promotion marked him out as the heir to the throne.

---

[2] Horace, *Odes*, iv. 14.

[3] [Vipsania, eldest daughter of Agrippa, was wife of Tiberius, and mother of Drusus Cæsar by him, and was put away for Julia.—AM. ED.]

Tiberius now suddenly begged permission to retire to Rhodes and devote himself to study. He seems to have declined absolutely at the time to state his reasons for this course, but he obstinately adhered to it, in spite of the tears of Livia and the lamentations of Augustus to the senate that his son had betrayed him. If we may believe Suetonius, Tiberius determined to commit suicide by abstention from food, and Augustus only gave way when this design was all but accomplished. The departure from Italy was as secret as it could be made. Years afterwards, when Tiberius broke silence about his motives, he declared that he had retired in order to allow the young princes, Gaius and Lucius, sons of Julia, a free course. There was perhaps a portion of the truth wrapped up in this declaration. Like Agrippa, who retired to Mytilene to avoid the young Marcellus, Tiberius had clearly no taste to become the servant of the two children whom Augustus had adopted in their infancy and evidently destined to be joint emperors after his death. But it may well be believed that Tiberius, unlike Agrippa, had no burning ambition to see himself in the place destined for his stepsons; and it may have been in his eyes one of the attractions of exile that it released him from the obligation to aid in carrying out the far-reaching designs which Livia cherished for his sake. But the contemporaries of Tiberius were no doubt right in believing that the scandal of Julia's life did more than all else to render his position at Rome intolerable. His conduct to her from first to last gives a strong impression of his dignity and self-respect. When at last the emperor's eyes were opened, and he inflicted severe punishment upon his daughter, her husband, now divorced by the emperor's act, made earnest intercession for her, and did what he could to alleviate her suffering. At Rhodes Tiberius lived simply, passing his time mainly in the company of Greek professors, with whom he associated on pretty equal terms. He acquired a very considerable proficiency in the studies of the day, among which must be reckoned astrology. But all his attempts at composition, whether in prose or verse, were labored and obscure. After five years absence from Rome, he begged for leave to return; but the boon was angrily refused, and Livia with difficulty got her son made nominally a legate of Augustus, so as in some degree to veil his disgrace. The next two years were spent in solitude and gloom. Then, on the intercession of Gaius, Augustus allowed Tiberius to come back to Rome, but on the express understanding that he was to hold aloof from all public functions,—an understanding which he thoroughly carried out.

He had scarcely returned before death removed (2 A.D.) Lucius, the younger of the two princes, and a year and a half later Gaius also died. The emperor was thus left with only one remaining male descendant, Agrippa Postumus, youngest son of Julia, and still a boy. Four months after Gaius's death Augustus adopted Agrippa and at the same time Tiberius. The emperor now indicated clearly his expectation that Tiberius would be his principal successor. The two essential ingredients in the imperial authority—the *proconsulare imperium* and the *tribunicia potestas*—were conferred on Tiberius, and not on Agrippa, who was too young to receive them. Tiberius's career as a general now began anew. In two or three safe rather than brilliant campaigns he strengthened immensely the Roman hold on Germany, and established the winter camps of the legions in the interior, away from the Rhine.

In 5 A.D. it became necessary to attack Maroboduus, who by combining peoples formerly hostile to each other had constructed a formidable power, with its centre in Bohemia, menacing the Roman acquisitions in Germany, Noricum, and Pannonia. The operations were conducted both from the Rhine and from the Danube, Tiberius being in command of the southern army. Just as the decisive engagement was about to take place, Tiberius learned that Pannonia and Dalmatia were aflame with insurrection in his rear. He was therefore forced to conclude peace on terms honorable to Maroboduus. The terror inspired in Italy by the Pannonian and Dalmatian rebellion under the able chief Bato had had no parallel since the invasion of the Cimbri and Teutones. The four serious campaigns, which the war cost displayed Tiberius at his best as a general. As he was about to celebrate his well-won triumphs, the terrible catastrophe to Varus and his legions turned the rejoicing into lasting sorrow, and produced a profound change in the Roman policy towards Germany. Although Tiberius with his nephew and adopted son Germanicus made in 9 and 10 A.D. two more marches into the interior of Germany, the Romans never again attempted to bound their domain by the Elbe, but clung to the neighborhood of the Rhine. Tiberius was thus robbed in great part of the fruit of his campaigns; but nothing can deprive him of the credit of being a chief founder of the imperial system in the lands of Europe. From the beginning of 11, when he celebrated a magnificent triumph, to the time of the emperor's death in 14 Tiberius remained almost entirely in Italy, and held rather the position of joint emperor than that of expectant heir. Agrippa Postumus had proved his incapacity beyond hope, and had been banished to a desolate island. In all probability Tiberius was not present when Augustus died, although Livia spread reports (eagerly amplified by Velleius) of an affectionate interview and a lingering farewell.

Tiberius ascended the throne at the age of fifty-six. What struck his contemporaries most was his absolute impenetrability. As was said of a very different man, the poet Gray, "he never spoke out." All his feelings, desires, passions, and ambitions were locked behind an impassable barrier, and had to be interpreted by the very uncertain light of his external acts. It is recorded of him that only once did he as commander take counsel with his officers concerning military operations, and that was when the destruction of Varus's legions had made it imperatively necessary not lightly to risk the loss of a single soldier. He was an unparaleled master of passive and silent dissimulation, and the inevitable penalty of his inscrutability was widespread dislike and suspicion. But behind his defences there lay an intellect of high power, cold, clear, and penetrating all disguises. Few have ever possessed such mental vision, and he was probably never deceived either about the weaknesses of others or about his own. For the littleness and servility of public life in regions below the court he entertained a strong contempt. It is a question whether he ever liked or was liked by a single being; but he did his duty by those with whom he was connected after a thorough though stern and unlovable fashion. As a general he commanded the full confidence of his soldiers, though he was a severe disciplinarian; yet the men of his own legions greeted his accession to the throne with a mutiny. Tiberius proved himself capable in every department of the state more by virtue of industry and application than by genius. His mind moved so slowly and he was accustomed to deliberate so long that men sometimes made the mistake of deeming him a weakling and a waverer. He was in reality one of the most tenacious of men. When he had once formed an aim he could wait patiently for years till the favorable moment enabled him to achieve it, and if compelled to yield ground he never failed to recover it in the end. The key to much of his character lies in the observation that he had in early life set before himself a certain ideal of what a Roman in high position ought to be, and to this ideal he rigidly and religiously adhered. He may in one sense be said to have acted a part throughout life, but that part had entered into and interpenetrated his whole nature. His ideal of character was pretty much that of the two Catos. He practiced sternness, silence, simplicity of life, and frugality as he deemed that they had been practiced by the Fabricii, the Curi, and the Fabii. That Tiberius's character was stained by vice before he became emperor no one who fairly weighs the records can believe. The persuasion entertained by many at the end of his life that he had been always a monster of wickedness, but had succeeded in concealing the fact till he became emperor, has slightly, but only slightly, discolored the narratives we possess of his earlier years. The change which came over him in the last years of his life seems to have been due to a kind of constitutional clouding of the spirits, which made him what the elder Pliny calls him, "the gloomiest of mankind," and disposed him to brood over mysteries and superstitions. As this gloom deepened his will grew weaker, his power tended to fall into the hands of unworthy instruments, terrors closed in around his mind, and his naturally clear vision was perturbed.

The change of masters had been anticipated by the Roman world with apprehension, but it was smoothly accomplished. Tiberius was already invested with the necessary powers, and it may even be that the senate was not permitted the satisfaction of giving a formal sanction to his accession. Agrippa Postumus was put to death; but Livia may be reasonably regarded as the instigator of this crime. Livia indeed expected to share the imperial authority with her son. At first Tiberius allowed some recognition to the claim; but he soon shook himself free, and later became estranged from his mother and held no communication with her for years before her death. The history of Tiberius's relations with other members of his family is hardly less miserable. Perhaps with any other commander than Germanicus the dangerous mutiny of the troops on the Rhine which broke out soon after Tiberius's accession would have ended in a march of the discontented legions upon the capital. The perilous episode of Arminius caused the recall of Germanicus and his despatch to the East on an honorable but comparatively inactive mission. The pride and passion of Agrippina, the granddaughter of Augustus and wife of Germanicus, tended to open a breach between her husband and the emperor. In his Eastern command Germanicus found himself perpetually watched and even violently opposed by Piso, the governor of Syria, who was suspected to have received secret orders from Tiberius. When Germanicus died at Antioch in 19 A.D., the populace of Rome combined with Agrippina in demanding vengeance upon Piso; and the emperor was forced to disown him. The death of Germanicus was followed four years later by that of Drusus. These two princes had been firm friends, and Livilla, the wife of Drusus, was sister to Germanicus. Years afterwards it was found that Drusus had fallen a victim to the treachery of his wife Livilla, who had joined her ambition to that of the emperor's minister of state Sejanus. When Drusus died, Tiberius nominated two of Agrippina's sons as his heirs. But Sejanus had grown strong by nursing the emperor's suspicions and dislike for the household of Germanicus, and the mother and the princes were imprisoned on a charge of crime. In his memoirs of his own life Tiberius declared that he killed Sejanus because he had discovered that he entertained a mad rage against the sons of Germanicus. But the destruction of Sejanus did not save Agrippina and her two children. The third son, Gaius Cæsar (Caligula), lived to become emperor when Tiberius died in 37.

Throughout his reign Tiberius strove earnestly to do his duty to the empire at large; his guiding principle was to maintain with an almost superstitious reverence the constitutional forms which had been constructed by Augustus. Only two changes of moment were introduced. The imperial guard, hitherto only seen in the city in small detachments, was by the advice of Sejanus encamped permanently in full force close to the walls. By this measure the turbulence of the populace was kept in check. The officer in command of the guard became at once the most important of the emperor's lieutenants. The other change was the practically complete abolition of the old comitia. But the senate was treated with an almost hypocritical deference, and a pedantically precise compliance with the old republican forms was observed towards the senatorial magistrates. The care expended by Tiberius on the provinces was unremitting. His favorite maxim was that a good shepherd should shear the flock and not flay it. When he died he left the subject peoples of the empire in a condition of prosperity such as they had never known before and never knew again. Soldiers, governors, and officials of all kinds were kept in wholesome dread of vengeance if they oppressed those beneath them or encouraged irregularity of any kind. Strict economy permitted light taxation and enabled the emperor to show generosity in periods of exceptional distress. Public security both in Italy and abroad was maintained by a strong hand, and commerce was stimulated by the improvement of communications. Jurisdiction both within and without the capital was on the whole exercised with steadiness and equity, and the laws of the empire were at many points improved. The social and moral reforms of Augustus were upheld and carried further. Such risings against the emperor's authority as occurred within the Roman domain were put down with no great difficulty. The foreign or rather the frontier policy was a policy of peace, and it was pursued with considerable success. With few exceptions the duties of the Roman forces on the borders were confined to watching the peoples on the other side while they destroyed each other. On the Rhine, at least, masterly inactivity achieved tranquillity which lasted for a long period.

The disrepute which attaches to the reign of Tiberius has come mainly from three or four sources,—from the lamentable story of the imperial household, from the tales of hideous debauchery practiced in deep retirement at Capreæ during the last eleven years of the emperor's life, from the tyranny which Sejanus was permitted to wield in his master's name, and from the political prosecutions and executions which Tiberius encouraged, more by silent compliance than by open incitement. The stories of immorality are recorded chiefly by Suetonius, who has evidently used a poisoned source, possibly the memoirs of the younger Agrippina, the mother of Nero. Tiberius loved to shroud himself in mystery, and such stories are probably the result of unfriendly attempts to uplift the darkness. If history ventures to doubt the blackness of Theodora, that of Tiberius grows continually lighter under the investigations of criticism. Suetonius makes the emperor's condition to have been one of mania, issuing frequently in the abandonment of all moral restraint. But in that case the authority of Tiberius, which was as firmly upheld during the years spent at Capreæ as it had been earlier, must have fallen to pieces and come to an end. With respect to Sejanus it is impossible to acquit Tiberius of blame. If he was deceived in his favorite he must have been willing to be deceived. He conferred on Sejanus a position as great as had been held by Agrippa during the reign of Augustus, and the minister was actually, and all but formally, joint emperor. Of the administrative ability of Sejanus there can be no question; but the charm and secret of his power lay in the use he made of those apprehensions of personal danger which seem never to have been absent from his master's mind. The growth of "delation," the darkest shadow that lies on the reign, was in part a consequence of the supremacy and the arts of Sejanus. Historians of Rome in ancient times remembered Tiberius chiefly as the sovereign under whose rule prosecutions for treason on slight pretexts first became rife, and the hateful race of informers was first allowed to fatten on the gains of judicial murder. Augustus had allowed considerable license of speech and writing against himself, and had made no attempt to set up a doctrine of constructive treason. But the history of the state trials of Tiberius's reign shows conclusively that the straining of the law proceeded in the first instance from the eager flattery of the senate, was in the earlier days checked and controlled to a great extent by the emperor, and was by him acquiesced in after a time with a sort of contemptuous indifference, till he developed, under the influence of his fears, a readiness to shed blood.

The principal authorities for the reign of Tiberius are Tacitus and Suetonius. The *Annals* of Tacitus were not published till nearly eighty years after the death of Tiberius. He rarely quotes an authority by name. In all probability he drew most largely from other historians who had preceded him; to some extent he availed himself of oral tradition; and of archives and original records he made some, but comparatively little, use. In his history of Tiberius two influences were at work, in almost equal strength; on the one hand he strives continually after fairness; on the other the bias of a man steeped in senatorial traditions forbids him to attain it. Tacitus is certainly not among the historians in whom our confidence grows by repeated reading. Suetonius was a biographer rather than an historian, and the ancient biographer was even less given to exhaustive inquiry than the ancient historian; moreover Suetonius was not gifted with great critical faculty, though he told the truth so far as he could see it. His *Lives of the Twelve Cæsars* was written nearly at the time when Tacitus was composing the *Annals*, but was published a little later. Velleius Paterculus is by far the oldest authority for any part of Tiberius's life. He had been an officer under Tiberius, and he eulogizes his old general enthusiastically,—feeling it necessary, however, to do less than justice to the achievements of Germanicus. To Velleius all defenders of Tiberius have eagerly appealed. In truth it is his silence alone which affords any external aid in repelling the charges of Tacitus and Suetonius, and the fact that Velleius published his work in the lifetime of his master deprives that silence of its value. The eulogy of Sejanus which is linked with that of Tiberius must needs shake faith in the scrupulousness of the author. It is still doubtful whether Dio Cassius (whose *History* ended with the year 229) in his narra-

tive of the reign of Tiberius is to any great extent independent of Tacitus. In recent times a considerable mass of inscriptions has added to our knowledge of the administration of this emperor. The chief account of Tiberius in English is that contained in Dean Merivale's *History of the Romans under the Empire*. Mr. Beesly has written an interesting defence of him in his *Catiline, Clodius and Tiberius*. The best recent history of this period is Herman Schiller's *Geschichte der römischen Kaiserzeit* (Gotha, 1883). Numerous monographs relating to the reign have appeared in recent times on the Continent. The principles of the imperial administration of the provinces by Tiberius have been treated by Mommsen in the fifth volume of his *History of Rome*, translated into English under the title of *The Roman Provinces from Augustus to Diocletian*. (J. S. R.)

TIBESTI. See SAHARA, vol. xxi. p. 157, and TIBBUS.

TIBET.

Plate IV.

TIBET,[1] Thibet, or Tübet, an extensive and highly elevated region in the heart of Asia, comprising tablelands ranging from 10,000 to 17,600 feet above sea-level. The Himalayan mountain ranges and the transverse ranges of upper Yun-nan constitute the southern scarp, the Yun-ling Mountains of China the eastern scarp, and the Kuen-Lun (Kiún-Lún) ranges the northern scarp, towards Turkestan and Mongolia; on the west, where it narrows considerably, it merges into the Pamir tablelands. Its extreme length from east to west exceeds 1600 miles; its breadth from north to south ranges from 150 miles in the west to an average of 500 in central Tibet and a maximum of 700 in the east. The area of Tibet exceeds 700,000 square miles.

Boundaries.

Much of Tibet is wholly abandoned to wild animals, and much is uncultivable and occupied only by various wandering tribes of nomads. The centres of the settled and agricultural population lie to the south, in a region named Bod-yul (meaning Bod-land) by the inhabitants, who are called Bod-pas; by the Hindus it is called Bhot, and by the Chinese Si-tsang. The greater portion of this region is governed, under the supremacy of China, by lamas and gyalpos, ecclesiastical and lay Bod-pas, the principal seat of government being at Lhása, the chief city of Bod-yul. Portions are subject to Kashmir and Nepal, and to independent chieftains, and portions are directly subject to China; but the Bod-pa ethnological element prevails more or less throughout.

Tibet was long a *terra incognita* to Europeans. It is difficult of access on all sides, and everywhere difficult to traverse. Its great elevation causes the climate to be rather arctic than tropical, so that there is no gradual blending of the climates and physical conditions of India and Tibet, such as would tend to promote intercourse between the inhabitants of these neighboring regions; on the contrary, there are sharp lines of demarcation, in a mountain barrier which is scalable at only a few points and in the social aspects and conditions of life on either side. No great armies have ever crossed Tibet to invade India; even those of Jenghiz Khan took the circuitous route *via* Bokhara and Afghanistan, not the direct route from Mongolia across Tibet. Thus it was no easy matter for the early European travellers to find their way into and explore Tibet. Friar Odoric of Pordenone is supposed to have reached Lhása *circ.* 1328, travelling from Cathay; three centuries afterwards the Jesuit Antonio Andrada, travelling from India, entered Tibet on the west, in the Manasarowar Lake region, and made his way across to Tangut and northwestern China; in 1661 Fathers Grueber and D'Orville travelled from Peking *via* Tangut to Lhása, and thence through Nepal to India; and during the first half of the 18th century various Capuchin friars appear to have passed freely between Delhi and Lhása, by way either of Nepal or Kashmir. The first Englishman to enter Tibet was George Bogle, in 1774, on an embassy from Warren Hastings to the tashi (teshu) lama of Shigatze. In 1811 Thomas Manning made his way from India to Lhása; he is the only Englishman who has succeeded in reaching the sacred city, and he had soon to leave it. During the 19th century Europeans have been systematically prevented from entering the country or speedily expelled if found in it. In 1844–46 the French missionaries Huc and Gabet made their way to Lhása from China, but were soon deported back again. In 1866 the Abbé Desgodins travelled through portions of eastern Tibet and reached Chiamdo (in Khám), but was prevented from approaching any

European travellers.

Name.

[1] The name Tibet is not, as usually alleged, unknown in the country itself, though only found there in an attenuated form. The following forms are also met with—in Chinese annals *T'u-bat* (5th cent.) and *Tie-bu-te*, *T'u-bo-te* (11th cent.); in Mongolian, *Tübet*, *Tohöt*; in Arabic, *Tubbet*; Rabbi Benjamin (1165), *Thibet*; J. de Plano Carpini (1247), *Thabet*; Rubruquis (1253), Marco Polo (1298), *Tebet*; Ibn Batuta (1340), *Thabat*; Ibn Haukal (976), Al Biruni (1020), Odoric of Pordenone (*c.* 1328), Orazio della Penna (1730), *Tibet*. A Tibetan, arriving at Darchiendo from Lhása, states that he comes from Teu-peu, meaning High or Upper Tibet,—Stod-Bod in contradistinction to Smad-Bod or Lower Tibet. The former expression, were it supported by any ancient authority, might be regarded as the etymological origin of "Tibet"; historical evidence, however, seems to indicate another source. The state of which Lhása is the capital is often called "Deba jung" or "land of the Debas" (*sdepa ljongs*). The title of the tepa lama is familiar. Chinese records say that the king of the country is called *diba*; and Joh. Grueber informs us that the king is styled *deva* or *teva*, and is descended from an ancient race of Tangut Tatars. The Chinese annals of the T'ang dynasty record that Fanni Tubat, the historical founder of a state in the east of Tibet in 433, gave to his dominion his surname of Tubat. This was a famous family name proper to several Tatar dynasties which ruled in the north and northwest of China, and belonged to the Sien-pi race, in the language of which *tubat* meant "a coverlet." An appended legend stated that the fifth ancestor of Liluku, the founder of the southern Liang dynasty and family and father of Fanni, derived the surname of Tubat, which became that of his family, from the fact that he was born in a coverlet while his mother Huykshe was sleeping. However worthless the legend, there is complete similarity between the name of the Tubat or Tobat Tatars and that of Tibet, and we may with considerable safety take the latter word as derived from the former, the fact being that it was and is still extensively used in the sense of "great," "chief," among the Tatar tribes. Tibet, however, is not the name by which the modern Tibetans designate themselves and their country. Bod-pa, "a man of Bod," Bod-yul, "country of Bod," are the expressions in current use; but what "Bod" means is uncertain. Hodgson has maintained that before the arrival of Indian teachers the people had no name for themselves or their country, and the present Bod comes from the Sanskrit *B'ót*—an opinion which, though inconsistent with the evidence collected about Tubat, is rather confirmed by a legendary account. According to that account, the country, which was occupied by a race of men not yet emerged from primitive barbarism, was originally called Bod-rgyal, *i.e.*, "Bod's victory." The secondary name then might be in its simple form Bod, a Buddhist appellative suggested by the Sanskrit homonyms of *-but* or *-b'ot*, part of the name brought in by the Tatar conquerors. Anyhow there is no occasion for the other etymologies suggested, such as that from Buddha, or that proposed by Schiefner (*t'ub* and *p'od*, both meaning "able," "capable"). An old name for Tibet in the native books is Gdong-mar-gyi-yul, "country of the red-faced men," so called apparently from the ancient national custom of painting the face red,—a practice which was forbidden by King Srong-btsan at the instance of his wife Wan ch'eng, a Chinese princess. Among the Mongols Tibet was simply called Barontala (the "right side"), in contradistinction to Dzöntala (the "left side"), which was among them the name of Mongolia. In China, during the Yuan or Mongol dynasty, it was called Wei-sze-Tsang, in which we recognize the names of the two central provinces of Dbus (Ü) and Tsang. Khachi, Khache, Khaschi, Kashi, are various forms of a term which is often met with in books as applied to a part of the plateaus of Tibet, and which cannot without difficulty be identified in positive geography. We take it to be simply a revival of the old name of the Tangut or Hia kingdom, the Khashi or Khoshi of the Mongols (982–1227), on the northeast of Tibet, on the west of the Hoang-ho, whence Ho-si in Chinese history, and perhaps the origin of the name. In the 11th century Milaraspa made use of the term K'aché for Mussulman; Huc and Gabet have reported the use of the same expression in the central provinces with a similar acceptation. A popular etymology has confounded it with the words K'a-ché for K'a-chen, literally "big mouth," which is now supposed to be its meaning when applied to Mohammedans. Kashmir is also called K'a-ché, from the fact that it is under Mohammedan rule, says Jaeschke; but, as this has been the case only since 1605, there is great probability that here the term is simply used as an abridged form of Kashmir. (T. DE L.)

closer to Lhása. Last of all the Russian Colonel Prejevalsky succeeded in exploring portions of northern Tibet, but was unable to penetrate southwards into Bodland.

Maps.

Geographers have long been in possession of maps of Tibet, compiled from surveys executed early in the 18th century by lamas, under instructions from the Jesuit fathers who made a survey of China for the emperor Kang-he. The lamas's maps were the basis of D'Anville's *Atlas*, published in 1733, and were employed by Klaproth in constructing his map of Asia in 1824; but they are generally very meagre, only reliable in the vicinity of the principal roads, and occasionally very misleading. They must have been compiled at best from rude estimates of distance and direction, and in some parts from mere hearsay or conjecture. They are, however, supposed to have been based on astronomical determinations of position; but this is improbable, for the latitudes of such important places as Lhása and Bátang are 30 to 60 miles in error. Our knowledge of the geography of the country is complete only for portions of western Tibet, which are subject to the maharajah of Kashmir, and have been regularly surveyed. This knowledge has been largely supplemented during the last twenty years by the work of natives of India—the so-called trans-Himalayan explorers of the Indian Survey, notably Pandits Nain Singh and Krishna (A—K)—who have been trained to carry route surveys through regions which they may, but Europeans may not, enter.

Geographical divisions.

Tibet is commonly divided into two parts called Great and Little Tibet, the former lying between 102° and 79° E. long., the latter between 79° and 74°. Great Tibet is broadly divisible into a western region, in which there is a considerable preponderance of tableland over hill and mountain and of lake basins over river basins, and an eastern region, in which the reverse holds good and the surface of the ground is so greatly corrugated that the natives call it *rong-rtsub*, "a rough country full of ravines." In Little Tibet the Himalayas converge towards the Kuen-Lun, and the breadth of the plateau meridionally diminishes to less than a fourth of what it attains in Great Tibet. The entire region may be broadly divided into three longitudinal zones, increasing in elevation from south to north, viz., a southern zone, which contains the centres of the settled and agricultural population; a middle zone, comprising the pasture lands of the Bod-pa nomads; and a northern zone, for the most part abandoned to wild animals, but partly occupied by tribes of Turkic and Mongolian nomads. The southern and middle zones comprise Bodland proper and are divided into four provinces, viz., Nári (Ngári, Ari) on the west, between 74° and 85° E. long.; Khám, otherwise Do-Khám, on the east, between 92° 30′ and 102°; and in the centre, Tsáng, adjoining Nári, and U or Us (otherwise Y or Wei), adjoining Khám; the two central provinces are commonly called U-tsáng, as one. A considerable belt of the middle zone is known as the Hor country. The middle and northern zones embrace the greater portion of the region known to Bod-pas as the Cháng-táng (Byán-táng, Ján-táng) or "Northern Plain," which, however, protrudes southwards and abuts upon the Himalayas from 80° to 85° E. long., thus interposing a nomad population between the settled populations to the east and the west. The northern zone merges on the west into the Pamir tablelands.

Tableland.

The tableland of Tibet attains its maximum elevation, 17,600 feet above sea-level, on the 79th meridian, in the Lingzi-táng plateau of the northern zone; thence there is a gradual fall east, west, and south, the plateau level on the 97th meridian being about 13,500 feet in the northern zone and 10,000 in the southern. Between the 82d and 90th meridians the northern zone is known only from the maps of the lamas's survey, which indicate a surface slightly corrugated with hills and containing numerous lakes, some of great size, but no rivers of importance.

Rivers.

The river basins in this zone apparently commence to the east of the 90th meridian and from them issue the Di-chu[1] (Chinese Kin-sha-kiang), whose headwaters unite at Di-chu Rab-dun in 94° 30′ E. long.; the Chiamdo river or Lan-tsan-kiang; the Hoang-ho, in about 96°, which flows through the Kiaring and Orin lakes (13,500 feet above the sea and each exceeding 80 miles in circumference) and passes northwards out of Tibet through the Kuen-Lun; and the Ja-chu or Yalung-kiang, also in about 90° E. long., which flows southwards through eastern Tibet. In the middle zone a system of lakes on the 90th meridian gives birth to the Nag-chu, which becomes the Sok-chu and lower down the Giama-Nu-chu—known to the Chinese as the Lu-tse-kiang—and, trending southwards, winds round the eastern extremity of the Himalayas. In the lower zone the Indus and the Yaro-tsanpo rise on either side of the 82d meridian and flow in opposite directions parallel to the Himalayas, and then, passing through openings in those mountains twenty degrees apart in longitude, enter India on the extreme east and west. The Lohit Brahmaputra rises behind the eastern Himalayas and flows southwestwards into India. The Giama-Nu-chu, Chiam-do-chu, and Dichu flows southwards into Burma and Yun-nan, through closely contiguous valleys between a system of meridional ranges which project as spurs from the Tibetan plateau. West of 82° a single water-parting between north and south—that of the Mus-tagh and Karakoram, sometimes called the Turkic—separates Indo-Tibetan from Turko-Tibetan waters; east of that meridian there are longitudinal water-partings between the basins of the several rivers already mentioned.

Himalayan region.

The Himalayan Mountains which constitute so considerable a portion of the southern scarp of Tibet, consist of a succession of longitudinal chains, running in general parallel to each other along the glacis of the plateau. These chains are much higher on their southern than on their northern faces, and are connected in some parts by transverse ridges, but in other parts are broken and interrupted by fissures and valleys. The principal chain is the one of high peaks covered with perpetual snow which culminates in Mount Everest, 29,000 feet above the sea. This chain may be regarded as the geographical boundary between Tibet and India. In some parts it is the water-parting; but at the several points where its continuity is broken the water-parting recedes to an inner chain on the plateau, and basins are formed between the two chains, the waters of which descend in rivers to the plains of India. The plateau is a region of plains and wide open valleys of little depth; the scarp is a region of mountains and narrow confined valleys of great depth. The narrow valleys of the scarp, being lower, are warmer and more favorably adapted for cultivation than the broad valleys of the plateau.

Cháng-táng and rong.

Higher than these last are the plains of the Cháng-táng, which are, for the most part, too high and cold for any but pastoral uses. All such tracts the inhabitants call *cháng-táng*, though the word strictly signifies "the Northern Plain;" and all tracts which contain valleys warm enough for cultivation they call *rong* (signifying a ravine or narrow valley or cleft in a hill), but more particularly the lower and warmer valleys which produce crops twice in the year; the word is also commonly employed to indicate a warm country. The alluvial beds in the valleys are composed of the débris of the surrounding rocks, laid out in horizontal deposits, which in course of time have become furrowed into gigantic ravines with a succession of narrow terraces in steps on each flank. It is on the existing lower alluvial beds and the remnants of higher beds that cultivation is carried on, in plots which are usually well watered and very fertile. The sharp needle-peaks, which are highest of all and bare of soil, but covered with perpetual snow, are met with most frequently in tracts of rong, and the rounded hills coated with grass to altitudes sometimes exceeding 16,000 feet in tracts of cháng-táng. The forest-clad mountain slopes which are occasionally met with occur chiefly in the rong. The general direction of the hill and mountain chains is east and west, but northwest and southeast in western Tibet, northeast and southwest in the province of U, and north and south in eastern Tibet. The peaks rise in many parts to between 20,000 and 25,000 feet—in the Mus-tagh range to 28,250—above the sea-level, but rarely to more than 10,000, and often to not more than a few hundred feet above the general level of the plateaus from which they spring. The principal water-partings in some districts follow the crests of low ridges and gentle undulations which are of barely appreciable elevation above the surface of the ground.

---

[1] Tibetans call rivers either *tsanpo* = river or *chu* = water, the former being chiefly employed in southern Tibet, as for the great Yaro-tsanpo (Upper river) and its principal tributaries. Lakes are called *cho* or *tso*. A mountain pass is called *lá*.

Nári.

Nári, the western province of Bodland is divided into the sub-provinces of Ladak and Balti on the west, between 75° and 79° E. long., now a part of Kashmir; Khorsum between 79° and 82°, conterminous with the Himalayan provinces of British India; and Mang-yul or Dokthol, between 82° and 87°, conterminous with western Nepal. The last two are under the government of Lhása. Western Nári is bounded on the south by that portion of the Himalayan chain of snow-peaks which stretches in almost a direct line northwest from the Manasarowar Lake region to the Nanga Parbat peak (26,620 feet), at first facing the plains of the Punjab, then passing north of Kashmir. The provinces appertaining to Kashmir have already been described in the article Ladak and Balti (*q.v.*). The Karakoram chain, although its principal pass is 18,500 feet above sea-level, nowhere rises very high above the tableland. It constitutes a portion of the water-parting between India and Turkestan, separating the Lingzi-táng plateau, the highest in all Tibet, from the broad and open valley of Chang-chenmo; it has been traced eastwards to the meridian of 82°, but no farther.

Khorsum.

Khorsum is mainly cháng-táng, but has some upland cultivation round the capital, Rudok, and in the Gartang valley, and lowland cultivation in the rong of the great plateau (120 miles long by 15 to 60 broad) of Guge or Hundes, the upper basin of the Sutlej. In this province lie, within the small area of a square degree, the sources of four great rivers—the Indus, the Yaro-tsanpo, the Sutlej, and the Karnali—the sacred lakes of Manasarowar and Rakas Tal, 15,300 feet above the sea and each 50 miles in circumference, and two famous mountains, Nimo Namling (25,360 feet) to the south, believed by the Tibetans to be their highest mountain, and to the north the sacred Kailas Gangri (21,830 feet), the Kantysee of the lamas's survey. From the Kailas Gangri a chain of hills stretches to the northwest, separating the upper basins of the Sutlej and the Indus; to the north of that another chain, running east and west, culminates in the Aling Gangri peaks (24,000 feet) and separates the Indus basin from the Pangong Lake (100 miles long, from 3 to 7 broad, and 14,000 feet in altitude), near which Rudok is situated. Roads pass from Ladak to Lhása through the plains of Rawang and Sarthol, the gold-fields of Thok Jalung and Thok Daurakpa, and the Hor country.

Mang-yul or Dokthol.

Mang-yul, or Dokthol, contains the upper basins of the Yaro-tsanpo—here known as the Nári-chu—and its principal affluents, the Cha-chu and the Charta-tsanpo. The province is wholly Cháng-táng and its population nomadic, the capital, Sarka Jong, being merely a good-sized village.

U-tsang.

The Yaro-tsanpo.

Eastern basin of Yaro-tsanpo.

The common border of the provinces of Nári and Tsáng falls nearly on the 87th meridian. Here the Cháng-táng recedes from the Himalayas, and its southern scarp, trending northeast, forms the upper fringe of tracts appertaining to U-tsáng that are capable of producing a single crop annually. This region constitutes the most important portion of the basin of the Yaro-tsanpo, for it contains the chief towns and monasteries of the settled Bod-pas. Cultivation commences on a slight scale where the river enters Tsáng on the west. The first town of any importance is Junglache (13,600 feet), on the right bank, with a large monastery, Thence goods may be taken down the river for some distance by boats of leather over a wooden framework, light enough to be carried back overland. Eighty-five miles lower down, also on the right bank, are the city of Shigatze or Digarchi (12,000 feet) and the great monastery of Tashilunpo (Teshu-Lumbo), the residence of the "tashi lama," one of two spiritual incarnations of equal rank, of which the other, the "dalai lama," resides at Lhása; the monastery contains 3500 lamas. Between Junglache and Shigatze the river receives the Raka-tsanpo from the cháng-táng on its left, and the Sákya-Jong-chu from that on its right. The latter descends from the Himalayan water-parting past the monastery of Sákya (13,900 feet), which is surrounded by cultivation and governed by a chief lama called the "sákya-gángma," who is held in considerable reverence as an avatar. At Shigatze the Yaro-tsanpo receives the Pena-Nyang-chu from a valley to the southeast which contains the towns of Pena-jong and Gyangtse-jong (13,000 feet), and numerous monasteries and villages, and through which passes the main road from Bhutan to Shigatze travelled by Bogle in 1774. A little lower down it receives from the left the Shiang-chu, which rises in the Ninchen-thangla range and flows past the town of Namling (12,200 feet, 200 houses), where sheep are employed as baggage animals. the country being too cold for donkeys and the roads too stony for yaks. Then at Shangpa (Jagsa) it receives from the right the Rong-chu from the famous Yamdok-tso or Scorpion Lake to the southeast. This lake is 120 miles in circumference, 13,800 feet above the sea, and is surrounded by villages and monasteries; its scorpion claws embrace a peninsula which rises above 16,000 feet, is grass-grown to its summit, and embosoms the Damo-tso, a sacred lake, 24 miles round and 500 feet above the main lake, which is expected some day to rise and destroy all animal life by a flood. Here the roads from India *via* Bhutan and from Shigatze to Lhása converge, and after crossing the Khamba-lá (15,000 feet) strike the Yaro-tsanpo at Chiak-jam-chori (= "the iron bridge at the rocky bank"). The river in its course from Shangpa down to this point is unnavigable, passing over rapids between precipitous hills; there is no road on either bank. A little below the bridge it receives from the left the Ki-chu, the river of Lhása (*q.v.*), the chief city of Bodland. Below the junction of the Ki-chu the Yaro-tsanpo continues its eastward course through a broad and well-peopled valley. It is crossed at Chetang by a ferry on the road from Lhása to Tawang in Bhutan *via* the Yarlung-chu valley (right bank), which is said to be the pleasantest and most populous in Tibet; fruits grow in profusion at its lower extremity and the hills are forest-clad. At Chetang the river is 350 yards broad, 20 feet deep, and 11,000 feet above the sea, and has a sluggish current. On crossing the meridian of 92° 30′ E. it passes out of the province of U into that of Khám and enters its eastern basin. After traversing the Kongbo (Khombo) district, it trends northeast for 100 miles—in general parallel with the contiguous Kongbo ranges and the distant Ninchen-thangla—and on reaching 94° turns abruptly to the south. Its course has been explored 20 miles below the bend, to Gya-la-Sindong (8000 feet), but no farther. The basin is bounded on the north and east by the continuous plateaus of Lharugo, Arig, Pemba and Lhojong, Pashu, Dainsi, and Nagong, and on the south by the inner Himalayan water-parting. Numerous tributaries join the river from both sides, but little is known of them. Those from Kongbo, Lharugo, and Arig are said to unite and join it a little abova Gya-la-Sindong, and one from Nagong a little below. This last rises near the Ata-Gang-lá, a pass over the Himalayas between the Nagong plateau and the Zayul district, and is said to be on the direct road from Lhása to Zayul *via* Gya-la-Sindong; it is probably joined by the Kenpu river of the lamas's survey, which rises in the southern scarp of the Pemba-Lhojong plateau and probably flows through the Potod and Pomed districts of Khám. The independent Lhoyul country lies to the south of the Nagong-chu (lit. "black water"). The region is generally of a comparatively low elevation, is said to have much more of rong than of cháng-táng, and probably contains much more forest and luxuriant vegetation than any other part of Tibet north of the Himalayas.

Lower Yaro-tsanpo.

The lower course of the Yaro-tsanpo has long been a matter of controversy between English and French geographers: the former have maintained, in accordance with information from natives of Tibet and Assam, that it enters the Assam valley and is the principal source of the Brahmaputra river, of which the Lohit Brahmaputra river is the eastern source; the latter have maintained, on the authority of Chinese geographers, that it flows into Burma and is the principal source of the Irawadi river. But now its eastern basin has been explored, and the Lohit Brahmaputra has been found to have its sources in a range bordering the Giama-Nu-chu; the Yaro-tsanpo must therefore necessarily pass into Assam, and measurements of the discharges of the principal rivers entering Assam from the north conclusively identify it with the Dihong. That river, which receives the Lohit Brahmaputra a little below Sadiya (450 feet above the sea), has been explored upwards into the Himalayas to a point within 100 miles of Gya-la-Sindong; but as yet nothing is known of the connecting channel, except that it must have a fall of about 7000 feet, or as much as the entire fall of the Yaro-tsanpo in its upper course of 900 miles.

South Tibetan basins.

The Tibetan basins to the south of the Yaro-tsanpo which are included between the Himalayan chains of water-parting and of high snow-peaks are the Bheri, the Kali Gandak, and the Buria Gandak, subject to Nepal; then the following, which are subject to Lhása: (1) the Tirsuli Gandak, on the direct road from Kathmandu to Dokthol *via* Kirong (9700 feet); (2) the Bhotia Kosi, through which the road from Kathmandu to Shigatze passes *via* Nilam Jong or Kuti (13,900 feet) into (3) the Arun-Barun basin, 120 miles by 30, which embraces the Dingri Maidan and Shikar Jong plateaus and the great Chomto Dong Lake (14,700 feet); this same road, after passing Sikkim and western Bhutan, where the chain of high snow-peaks, including Kanchinjinga (27,815 feet), is the water-parting, traverses (4) the Lhobra, (5) the Cha-yul, and (6) the Mon-yul basins, which are also crossed by the road between Chetang and Tawang. East of the 93d meridian the height of the peaks of the outer Himalayan chain falls to about 15,000 feet; the inner line of water-parting recedes northwards, and with it the boundary of Lhása rule. The included basins are occupied by independent semi-savage tribes,—Miris, Abors, Mishmis, etc., but about the 97th meridian Lhása rule again asserts itself. The mountains again rise to a great height in the Nechin-Gangra range, the easternmost Himalaya, which terminates about the 98th meridian in spurs thrown off to the north and south, parting the waters of the Lohit Brahmaputra and the Giama-Nu-chu. The southern spur bends westwards in horse-shoe fashion round the Zayul basin, and then merges into the range which separates upper Assam and eastern Bengal from Burma. Lhása rule extends over Zayul, and for a short distance down the valley of the Giama-Nu-chu, embracing some tracts which lie outside the geographical limits of Tibet, as lower Zayul, where the elevation falls below 4000 feet and the climate is so warm that criminals are sent there from Lhása as a punishment.

The Giama-Nu-chu.

The Giama-Nu-chu is called by the Chinese the Lu-kiang or Lu-tse-kiang. Its course is known down to about 27° 30′ N. lat., a few marches below Bonga, on the left bank, where the Abbé Desgodins established a mission station temporarily; but nothing certain is known of its lower course. It is generally believed to be identical with the Salwin river, which the Chinese also call the Lu-kiang; but the similarity of name is not conclusive of identity, for the Lu country covers a large area, and its name may be given to a second river rising among the Ly-su and Lu-tse tribes to the south. Nothing certain is known of the Salwin above 25° N. lat.; where it is crossed on the road from Tali-fu to Bamo, it is almost certainly of too small a volume to have its sources farther off than, say, 250 miles in the southern Tibetan scarp, and not far away in the heart of Tibet. There is a considerable probability that the Giama-Nu-chu is the source of the Irawadi, and thus that Chinese geographers have been right in assigning a Tibetan origin to that river, though wrong in identifying it with the Yaro-tsanpo.

Eastern plateaus.

The Dayul plateau, with the lofty mountains of Kokarpo to the north near Dayul (11,450 feet) and Dokela to the south near Bonga, lies between the Giama-Nu-chu and the Chiamdo or Lan-tsan-kiang; the latter river is believed to become the Mekong of Cambodia. The Ou-kio river of the Abbé Desgodins rises in an important valley between the Giama-Nu and Chiamdo rivers and, flowing past Dayul, joins the former above Bonga. Next comes the Makham plateau, between the Chiamdo and the Di-chu, of which the chief town (11,900 feet) is called Gartok by Tibetans and Kiangka by Chinese. East of the Di-chu or Kin-sha-kiang lie the plateaus of Batang, Litang, and Darchendo, which, though geographically and ethnologically Tibetan, are directly under China. The last two are separated by the Ja-chu, which is known as the Yalung in its southerly course to join the Kin-sha; the united streams flow eastwards through China as the Yang-tse-kiang or Blue river.

Western Hor country.

The western Hor country lies to the north, on the direct route between Ladak and Lhása; it is a region of extensive grassy plains and numerous lakes, some of great size, and occasional hill ranges, which, though often snow-covered, are of no great elevation above the tableland. It is inhabited by nomads—Cháng-pas of local origin and Khám-pas from the east—and occasional communities of gold-diggers and of traders in salt and borax, which are plentifully found on the margins of the lakes. Thok Daurakpa (15,300 feet), the centre of a large gold-field, is the chief settlement. Within a remarkable basin, surrounded by high hills and enclosing the great Dangra-Yum Lake and a cluster of small but well-built villages, Ombo, are lands which produce a profusion of barley at an altitude of 15,200 feet,—a unique instance of cultivation at so great a height, no other cultivation occurring within 300 miles on either side. The Tengri-nur or Nam-cho, 150 miles in circumference and 15,350 feet above the sea, lies to the northwest of Lhása; and beyond it there is said to be a still larger lake, the Chargut-cho, and numerous smaller lakes, to one or more of which the sources of the Giama-Nu-chu may perhaps be traced, though as a rule the lakes in this region have no outlet. The Ninchen-thangla range lies between the Tengri-nur and Lhása; it is considered by some writers to rival the Himalayas, but is probably not more than 300 miles long nor anywhere higher than 24,000 feet above the sea.

The Cháng-táng.

The Cháng-táng attains its greatest width (over 500 miles) on the meridian of 85°; north of Lhása it contracts to 400 miles, and is probably narrowest (140 miles) on the meridian of 97°. It is covered to a very considerable extent, probably everywhere below 16,000 feet, with a succulent grass, which forms from May to August the softest of green carpets and furnishes an abundance of green pasture. Willow and tamarisk are occasionally met with on the margins of the lakes; but as a rule there is little wood or scrub of any kind, and cultivation only in very exceptional localities, such as Ombo. Myriads of wild animals—chiefly the yak and the antelope, but also the ass and the camel—roam over the entire region, but mostly congregate in the uninhabited northern portion; their argols furnish a plentiful supply of fuel, without which it would be impossible for travellers to cross the country, as there are stretches of hundreds of miles in which no other fuel is procurable. As the Cháng-táng narrows to the east, its surface becomes corrugated with chains of low hills. Here too there is more marsh land than on the west: the Odontala plateau at the sources of the Hoang-ho river is described by Prejevalsky as one vast bog in summer, during the prevalence of the southwest monsoon from the Indian Ocean. The openings between the meridional hill ranges to the south permit the rain clouds to pass up to much higher latitudes before discharging their moisture than on the west, where they are faced by the great longitudinal ranges of the Himalayas.

The Kuen-Lun range.

The Kuen-Lun has been identified, geologically, by Stoliczka, as far west as the Victoria Lake on the great Pamir, in 74° E. long.; it has been surveyed between 77° and 82°, where it rises to more than 22,000 feet, and towers above the plains of eastern Turkestan. To the east it is known for some distance as the Toguz-Davan (Eleven Passes) range; Prejevalsky observed a prominent peak (Jingri, 20,000 feet) on the 90th meridian, east of which successive portions are known as the Angirtakshia, Shuga, Namohon, Burkhan Budha, and Dzunmo-Lun ranges. The rivers flowing north through openings in the Kuen-Lun are generally small, with the exception of the Hoang-ho. East of the 85th meridian the Kuen-Lun constitutes the chord of an arc formed by the Altin Tagh, Nan-shan, and Koko-nur ranges, which project northwards and border the plains of the Lob-nur region and the Chinese province of Kansuh; several hill ranges and some great plateaus—notably those of Chaidam or Tsaidam—are comprised between the arc and the chord, and the region generally is closely allied to Tibet in its physical aspects. Occasional peaks rise to considerable altitudes and are covered with perpetual snow; the plateaus form a succession of steps ascending from the plains of Gobi to the Tibetan plateau.

Commercial road from west to east.

Darchiendo, called Ta-chien-lu by the Chinese, on the extreme eastern boundary of Tibet, is the principal emporium of the trade between that country and China. Thence two important roads lead to Lhása, one called the Júng-lám or "official road" (935 miles long), the other the Cháng-lám or "northern road" (890 miles). The former, which is the more direct, is the post road and that by which officials travel between Lhása and Peking; but it crosses much rugged and difficult country. The other is preferred by traders, as being less difficult and less harassed by officials, and mostly passing over plains with an abundance of pasture for their baggage animals. The former has long been known from the published travels of Huc and Gabet and the embassies from Nepal to China, and its eastern section, from Batang to Darchiendo, has been traversed by several Europeans of late years. The latter lies in regions in eastern Tibet into which no European has yet penetrated, but which were recently crossed by Pandit Krishna from north to south; they belong to the province of Khám, which appears to be split up into a number of districts, each governed by its own gyalpo or chieftain, who in some instances is subject to Lhása, in others to China, but not unfrequently is independent of both. Darchiendo itself lies in the Minia (Miniak) district, from which the Cháng-lám passes through a succession of petty districts, Tau, Dango, Dau, and Rongbacha or Horko, skirting Niarong (Gyarung?). The inhabitants of this last are said to have conquered the neighboring districts and to have even braved the Chinese, but at last to have been won over to Lhása by bribery. Rongbacha lies in the valley of the Ja-chu and contains the large town and monastery of Kanzego (2500 houses; 2000 lamas; 10,200 feet above the sea). Beyond it lies the valley of the Di-chu, the district of Dar-ge (De-gue), said to be one of the richest and most populous in all Tibet, containing towns in which the best jewelry, saddlery, guns, and swords are manufactured. The Cháng-lám passes through Dar-ge up to Kegudo (11,800 feet), where it meets roads over the Cháng-táng from Chaidam on the north and the Koko-nur district in the northeast. Very little is known of the country between the Cháng-lám and the frontiers of China; it is called Sifan or "the country of the western barbarians" by the Chinese; to the north are the districts of Chiamogolok and Banakhasum, inhabited by marauding tribes, and lower down are the Amdo and Thochu districts, on the borders of tracts occupied by the Manchu tribes of Szechuen (China). From Kegudo the Cháng-lám trends westwards over the eastern Hor country, all cháng-táng, for 300 miles. The route has not yet been explored, but probably passes through the pasture lands of the Sok-pas; on reaching Lake Chomora it turns southwards, then passes the monastery of Shiabden (14,930 feet), a notable resting-place for caravans, crosses the lower scarp of the Cháng-táng by the Lani pass (15,750 feet), and finally descends into the Lhása plateau.

Official road from east to west.

The Jung-lám or official road from Darchiendo passes through Litang (13,400 feet; 2500 houses) and Batang (8150 feet; 2000 houses) to Gartok or Kiangka, crossing *en route* the Yalung and Kinsha rivers; thence it proceeds up the valley of the Chiamdochu or Lan-tsan-kiang, and has been traversed by the Abbé Desgodins *via* Dayag (his Tchraya) to Chiamdo (his Tchamouto). He says, "To get an idea of the configuration of the ground let any one take a sheet of parchment, crumple it in his hands into many creases, and then spread it out on a table, and he will obtain a map in relief, furrowed with depressions and steep slopes and presenting very little flat surface." Chiamdo is the chief town of the province of Khám, and, being considered a point of great strategic importance, is strongly garrisoned; it has a large monastery, containing 3000 lamas. It is situated at the junction of two rivers, which are frozen in winter; but in summer the valleys are highly cultivated. Thence the Jung-lám proceeds southwest to the bridge of Shang-ye-Jam (Kia-yu-kiao) over the Giama-Nu-chu—here called the Sok river—and then ascends to Lhojong (13,140 feet)—the Lourondson of the lamas's survey—where it is joined by the road from Gartok *via* Zayul and Nagong. It then trends westwards over the plateaus already mentioned as bordering the eastern basin of the Yaro-tsanpo, passes occasional small villages, monasteries, and lakes, crosses two lofty passes—the Nub-Gang-lá (17,940 feet) and the Tola-lá (17,350 feet)—descends to the little town of Giamda (10,900 feet) in Kongbo, and, passing out of Khám into U, enters the Lhása plateau. From the capital it is continued over a distance of about 900 miles to the western limits of Khorsum, crossing the Yaro-tsanpo at the Chiak-jam-chori bridge and recrossing at Junglache, midway passing through Shigatze; it then traverses a great breadth of cháng-táng and crosses the meridional water-parting at the Muriam-lá (15,500 feet). There are twenty-five staging places called *tarjums*, from 20 to 70 miles apart, between Lhása and Rudox, with accommodation—sometimes houses, but more generally tents—for about 200 men; they are under the charge of a *jalno*, who is bound to provide yaks and other beasts of burden and horses for carrying the mails, impressing them from the nomads encamped near the tarjums. The road is generally well defined; loose stones are cleared away in the narrow defiles, and piles of stones, surmounted by flags on sticks, are erected at places on the open stretches of tableland where the track is liable to be lost.

Climate.

The climate of Tibet differs greatly in different parts and at different seasons of the year. In western Tibet the frost is permanent from October to April, and the lakes and rivers down to 8000 feet are frozen every winter; at 15,000 feet the thermometer falls below the freezing-point every night; and at 20,000 feet there is probably perpetual frost in the shade. The mean monthly temperature and ranges of temperature, embracing from six to ten years' observations at the meteorological observatory at Leh (in 34° 10′ N. lat., height 11,540 feet), are as follows in degrees Fahrenheit:

Month.	Mean.	Range.	Month.	Mean.	Range.	Month.	Mean.	Range.	Month.	Mean.	Range.
Jan....	18.0°	28.5°	Ap'l.	42.0°	31.0°	July	61.1°	31.2°	Oct.	41.3°	30.5°
Feb ...	21.0°	30.0°	May.	48.6°	30.1°	Aug	59.6°	31.3°	Nov	32.2°	26.7°
Mar ..	32.9	28.0	June	56.4°	31.8°	Sept	52.8°	31.4°	Dec	24.8°	25.2°

At Lhása (in 29° 39′ N. lat., height 11,800 feet) the mean temperatures observed by the pandits were 36° in February and March and 61° in June and July. Southern Tibet is described as being delightful in summer,—the land covered with vegetation, streams flowing in every valley, and all nature bright, sparkling, and fresh. But in winter snow and frost reign supreme; all vegetation is dried up; the lakes and rivers are frozen; the roads and footpaths are paved with ice; and cold cutting winds sweep across the surface of the land. In northern Tibet Prejevalsky found "a terrible climate" in summer at 14,000 feet; in the second half of May wintry snowstorms were not unfrequent and the frost by night reached —9° Fahr., and in June and July there were frosts (23° Fahr.) every clear night. In the winter the cold is intense; Huc and Gabet, crossing the Di-chu river in 1846, found a great herd of yaks entombed in ice, the river having frozen whilst they were swimming across. (J. T. W.)

INDUSTRY, TRADE, AND GOVERNMENT.

Industry.

The industrial arts are at a somewhat low ebb, though in metal-founding the natives display a certain amount of ability and taste. Their statues and small bells are, however, only copies of Indian models. They use the iron from their mines, which is very good, for making excellent blades for sabres and other weapons. They are very fond of precious stones, but do not know how to work them. Their chief industries are connected with wool, the great and inexhaustible staple of the country. Weaving is generally the work of women. The cloth usually employed for summer garments is the *lwa-wa*, which is dyed with madder or indigo, and sold in pieces eight or ten inches in width and about twelve yards in length. Another sort of cloth largely sold is the *chro* or *p'rug*, of a better quality of wool, finer and thicker, which is often manufactured in Db Us (U), whence it is sometimes called Db Us p'rug; it is generally dyed dark red. *T'erma* is a superior kind of thin woollen cloth, a flannel-like fabric, dyed dark red, of which there are two sorts,—*le-t'er*, made of shawl wool, and *bal-t'er* of common wool. *Sag-lad* is for fine cloth made of fine shawl wool (*le-na*); and *snam-bu* is a woollen cloth very coarse and loosely woven, the common sort of which is not dyed.

Trade.

Every Tibetan is more or less a trader. Officers for the superintendence of trade, called *garpons*, are appointed by the king, the ministers, and the great lamaserais. The import and export traffic is carried on by caravans, which, according to the route and its difficulty employ yaks or sheep. The two great markets are Shigatze (or Digarchi) and Lhása, where the caravans arrive in December and January from China and Mongolia, Khám and Sze-chuen, Bhutan, Sikkim, and Nepal, Kashmir and Ladak. Of the four principal trade routes the two which start from Darchiendo have been mentioned above (p. 363). The third route, 915 miles in length, starting from Si-ning in Kan-su (China), runs along the Koko-nur to Jun, thence to Di-chu Rab-dun, crosses the *homa* or lower Dangla, and proceeds *via* Giaro and Lake Chomora to Lhása; this route, which is forbidden to the Chinese, is less frequented than the others because of the numerous bands of robbers infesting the country towards Si-ning. Much more important is the route which comes from the west, with Leh as its starting point; it runs *via* Gartok, Lake Manasarowar, Muriam pass, Tadom, and Shigatze to Lhása. Like the other caravans, the yearly one which follows this route stops several times on the way for local fairs; the districts passed through are compelled to furnish it with 300 yaks for carrying goods and to provide food for the travellers. The centres for Tibetan trade on the borders are—for Mongolia and north China, Si-ning; for Sze-chuen, Darchiendo; and in Assam, Davangiri and Udalguri, where there is a great fair twice a year in connection with the Tawang route. Darjiling is the central mart for the Chumbi valley trade,[1] Patna for that passing through Nepal, and Leh and Kashmir in the west. From China come silks of all varieties (Buddhist prejudice not permitting the Tibetans to rear silk-worms and kill them), carpets, and hardware; from Mongolia leather, saddlery, sheep, and horses; from Khám perfume; from Sze-chuen brick tea (some six millions of pounds annually; tea in leaf is not in use in Tibet); from Tawang, Bhutan, and Sikkim rice and tobacco; from Nepal broadcloth, silk, indigo, coral, pearls, sugar, spices, and Indian manufactures; from Ladak and Kashmir saffron and Indian commodities. Silver and gold are the most important articles of export; then follow salt, wool, woollen manufactures, furs, drugs, and musk. By the Nepal and Ladak routes Tibet exports large quantities of yaks' tails, borax, gold, silver, and ponies. In 1882-83 the total exports to India amounted to £58,322 [$283,444.92] (Punjab £17,710 [$86,170.60], North-West Provinces and Oudh £40,612 [$197,374.32]). The imports into Tibet reached £24,197 [$117,597.42] (£1530 [$7435.80] from Punjab, £22,667 [$110,161.62] from North-West Provinces and Oudh). The principal exports were borax (£17,222 [$83,698.92]), salt (£13,978 [$67,933.08]), wool and woollen goods (£4936 [$23,988.96]). The imports included grain (£13,587 [$66,032.82]), cotton goods (£2875 [$13,972.50]), and sugar (£2395 [$11,639.70]). In 1883-84 the export of borax had increased by 12,329 maunds (about 453 tons), that of wool and woollen goods by 2244 maunds (82 tons), while the exports of salt had decreased by 572 maunds (21 tons). The whole of the increase in borax is in the trade with Kumaun, and in weight it is almost double the increase in the export of rice from that district, for which it is bartered in Tibet, the usual rate of exchange being two of borax to one of rice. The total excess of the value of exports over imports amounted to nearly two lakhs of rupees. In 1885-86 the value of the wool and woollen stuffs exported rose from £4300 [$20,898] to £8800 [$42,768]. These figures, however, convey no adequate idea of the British trade with Tibet, as a large quantity of goods passes through Nepal. Russian woollen cloths, coarse and loose, of scarlet, green, blue, and violet color, as well as hearth-rugs, thickly woven and of a flowered pattern, come through Yarkand and are conveyed all over the country.

Government.

Since 1720 Tibet has been a dependency of China, and as such is under the Chinese viceroy of Sze-chuen. Chinese authority is represented by two imperial delegates, one of whom is the assistant of the other. They direct exclusively the foreign and military administration of the country, leaving the civil and religious government in the hands of the Tibetans. They are appointed for terms of three years. Subordinate to these are two *daluhi* or great officers and two paymasters, residing, one of each grade, at Lhása and at Bzhikartse (Shigatze or Digarchi). Next in rank are three commanders, residing at Lhása, Digarchi, and Dingri near the Nepal frontier. Below these are three *tingpuns*, non-commissioned officers, who complete the staff of military Chinese officers in the country. The usual number of Chinese troops, all Manchu-Tatars, in Tibet does not exceed 4500 men (2000 at Lhása, 1000 at Digarchi, 1000 at Giangchi, 500 at Dingri). In matters of civil government the supreme authority belongs to the dalai lama, the *rgyal-ba rin-po-čé*, residing in the famous temple-palace of Potala (see LHASA, vol. xiv. p. 496). But he is consulted only in cases of emergency, when his decision is never questioned. His powers are transmitted to a special officer for life, nominated by the Chinese Government, who is known by several titles, such as *de-sri* or the Mongol *nomokhan*, "king of the law"; he is the *rgyal-po* or "king" as well as the prime minister of the dalai lama, and the regent when the latter is a minor. He is selected from among the four head lamas of the Chomoling, Konduling, Tangialing, and Chajoling divisions near Lhása, so-called from their chief monasteries or *dgoṅpa* (vulg. *gomba*). Each of the four must be, like the dalai lama, an avatar, *i.e.*, when removed by death he must reappear in the flesh as a child, and be raised to that position. Of equal rank with the nomokhan is the deba lama of dGa-ldan, the great monastery near Lhása; he, however, is not an avatarian lama; his appointment has to be confirmed by the Chinese emperor. Next to him is the lama *guru* or chaplain of the dalai lama, the director of his conscience; he may be an avatar, but his nomination is also in the hands of the Chinese emperor, and this furnishes an interesting clew to the extent of the imperial power over the church of Tibet. The nomokhan rules with the help of five ministers: four of these—laymen—are for the financial, judicial, revenue, and home departments, and a fifth, a lama, for ecclesiastical affairs. The four provinces of Mngari-Khorsum, DbUs, gTsang (Tsáng), and Khams (Khám) are ruled each by a *bka-blon* or governor, with a proper staff of minor officers, under the authority of the nomokhan. Besides these there are several minor kings or rgyal-pos outside of the four provinces; but within these provinces there are four principalities which are under the direct government of the Chinese imperial delegates. These are (1) Dayag or Chraya and (2) Kiamdo or Chiamdo, both on the east; (3) bKra-šis-lhun-po or Tashilunpo, where resides the *pan-čen rin-po-čé* lama, who yields to none but the dalai lama in religious importance, and, though an avatar, requires also the confirmation of the Chinese emperor to his election; (4) Sakya-Kongma, southwest of the preceding. There is also a Chinese officer (*y-tsin*) in residence at Lhása who super-intends several minor principalities scattered over the country. Every five years Lhása, Chiamdo, and Tashilunpo send envoys with presents to the emperor. In the east of the country is the principality of Darge or Degue, in the upper course of the Yalung-kiang, ruled by a king who recognizes the suzerainty of China, and at the same time since 1863 has managed to keep on good terms with the king of Lhása, to whom he has promised submission. On the lower course of the same river are the Chentui or Gyarung tribes, who from the conquest of Tibet were subject to China, but since 1864 have been transferred by the Chinese Government to the rule of the king of Lhása, who is now represented among them by a Tibetan resident. South of the Chentui is the principality of Dar-rtse-mdo or Darchiendo, the Ta-chien-lu (Tatsienlu) of the Chinese, the rGyala of the Tibetans, where the government, under the supervision of Chinese officers, is entrusted to a native king, called Ming-chang-se by the Chinese and rGyala rgyal-po or king of rGyala by the Tibetans.

---

[1] This is still in a disturbed state, the pass being closed by the Tibetans in consequence (1) of the important preparations made in 1886 for a commercial mission to Lhása by Mr. Macaulay and (2) of the pressure of the Nepalese Government on that of Tibet in a recent treaty, in order that the whole trade should pass through Nepal.

ETHNOLOGY.

Inhabitants.

The Tibetans, in a legend of the *Tandjur*, pretend to be the descendants of an ape, sent to the snowy kingdom (*i.e.* Tibet) by Chenresig (Spyan-ras-gzígs = Avalokitêshvara), and of a Tibetan *srinmo* (a female demon or rakshasi). They had six children, whom, as soon as they were weaned, they abandoned in a forest of fruit trees. Coming back after a few years, the father found to his great surprise that their number had increased to 500. But, as they were starving, he had recourse to his patron Chenresig, who declared that he would be the guardian of the race. So he went to Mount Tise (or Kaïla the Su-Meru), and threw down a great quantity of the five kinds of grain, with which the famished apes long fed themselves. As the consequence of eating this grain the monkeys' tails and the hair on their bodies grew shorter and shorter, until they finally disappeared. The monkeys began to speak and became men, and clothed themselves with leaves. The interest of this legend, when stripped of its Buddhistic adornments, lies in the fact that belief in a monkey ancestor seems to have been common to various branches of the race. The Tang-chang and Pehlang tribes boasted also of being descended from a monkey; they were the two great divisions of the Tang-hiang or Tangut, offsets of the same Sien-pi stock as that of the conquerors of Tibet under Fanni Tubat (see note, p. 359 above). The inhabitants of Tibet belong to the Mongoloid races. Besides the Tibetans so called, occupying the greater part of the country, especially in the south from west to east, there are Turkic tribes called Hor in the northwest, Mongol tribes called Sog (Sok) in the northeast, and several ill-defined tribes on the borders of China, who differ from the others. The Tibetan race is not thoroughly homogeneous, as may be seen from the various accounts of travellers. On the west they are described as being short, with an average stature of 5 feet 2 inches, according to the measurements of General Alexander Cunningham; in central Tibet and the east they are of middle stature, rather tall than short,—a difference resulting apparently from their intermingling with the surrounding races. As general characteristics, they are strong, slender in limb, with black eyes slightly oblique, large mouth, brown hair, no beard, a clear ruddy brownish complexion with an intelligent expression. They are a people of good natural gifts, mild in temper, true to their word, kind and simple, fond of music, dancing, and singing, but thoroughly imbued with superstition and lacking enterprise. Exception is made of the people of the eastern borders, who are described as being cheats and cowards. The most highly gifted are the inhabitants of Amdo, the region beyond Khám having Koko-nur on the north and China on the east. Taller than the Tibetans of the west, they are famed for their quick intelligence and open disposition; a large proportion of the readers and chief lamas of the great schools and the higher officials belong to this race. The nomad tribes of the northeast are known by the Chinese common appellative of Sifan ("western aliens"). They include Mongol, Tibetan, and other tribes. In the east, near the borders of China, are the numerous tribes called Gyarung or Chentui; their language has been studied by Hodgson, who has pointed out its remarkable similarity of structure to that of the Tagals in the Philippines. To the south of these are the Laka or Lolo (mainly in Sze-chuen), Liso, and Moso; the last-named have advanced to some extent into Indo-China. The Laka or Lolo are remarkable for their European white features. Their language, along with that of the Liso and Moso, etc., forms a group cognate to the Burmese. Not so far east are the Lutz or Kunung, Melam, Arru, Pagny or Djion, Telu, and Remepu, all speaking a dialect of Tibetan, mixed with foreign words, for which the name of Melam is appropriate. Savages are found, says the pandit explorer A—K, in some of the valleys of the range north of Saithang (*i.e.*, the Altintagh north of the Syrten plain). They have a thick and dark skin, are well built and apparently well fed. They are clad in skins, and live in caves and dens or under the shelter of overhanging rocks. Being ignorant of the use of arms in the chase, they lie in wait for their prey near springs of water or salt flats. They are remarkable for their fleetness of foot; even a horseman finds difficulty in overtaking them. Whenever they see a civilized man they run off in great alarm. They are said to know how to kindle a fire by means of a flint; and they flay the animals they kill with sharp-edged stones. This is not the only survival of the Stone Age, for in the case of some religious rites the lamas are shaved with a "lightning stone." The country is thinly peopled and large tracts in the upper plateaus and Mngari-Khorsum are quite uninhabited. In the province of Khám the population is very irregularly distributed, and the nomad character of the tribes occupying a great part of the upper country makes any estimate doubtful. The central provinces of DbUs and gTsang are the most densely peopled, and A—K puts the population of Lhása at 25,197 (7540 being lamas). The totals lately given by Chinese authorities (4,000,000) and by the Russian staff-officers (6,000,000) are probably nearer the truth than the 11,000,000 and 33,000,000 of former authorities. The Tibetans are a very social people, and all possible circumstances, especially marriages and births, are made occasions for feasting and enjoyment. The burial customs are peculiar. First the hair is plucked out from the top of the head, in order to facilitate transmigration. The corpse is not disposed of everywhere or always in the same way (lack of fuel sometimes preventing cremation), and the lamas decide whether it is to be put away by interment, by throwing into the river, by burning, or by exposure to beasts and birds of prey. The last-named mode (regarded as very honorable) has almost disappeared in the west, but is still practiced in the central and eastern provinces; the body is cut in pieces and the bones broken into fragments by professional corpse butchers, and, when all the flesh has been devoured at the selected spot, called *dúr krod*, to which the body had been previously carried, it is not unusual to throw the remaining fragments of the broken bones into the river; sometimes the phalanges of the fingers are preserved to be used in bead-rolls. The lamas are generally inhumed in a sitting posture, the knees being brought up to the chin and corded together as tightly as possible. In the case of the gyalpos or kahlons the body is burned in a metal vessel, the ashes being afterwards carefully collected to be made into an image of the deceased. Polyandry has been practiced from the earliest times, and has been carried by the spread of the race into more genial countries, such as Bhutan. The joint husbands are usually, but not always, brothers. The arrangement seems to work smoothly, and women enjoy general consideration, according to all travellers who have spoken of the subject. The wedding ceremony takes place at the house of the bride's parents, after adequate presents have been offered by the elder brother, husband or bridegroom, and without the assistance of any priest. It consists chiefly in the engagement of the intending spouses and the placing of a piece of butter by the bride's parent on the head of the bridegroom and by his parent on that of the bride. Unless otherwise stated by the mother in each case, the elder husband is the putative father of the children, and the others are uncles. Polyandry has resulted in the assignment to the wife of a paramount position, which in the northeast and east of the country has grown among certain tribes into a real sovereignty, of which we hear from the beginnings of Chinese history, and which has left certain survivals among the Lolo and Moso tribes of the present day as well as in the late Burmese court.

Religion.

There are two religions in Tibet—Buddhism, in the shape of LAMAISM (*q.v.*), and an earlier creed, generally called the Bon religion, of which not much is known. The latter, a creed evolved from Shamanism, does not seem, from what is said in Buddhist books, to have received any regular form either in doctrine or otherwise until the introduction of Buddhism, which incited the Bonpo to seek in a better organization the means of holding their own. They borrowed much from the Buddhists, as the latter did from them,—many deities supposed to be Buddhist because of their Buddhist names being simply Bon gods. At the present day the two religions exist peaceably side by side, and the Bon creed has numerous adherents and rich convents in the central provinces of DbUs and gTsang, but few in the western and eastern provinces.

Bonpa.

The Bonpo are sometimes called the "Sect of the Black," as distinguished from the "Red" or Old and "Yellow" or Reformed Lamaists, both appellations being derived from the color of their garments, though Bonpo have been seen in red as well as in black. They are also called Gruṅ-drúṅ-pa (see below). The establishment of the Bonpa or Bon-čos, *i.e.*, the Bon religion, is attributed to Gs̀en-rábs, also called Bstan-pa Gs̀en-rábs, *i.e.*, Gs̀en-rábs of the doctrine, the name under which he is worshipped in the temples of his sect, as, for instance, at Tsodam in east Tibet, not far from Bonga; his statue, which occupies the central place, represents him as squatting with his right arm outside his red scarf, and holding in his left the vase of knowledge. In a Bon *sutra* he is said to hold in his right hand the iron hook of mercy, with which he fishes people out of the ocean of transmigration, in his left hand the seal of equality, and to wear on his head the mitra jewel. His full name is Bon gs̀en-rábs-gyuṅ-druṅ.[1] Gs̀en-rábs-mi-po, or "(the) excellent human god," another name of the same personage, has been identified by some Tibetan authorities with Lao-tsze or Lao-kiun of China. This identification, however, rests only on the slender basis of an apparent affinity of sound between the *s̀en* of *gs̀en* and a common Chinese appellative for the Taoists. The genuine resemblances between Bonpa and Taoism come from the fact that both religions have drawn from similar sources, from the native rude Shamanism which is much the same in both countries, from the tantric and esoteric doctrines of India, and from Buddhist ideas. The identity is sufficient to have deceived the uncritical mind of native scholars, and the matter has not yet been carefully examined by Europeans. The eighth book of the *Grub-mthaḥ-śel-kyi-mé-loṅ*, in twelve books, by a Tibetan lama, Chkoikyi Nyima (1674–1740), which, with three others, has been lately translated by Sarat Chandra Das (in *Jour. As. Soc. Beng.*, for 1881–1882), gives some information on the rise of the Bonpa in the region of Shang-shung, identified, not with the modern region of the same name in the northwest of Lhása, but with Gugé or Ghughè and Knáor or Upper Besahr. Three stages are pointed out in the development of the Bonpa after the time of its mythical founder, who reckoned among his spiritual descendants sages of Persia, Leg-tang-mang (some names of Lao-kiun?) of China, of Thomo, of Miniak (east Tibet), of Sumpar, and of Shang-shung. The first stage is that of the human and historical founder of the religion, a sage of the name of Shong-hon, who lived in the semi-historical time of Thi-de-tsaupo, the sixth king of Tibet (the first is said to have ruled about 415 B.C.). The second stage, dating from the 3d century B.C., is that at which Bon theories and doctrines began to exist, a beginning coincident with the arrival in the country of three Bon priests from Kashmir, Dusha, and Shang-shung. The recital down to this point gives evidence of the vagueness of the traditions preserved by the Tibetans with reference to their own beginnings, and shows that the author has striven hard to put together shreds of ancient reminiscence within a fabulous and mythical account. With the third stage we come down to historical times. It is divided into three periods,—the first dating from the arrival of an Indian pandit by way of Kashmir, who wrote some of the Bon books; the second being that of the introduction of Buddhism and the consequent persecution leading the Bonpo to multiply their sacred books, which they concealed; and the last being that of the revival of the Bonpa and the bringing forth of the hidden books subsequent to the overthrow and temporary effacement of Buddhism by gLang-dharma (908–1013). According to this source, which, however, is certainly tinged by Buddhist prejudice, it was only at the last-mentioned date that the Bonpa reached its complete organization.

Eighteen principal gods and goddesses are enumerated, including the red wrathful razor spirit, the black wrathful razor spirit, the tiger god of glowing fire (the popular god universally worshipped), the messenger demon Rgyal-po, otherwise Pe(d)kar rgyal-po (much dreaded and worshipped in the central provinces: he is said to be identical with the deity Kye-páng of Lhása, figured as a wooden stick or log decked with rags; see Jaeschke, *Dict.*, p. 7), the god of sound, the great demon, and the serpent demon. Information is lacking as to the specific characteristics of these gods, and it is not clear to which of them belongs the title of *kun-tu bzang-po*, frequently cited as the chief Bon god; he is reputed to have a wife Yom-ki-long-mo, the eternal female principle, and from their union have resulted all the minor gods and the whole world.

Bonpa literature.

Of the Bonpa literature the only text which has been made accessible to Western scholars is a sutra translated by A. Schienfer in *Mém. de l'Acad. de St. Pétersb.* (xxviii., No. 1) called *Gtsangma klu hbum dkar-po* ("The holy white nâga, the hundred thousand"); but Buddhist influence is so manifest in it that no correct idea of the primitive Bon religion can be derived from it. In a native account, dating from the 18th century and translated by Sarat Chandra Das, the following are enumerated—three works on philosophy and metaphysics, four meditative works, nine ritual serials, six series of epistles, and four mystic works of a late period, in all of which the title of the translated sutra is not made known. It is stated in the translation that these Bon scriptures originally consisted of wholesale plagiarisms, subsequently altered in orthography and terminology from Buddhist canonical works. The Bonpo are said to have got the counterparts of the *Kah-gyur* in general. As a correlative of the six-syllable prayer of the lamas *ōm mani padme hūm* (vulgarly "om-mani pémé-on"), they have one in eight syllables, which they pronounce *ma-tri-mu-tre-sa-la-dzu*. The Bonpo are now frequently confounded with the Red Lamas or Buddhists of the Old school, who are distinguished from the Yellow or Reformed sect by their garments.

HISTORY.

History.

From the 11th century B.C. the Chinese used to call by the name of Kiang the tribes (about 150 in number) of nomads and shepherds in Koko-nur and the northeast of present Tibet; but their knowledge continued to be confined to the border tribes until the sixth century of our era. In the annals of the T'ang dynasty it is said that the population of the country originated from the Bat-Kiau or Fah Kiang; and, as the information collected in the first part of the notice concerning Tu-bat, afterwards Tu-ban, the modern Tu-fan, dates partly (as is proved by internal evidence) from a time anterior to the T'ang dynasty (618 A.D.), some degree of reliance may be placed on its statements. There we are told that Fanni, a scion of the southern Liang dynasty of the Tu-bat family (which flourished from 397 to 415 at Liang-chu in Kan-suh), who had submitted to the northern Liang dynasty, fled in 433 with all his people from his governorship of Lin-sung (in Kan-chu) westwards across the Yellow river, and founded beyond Tsih-shih ("heapy stones") a state amidst the Kiang tribes, with a territory extending over a thousand *li*. By his mild and just rule he was soon enabled to establish his sway over an immense territory. His original state was apparently situated along the upper course of the Yalung river, an affluent of the Kin-sha-kiang. The foregoing statements, which are most probably genuine history, are preceded in Tibetan chronicles by a mass of legends invented by the native Buddhist historians for the purpose of connecting their monarchy with India.

Through the exertions of Prinsep, Csoma de Körös, E. von Schlagintweit, and Sarat Chandra Das we possess five copies of lists of kings, forming the royal canon of Tibet from the legendary beginnings between the 5th and 2d century B.C. down to the end of the monarchy in 914. But the serious divergences which they show (except as to the later times and in general outlines) make their unauthentic character plain. As the last published list is accompanied by a commentary, it is the easiest to follow, and requires only to be supplemented here and there from the other lists and from the Chinese sources. The first king, Gnya-khri btsan-po, is said to have been the fifth son of King Prasenadjit of Kosala, and was born with obliquely drawn eyes. He fled north of the Himalayas into the Bod country, where he was elected king by the twelve chiefs of the tribes of southern and central Tibet. He took up his residence in the Yarlung country south of Lhása. This Yarlung, which borrowed its name from the Yalung of the state of Fanni Tu-bat, is a river which flows into the Yaro-tsanpo. The first king and his six successors are known as the seven celestial *khri*; the next series consists of six kings known as the earthly *legs*; and they were followed by eight terrestrial *ldé*. This threefold succession is apparently an imitation or a debased form of the ancient legend of heavenly, earthly, and human rulers, which was carried into Persia and China, and from the latter country into Japan and Tibet,—the relative number of kings being altered in the last-named countries to suit local convenience and the small amount of truth which they contain. Whilst giving an Aryan descent to their first kings, the ancient Tibetans assigned to their princesses a divine origin, and called them *lhamo*, "goddess." The gynæcratic habits of the race are manifested in the names of all these kings, which were formed by a combination of those of their parents, the mother's generally preceding that of the father. The *ldé* kings were followed by four rulers simply called *btsan* ("mighty").

Then occurs a break in the lineal descent, and the king next in order (c. 461) may be the Tatar Fanni Tu-bat, but most probably his son and successor. His name was Lha-tho thori gnyan-btsan, otherwise Gnyan-btsan of Lha-tho thori, according to the custom usual in Tibet of calling great personages after the name of their birthplace. Lha-tho means "heaps of stones," and therefore appears to be a translation of Tsih-shih, "heapy stones," the country mentioned in connection with the foundation of a state by Fanni Tu-bat. It was during his reign that the first Buddhist objects are reputed to have reached Tibet, probably from Nepal. Little is said of his three immediate successors. The fourth was gNam-ri srong btsan, who died in 630. During his reign the Tibetans obtained their first knowledge of arithmetic and medicine from China; the prosperity and pastoral wealth of the country were so great that "the king built his palace with cement moistened with the milk of the cow and the yak." To the same king is attributed the discovery of the inexhaustible salt mine called Chyang-gi-ts'wa (Byang-gi-ts'wa = "northern salt"), which still supplies the greater portion of Tibet. The reign of his illustrious son, Srong btsan sgam-po, opened up a new era; he introduced Buddhism and the art of writing from India, and was the founder (in 639) of Lha-ldan, afterwards Lha-sa. He was greatly helped in his proselytism by his two wives, one a Nepal princess, daughter of King Jyoti varma, the other an imperial daughter of China; afterwards, they being childless, he took two more princesses from the Ru-yong (= "left corner"?) and Mōn (general appellative for the nations between Tibet and the Indian plains) countries. As a conqueror he extended his sway from the still unsubdued Kiang tribes of the north to Ladak in the west, and in the south he carried his power through Nepal to the Indian side of the Himalayas. How far southward this dominion at first extended is not known; but in 703 Nepal and the country of the Brahmans rebelled, and the Tibetan king, the third successor of Srong btsan sgam-po, was killed while attempting to restore his power. It is rather curious that nothing is said of this Tibetan rule in India, except in the Chinese annals, where it is mentioned until the end of the monarchy in the 10th century, as extending over Bengal to the sea,—the Bay of Bengal being called the Tibetan Sea. J. R. Logan has found ethnological and linguistic evidence of this domination, which was left unnoticed in the Indian histories. Mang-srong mang btsan, the second son and successor of Srong btsan sgam-po, continuing the conquests of his father, subdued the Tukuhun Tatars around the Koko-nur in 663, and attacked the Chinese; after some adverse fortune the latter took their revenge and penetrated as far as Lhása, where they burnt the royal palace (Yumbu-lagang). Khri lde gtsng-brtan-mesag-ts'oms, the grandson of Mang-srong and second in succession from him, promoted the spread of Buddhism and obtained for his son, Jangts'a Lhapon, who was famous for the beauty of his person, the hand of the accomplished princess Kyim-shang, daughter, otherwise *kung-chu*, of the Chinese emperor Juytsung. But the lady arrived after the death of her betrothed, and after long hesitation became the bride of the father. She gave birth in 730 to Khri srong ldeu btsan,[1] in the Buddhist annals the most illustrious monarch of his country, because of the strenuous efforts he made in favor of that religion during his reign of forty-six years (743–789). His son and successor Muni btsan-po, being determined to raise all his subjects to the same level, enacted that there should be no distinction between poor and rich, humble and great. He compelled the wealthy to share their riches with the indigent and helpless, and to make them their equals in respect of all the comforts and conditions of life. He repeated this experiment three times; but each time he found that they all returned to their former condition, the rich becoming still richer and the poor still poorer. The sages attributed this curious phenomenon to the good and evil acts of their former lives. Nothing of importance occurred during the following reigns, until that of Ralpachen, who won glory by his care for the translations of the Buddhist scriptures which he caused to be completed, or rewritten more accurately when required. In this reign a severe struggle took place with China, peace being concluded in 821 at Ch'angngan and ratified at Lhása the following year by the erection of bilingual tablets, which still exist. Ralpachen was assassinated by the partisans of gLang-dharma and the country fell into disorder. gLang-dharma instituted a violent persecution of Buddhism; but he was soon assassinated in his turn, and the kingdom divided into a western and an eastern part by his two sons. The partition did not, however, prevent internecine wars. The history for some time now becomes rather intricate, and requires some attention. Pal K'or tsan, the second western king, after a reign of thirteen years died leaving two sons, Thi Taši Tsegpa-pal and Thi Kyida Nyimagon. The latter went to Ngari (Mngari) and founded the capital Purang; he left three sons, of whom the eldest declared himself king of Mang-yul (the Monhuil of our maps), the second seized Purang, and the youngest, Detsud-gan, became king of the province of Shang-shung (the modern Ghughè). The revival of Buddhism began with the two sons of the last-named, the elder of whom became a monk. The younger, Khorré, inherited his father's throne, and was followed in his authority by twenty successors. Taši Tsegpa also had three sons,—Palde, Hodde, and Kyide. The descendants of the first made themselves masters of Gung-t'ang, Lugyalwa, Chyipa, Lhatse, Langlung, and Tsakor, where they severally ruled as petty chiefs. The descendants of Kyide spread themselves over the Mu, Jang, Tanag, Yarulag, and Gyaltse districts, where they also ruled as petty princes. Hodde left four sons—Phabdese, Thide, Thich'ung, and Gnagpa. The first and fourth became masters of Tsangrong, the second took possession of Amdo and Tsongkha, the third became king of DbUs, and removed the capital to Yarlung, south of Lhása. He was followed on his throne from son to son by eleven successors. History is silent as to the fate of the eastern king, the other son of gLang-dharma, and his successors, but the geographical names of the chieftainships enumerated above make it clear that the western kingdom had extended its power to the east. Chronology is deficient for all that period. While the dynasty of Khorré in Shang-shung and that of Thich'ung in DbUs were running, another authority, destined to become the superior of both, had arisen in Tibet. Khorré left his throne to his son Lhade, who was himself succeeded by his three sons, the youngest of whom invited the celebrated Indian Buddhist, Atisha, to leave his monastery Vikrama Shila for Tibet, where he settled in the great lamaserai of Thoding in Ngari. Besides religious books and teachings, he introduced in 1026[2] the method of computing time by cycles of sixty years, "obtained from the Indian province of Shambala." He was the first of the several chief priests whose authority became paramount in the country. The kings of DbUs greatly patronized them, as for instance in the case of the celebrated Sakya Pandita by the seventh of these kings. Pandita, at the special request of Kuyuk, the successor of Ogdai, paid a visit to his court in 1246–48. Five years afterwards Kublai Khan conquered all the east of Tibet; and, after he had ascended the throne of China, the Mongol emperor invited to his court Phagspa Lodoi Gyaltshan, the nephew of the same Pandita. He remained twelve years with the emperor, and at his request framed for the Mongol language an alphabet imitated from the Tibetan, which, however, did not prove satisfactory, and disappeared after eighty-five years without having been very largely used. In return for his services, Kublai invested Phagspa with sovereign power over (1) Tibet proper, comprising the thirteen districts of U and Tsáng, (2) Khám, and (3) Amdo. From this time the Sakya-pa lamas became the universal rulers of Tibet, and remained so, at least nominally, under twenty-one successive lamas during seventy years (1270–1340). Their name was derived from the Sakya monastery, which was their cradle and abode, and their authority for temporal matters was exercised by specially appointed regents. When the power of the Sakya began to wane, that of the rival monasteries of Digung, Phagdub, and Tshal increased largely, and their respective influence and authority overbalanced that of the successors of Phagspa. It was at this troubled epoch that Chyang Chub Gyaltshan, better known as Phagmodu from the name of his native town, appeared on the scene. He subdued Tibet proper and Khám, for the continued possession of which he was, however, compelled to fight for several years; but he succeeded in the long run, and with the approval of the court of Peking established a dynasty which furnished twelve rulers in succession. When the Mongol dynasty of China passed away, the Mings confirmed and enlarged the dominion of the Tibetan rulers, recognizing at the same time the chief lamas of the eight principal monasteries of the country. Peace and prosperity gradually weakened the benign rule of the kings of this dynasty, and during the reign of the last but one internecine war was rife between the chiefs and nobles of U and Tsáng. This state of things, occurring just as the last rulers of the Ming dynasty of China were struggling against the encroachments of the Manchus, their future successors, favored the interference of a Khoskot Mongol prince, Tengir To, called in the Tibetan sources king of Koko-nur. The Mongols were interested in the religion of the lamas, especially since 1576, when Altan, khakan of the Tumeds, and his cousin summoned the chief lama of the most important monastery to visit him. This lama was Sodnam rGyamtso, the third successor of Gedundub, the founder of the Tashilumbo monastery in 1447, who had been elected to the more important abbotship of Galdan near Lhása, and was thus the first of the great, afterwards dalai, lamas. The immediate successor of Gedundub, who ruled from 1475 to 1541, had appointed a special officer styled *depa* to control the civil administration of the country. To Sodnam rGyamtso the Mongol khans gave the title of Vadjra Dalai Lama in 1576, and this is the first use of the widely known title of dalai lama. During the minority of the fifth (really the third) dalai lama, when the Mongol king Tengir To, under the pretext of supporting the religion, intervened in the affairs of the country, the Pan-ch'en Losang Ch'o-kyi Gyal-ts'ang lama obtained the withdrawal of the invaders by the payment of a heavy war indemnity, and then applied for help to the first Manchu emperor of China, who had just ascended the throne. This step enraged the Mongols, and caused the advance of Gushri Khan, son and successor of Tengir To, who invaded Tibet, dethroned all the petty princes, including the king of Tsáng, and, after having subjugated the whole of the country, made the fifth dalai lama supreme monarch of all Tibet, in 1645. The Chinese Government in 1653 confirmed the dalai lama in his authority, and he paid a visit to the emperor at Peking. The Mongol Khoskotes in 1706 and the Sungars in 1717 interfered again in the succession of the dalai lama, but the Chinese army finally conquered the country in 1720, and the present system of government was established. The events which have happened since that time have been recorded in the articles LHASA and LADAK.

---

[1] The term *gyuṅ-druṅ* (*svasti*), also applied to his followers, means the cross cramponnée, the *svastika*, similar to that of the Buddhists, from which it differs only in direction, the Bonpo manner of circumambulation round a shrine or deity being from right to left, while the Buddhist manner is from left to right.

---

[1] [As King Kir Song de Tsan, this monarch is described somewhat differently in LĀMĀISM vol. xiv. p. 229.—AM. ED.]

[2] [Dr. Rhys Davids says "Atisha came to Tibet in 1041." See LĀMĀISM, vol. xiv. p. 230.—AM. ED.]

LANGUAGE[1] AND LITERATURE.

Language.

Bod-skad is the general name of the language of Tibet, which is also occasionally called Gangs-čan-gyi skad (*i.e.* "the glaciers language"). This name is specially applied to the forms in use in DbUs-gTsang. The vernacular is called *p'ál-skad* or common language in contradistinction to the *čos-skad* or book language. Besides the Bod-skad there are two chief dialects[2] in Great Tibet,—that of Khams, spoken in the three provinces of Mdo (Darrtse-mdo), Khám, and Gong in the east, and that of Ngari-Khorsum in the west. Jaeschke arranged these dialects under three heads,—(1) western, including those of Balti and Purig, the most archaic, and of Ladak and Lahul; (2) central, including those of Spiti and of DbUs and gTsang; (3) Khams. To the same Bhot group belong the Changlo or Bhutani or Lhopa, the language of Bhutan, of which we have a grammatical notice by Robinson (1849), and the Serpa and the Takpa, of Tawang, both of which are only known through the vocabularies collected by Hodgson. The later Takpa forms the transition between the Bhot group and the Si-fan group, which includes the Miniak, Sungpan, Lifan, and Thochu dialects, spoken near the eastern boarders as well as the Horpa spoken on a larger area west of the preceding, and much mixed with Turkic ingredients. With the exception of the Sokpa, a Mongol dialect, and of the Gyarung, a pre-Chinese dialect, the languages spoken in Tibet belong to the large linguistic family commonly called Tibeto-Burman, a division of the Kuen-lun group, which is a part of the Turano-Scythian stock.

Grammar.

The language is more consonantal than vocalic, though much softened in the central dialect. The consonants, 30 in number, which are deemed to possess an inherent sound *a*, are the following: *ka, k'a, ga, nga, ča, čа, dja, nya, ta, t'a, da, na, pa, p'a, ba, ma, tsa, ts'a, dza, wa, zha, za, 'h, ya, ra, la, sha, sa, ha, 'a;* the so-called Sanskrit cerebrals are represented by the letters *ta, t'a, da, na, sha* turned the other way. *Ya*, when combined as second consonant with *k-, p-, m-*, is written under the first letter. *Ra*, when combined as second letter with *k-, t-, p-*, is written under the first, and when combined with another consonant as first letter over the second. The vowels are *a, i, u, e, o*, which are not distinguished as long or short in writing, though they are so in the vernaculars in the case of words altered by phonetic detrition. Agglomerations of consonants are not objectionable; and they are often met with as initials, giving the appearance of telescoped words—an appearance which historical etymology often confirms. Many of these initial consonants are silent in the softer dialects of the central provinces, or have been resolved into a simpler one of another character. The language is much ruled by laws of euphony, which have been strictly formulated by grammarians. Among the initials, five, viz., *g, d, b, m, 'h*, are regarded as prefixes, and are called so for all purposes, though they belong sometimes to the stem. As a rule none of these letters can be placed before any of the same organic class. Post-positions, *pa* or *ba* and *ma*, are required by the noun (substantive or adjective) that is to be singled out; *po* or *bo* (masc.) and *mo* (fem.) are used for distinction of gender or for emphasis. The cases of nouns are indicated by suffixes, which vary their initials according to the final of the nouns. The plural is denoted when required by adding one of several words of plurality. When several words are connected in a sentence they seldom require more than one case element, and that comes last. There are personal, demonstrative, interrogative, and reflexive pronouns, as well as an indefinite article, which is also the numeral for "one." The personal pronouns are replaced by various terms of respect when speaking to or before superiors, and there are many words besides which are only employed in ceremonial language. The verb, which is properly a participle, has no element of person, and denotes the conditions of tense and mood by an external and internal inflection, or the addition of auxiliary verbs and suffixes when the stem is not susceptible of inflection. The conditions which approximate most closely to our present, perfect, future, and imperative are marked either by aspiration of the initial or by one of the five prefix consonants according to the rules of euphony, and the whole looks like a former system thrown into confusion and disorder by phonetic decay. As to the internal vowel, *a* or *e* in the present tends to become *o* in the imperative, the *e* changing to *a* in the past and future; *i* and *u* are less liable to change. A final *s* is also occasionally added. Only a limited number of verbs are capable of four changes; some cannot assume more than three, some two, and many only one. This deficiency is made up by the addition of auxiliaries or suffixes. There are no numeral auxiliaries or segregatives used in counting, as in many languages of eastern Asia, though words expressive of a collective or integral are often used after the tens, sometimes after a smaller number. In scientific and astrological works, the numerals, as in Sanskrit, are expressed by symbolical words. In the order of the sentence the substantive precedes the adjective and the verb stands last; the object and the adverb precede the verb, and the genitive precedes the noun on which it depends. An active or causal verb requires before it the instrumental instead of the nominative case, which goes only before a neuter or intransitive verb. The chief differences between the classical language of the Tibetan translators of the 9th century and the vernacular, as well as the language of native words, existed in vocabulary, phraseology, and grammatical structure and arose from the influence of the translated texts.

---

[1] The Capuchin friars who were settled in Lhása for a quarter of a century from 1719 studied the language; two of them, Francisco Orazio della Penna, well known from his accurate description of Tibet, and Cassian di Macerata sent home materials which were utilized by the Augustine friar Aug. Ant. Georgi of Rimini (1711–97) in his *Alphabetum Tibetanum* (Rome, 1762, 4to), a ponderous and confused compilation, which may be still referred to, but with great caution. The Tibetan characters were drawn by Della Penna, and engraved by Ant. Fontarita in 1738. In 1820 Abel Rémusat published his *Recherches sur les Langues Tartares*, a chapter of which was devoted to Tibetan. The next work of importance was a dictionary, intended for European students, which was published, with Tibetan types, at the expense of the East India Company, in 1826 at Serampur, and edited by John Marshman, from a MS. copy made by Fr. Chr. G. Schroeter, a missionary in Bengal, who had substituted English for the Italian of the original. It was the unsifted result of the labors of an unknown Italian missionary, who had been stationed either in eastern Tibet or close to the frontier in Bhutan. It was properly a collection of all the sentences he could get written by a native teacher, completed with extracts from the *Padma tangyig*, a popular series of legends about Padma Sambhava. Unfortunately the work was left unfinished, and unrevised, as there was no Tibetan scholar to correct the proofs. Though richer in words than later dictionaries, the work cannot, for these reasons, be accepted as an authority on any doubtful point. The grammatical notice, consisting of forty pages from Schroeter, prefixed to this *Dictionary of the Bhotanta, or Butan Language*, hardly deserves mention. At Calcutta in 1834 the Hungarian Alexander Csoma de Körös (1784–1842) brought out his *Dictionary, Tibetan and English*, and his *Grammar of the Tibetan Language in English*, prepared on the western frontier, where he had resided for several years at the monasteries of Yangla and Pukdal in Zanskar, and finally at Kanum in Upper Besahr enjoying the help of native scholars. His works are admirable so far as concerns the literary language (chiefly that of the Buddhist translations). At St. Petersburg, J. J. Schmidt published his *Grammatik der Tibetischen Sprache* in 1839 and his *Tibetisch-Deutsches Wörterbuch* in 1841, but neither of these works justified the great pretensions of the author, whose access to Mongolian sources had enabled him to enrich the results of his labors with a certain amount of information unknown to his predecessors. In France, P. E. Foucaux published in 1847 a translation from the *Rgya tcher rol pa*, the Tibetan version of the *Lalita Vistara*, and in 1858 a *Grammaire Thibétaine;* while Ant. Schiefner had begun at St. Petersburg in 1849 his series of translations and researches. His *Tibetische Studien* (1851–68) is a valuable collection of documents and observations. In 1861 Lepsius published his paper *Über Chinesische und Tibetische Lautverhältnisse;* and since 1864 Léon Feer has brought out in Paris many translations of texts from Tibetan Buddhist literature. In 1849 the *Journal* of the Asiatic Society of Bengal published comparative vocabularies of spoken and written Tibetan by Bryan H. Hodgson, and grammatical notices of Tibetan (according to Csoma's grammar) and of Changlo, a Tibetan dialect, by W. Robinson. But it was at Singapore in 1852 that the general relationship of the Tibetan and the Burman, now admitted in comparative philology, was established for the first time, by J. R. Logan, in the *Journal of the Indian Archipelago.* Prof. Max Müller, in his "Letter on the Classification of the Turanian Languages" of 1853, arrived independently at a similar conclusion. In 1857 the Moravian missionaries established a station at Kyelang, district of Garza, British Lahul, in Ladak, a school, and a lithographic press, and it is to the labors of H. A. Jaeschke of this mission that we are indebted for the most valuable materials for the practical study of Tibetan. From 1860 to 1867 that scholar made several important communications, chiefly with reference to the phonetics and the dialectical pronunciation, to the academies of Berlin and St. Petersburg, and in the *Journal* of the Asiatic Society of Bengal. In 1868 at Kyelang he published by lithography *A Short Practical Grammar of the Tibetan Language, with special reference to the spoken dialects*, and the following year a *Romanized Tibetan and English Dictionary.* He also published in 1871–76, at Gnadau in Prussia, by the same process a Tibetan and German dictionary. Afterwards he prepared for the English Government *A Tibetan-English Dictionary, with special reference to the prevailing dialects*, in 1881. Dr. H. Wenzel, one of his pupils, brought out in 1883 from his MS. a *Simplified Tibetan Grammar.* Major Th. H. Lewin with the help of a lama compiled *A Manual of Tibetan*, or rather a series of colloquial phrases, which was brought out at Calcutta in 1879. A portion of the New Testament has been translated into Tibetan. As regards native philology, the most ancient work extant is a grammar of the Tibetan tongue, by Tonmi Samb'ota, the introducer of the Indian alphabet, preserved in the *Bstan-hgyur* (mdo cxxiv.). This collection also contains other works of the same kind, dictionaries by later writers, translations of many Sanskrit works on grammar, vocabulary, etc., and bilingual dictionaries, Sanskrit and Tibetan. As separate publications there are several vocabularies of Chinese and Tibetan; Mongol and Tibetan; Chinese, Manchu, Mongol, Oelöt, Tibetan, and Turkish; Tibetan, Sanskrit, Manchu, Mongol, and Chinese.

[2] There are without doubt many minor *skad-lugs* or dialects which are still unknown. For instance, in the Pan-yul valley north of Lhása the inhabitants are said to speak an indistinct skad-lugs.

Philology.

The Tibetan language, in its written and spoken forms, has a great interest for philologists, on account of its bearing on the history of the so-called monosyllabic languages of eastern Asia. Is the Tibetan a monosyllabic language passing to agglutination? or the reverse? The latter is the fact, as we shall see further on. The whole question has turned upon the elucidation of the phenomenon of the silent letters, generally prefixed, which differentiate the spelling of many words from their pronunciation, in the central dialect or current speech of Lhása. As long as the sounds of this dialect only were known, the problem could not be fully grasped. Rémusat rather dubiously suggested, while Schmidt and Schiefner maintained, that the silent letters were a device of grammarians to distinguish in writing words which were not distinguished in speech. But this convenient opinion was not sufficient for a general explanation, being supported by only a few cases. Among these are—(*a*) the addition of silent letters to foreign words in analogy with older terms of the language (*e.g.*, the Persian *tadjik* was transcribed *staggzig* or "tiger-leopard," because the foreign term left untouched would have been meaningless for Tibetan readers); (*b*) the addition for the sake of uniformity of prefixed letters to words etymologically deprived of them; (*c*) the probable addition of letters by the Buddhist teachers from India to Tibetan words in order to make them more similar to Sanskrit expressions (for instance, *rje-* for "king," written in imitation of *raja*, though the original word was *je* or *she*, as is shown by cognate languages). On the other hand, while phonetically the above explanation was not inconsistent with such cases as r*ka*, d*kah*, b*kah*, bs*ka*, and *nga*, r*nga*, *ngag*, s*ngags*, l*nga*, *nga*d, and brt*se*, brd*zun*, db*yar*, etc., where the italicized letters are pronounced in full and the others are left aside, it failed to explain other cases, such as *dgra*, *mgron*, *spyod*, *spyan*, *sbrang*, *sbrul*, *bkra*, *k'ri*, *krad*, *k'rims*, *k'rus*, etc., pronounced *ḍa*, *ḍon*, *ĉod* or *šwod*, *čen*, *dang*, *ḍeu*, *ṭa*, *t'i*, *tad* or *teh*, *t'im*, *tu*, etc., and many others, where the spoken forms are obviously the alteration by wear and tear of sounds originally similar to the written forms. Csoma de Körös, who was acquainted with the somewhat archaic sounds of Ladak, was able to point to only a few letters as silent. But Major Cunningham, in his book on the same country (1854), held that the Tibetan writing, when first applied to the language, was the faithful transcription of speech, and he gave as a proof that the name of the province of U, written DbUs, was the *Debasæ* of Ptolemy. Foucaux, in his *Grammaire* (1858), quoted a fragment from a native work on grammar several centuries old, in which the pronunciation of the supposed silent letters is carefully described. Since then the problem has been disentangled; and now minor points only remain to be cleared up. Jaeschke devoted special attention to the dialectical sounds, and showed in several papers and by the comparative table prefixed to his dictionary that in the western and eastern dialects these sounds correspond more or less closely to the written forms. Thus the valuable testimony of these dialects may be added to the evidence furnished by foreign transcriptions of Tibetan words, loan words in conterminous languages, and words of common descent in kindred tongues. And the whole shows plainly that the written forms of words which are not of later remodelling are really the representatives of the pronunciation of the language as it was spoken at the time of the transcription. The concurrence of the evidence indicated above enables us to form the following outline of the evolution of Tibetan. In the 7th century there was no difference between the spoken and the written language. Soon afterwards, when the language was extended to the western valleys, the prefixed and most of the important consonants vanished from the spoken words. The *ya-tag* and *ra-tag* or *y* and *r* subscript, and the *s* after vowels and consonants, were still in force. The next change took place in the central provinces; the ra-tags were altered into cerebral dentals, and the ya-tags became č. Later on the superscribed letters and finals *d* and *s* disappeared, except in the east and west. It was at this stage that the language spread in Lahul and Spiti, where the superscribed letters were silent, the *d* and *g* finals were hardly heard, and *as*, *os*, *us*, were *ai*, *oi*, *ui*. The words introduced from Tibet into the border languages at that time differ greatly from those introduced at an earlier period. The other changes are more recent and restricted to the provinces of U and Tsáng. The vowel sounds *ai*, *oi*, *ui*, have become *ē*, *ō*, *ū*; and *a*, *o*, *u*, before the finals *d* and *n* are now ä, ö, ü. The *mediæ* have become aspirate tenues with a low intonation, which also marks the words having a simple initial consonant; while the former aspirates and the complex initials simplified in speech are uttered with a high tone, or, as the Tibetans say, "with a woman's voice," shrill and rapidly. An inhabitant of Lhása, for example, finds the distinction between *sh* and *zh*, or between *s* and *z*, not in the consonant, but in the tone, pronouncing *sh* and *s* with a high note and *zh* and *z* with a low one. The introduction of the important compensation of tones to balance phonetic losses had begun several centuries before, as appears from a Tibetan MS. (No. 462*b* St. Petersburg) partly published by Jaeschke *Monatsber. Akad. Berl.*, 1867). A few instances will serve to illustrate what has been said. In the bilingual inscriptions, Tibetan and Chinese, set up at Lhása in 822, and published by Bushell in 1880, we remark that the silent letters were pronounced: Tib. *spudgyal*, now *pugyal*, is rendered *suh-pot-ye* in Chinese symbols; *khri*, now *t'i*, is *kieh-li*; *hbrong* is *puh-lung*; *snyan* is *sheh-njoh* and *su-njoh*; *srong* is *su-lun*, *su-lung*, and *si-lung*. These transcriptions show by their variety that they were made from the spoken and not from the written forms, and, considering the limited capacities of Chinese orthoepy, were the nearest attempt at rendering the Tibetan sounds. *Spra* or *spreu* (a monkey), now altered into *ḍeu* at Lhása, *ṭeu* in Lahul, Spiti, and Tsáng, is still more recognizable in the Gyarung *shepri*, and in the following degenerated forms—*shreu* in Ladak, *streu-go* in Khams and in cognate languages, *soba* in Limbu, *saheu* in Lepcha, *simai* in Tablung Naga, *sibeh* in Abor-Mira, *shibe* in Sibsagar Miri, *sarrha* in Kol, *sara* in Kuri, etc. *Grog*-ma (ant), now altered into the spoken *t'oma*, is still *kyoma* in Bhutan, and, without the suffix, *korok* in Gyarung, *k'oro-* in Sokpa, *k'orok*, *k'alek* in Kiranti, etc. *Grang*-po (cold), spoken *t'ammo*, is still *grang*-mo in Takpa, *k'yam* in Burmese, etc. A respectful word for "head" is *u*, written *dbu*, which finds its cognates in Murmi *thobo*, Kusunda *chipi*, Sibsagar Mira *-tuh*, etc. *Byu* (bird), spoken *chya*, is still *pye* in Gyarung. *Brjod* (to speak), pronounced *jod*, is cognate to the Burmese *pyauhtso*, the Garo *brot*, etc. The word for "cowries" is *'gron-* in written, *rum-* in spoken Tibetan, and *grwa* in written Burmese; *slop* (to learn), spoken *lop*, is *slop* in Melam. "Moon" is *zlava* in written and *dawa* in spoken language, in which *-va* is a suffix; the word itself is *zla-*, cognate to the Mongol *ssara*, Sokpa *sara*, Gyarung, *t-sile*, Vayu *cholo*, etc. The common spoken word for "head" is *go*, written *mgo*, to which the Munipuri *moko* and the Mishmi *mkura* are related. Sometimes the written forms correspond to double words which have disappeared. For instance, *gye* (eight), which is written *brgyad* and still spoken *vrgyad* in Balti in the west and Khams in the east, is *gyad* in Ladak, Lahul, and U. The same word does not appear elsewhere; but we find its two parts separately, such as Gurung *pre*, Murmi *pre* Taksya *phre*, and Takpa *gyet*, Serpa *gye*, Garo *chet*, etc. *Rta* (horse) is reduced to *ta* in speech, but we find *ri*, *rhyi*. *roh* in Sokpa, Horpa, Thochu, Miniak, and *tá*, *tah*, *teh*, *t'ay* in Lhopa, Serpa, Murmi, Kami, Takpa, etc., both with the same meaning. Such are the various pieces of evidence obtained from an endless number of instances. The cases referred to above do not, owing to the difference of the causes, yield to any explanation of this kind. And it must be admitted that there are also many cases, some of them caused by irregularities of writing, modification of spelling by decay, and by a probable use of prefixes, still unascertained, which also resist explanation, though the account just given stands good whatever solution the question of prefixes may receive in future.

Literature.

Little is known of the non-religious literature of Tibet. The most popular and widely circulated book is called *The Hundred Thousand Songs of the Venerable Milaraspa*. Their author Milaraspa (unless the work should be attributed to his disciples), often called Mila, was a Buddhist ascetic of the 11th century; according to Jaeschke, during the intervals of meditation he travelled through the southern part of middle Tibet as a mendicant friar, instructing the people by his improvisations in poetry and song, proselytizing, refuting and converting heretics, and working manifold miracles. His legends are not without wit and poetical merit. A number of poems written in an elevated and special style, dramatic works, and collections of fairy tales and fables are said to be in existence. A very extensive work, the *Djrung yg* (Sgruns yg), regarded as the national epic in Khám, has been partly seen by Desgodins and Baber. It is in prose; but the dialogue, interspersed with songs, is metrical, and is much more extensive than the prose framework. Religious discussions and philosophical dissertations alternate with comic episodes. It includes three divisions,—the *Djiung ling*, which describes the invasion of part of Tibet by the Djiung or Moso; the *Hor ling*, which recounts the conquest of the Hor (Turk tribes) by the Tibetans, and conveys much historical information in a tale of magic and marvel; and the *Djia ling* (Chinese division), which narrates a contest of unknown date between the Tibetans and the Chinese. This work has apparently never been published, and even the manuscripts of the three divisions cannot, says Baber, be obtained in a complete form. But every Tibetan, or at least every native of Khám, who possesses any education, is able to recite or to chant passages of great length. Another Tibetan epic, the *Gyaldrung*, praises Dagyolong, a famous warrior who subdued the savage men of Khám. Besides these poems we find allusions to a *sgrung*, referring to the Yesser Khan. Dramatic works exist, as well as translations of Galen, also of the *Ramayana* in the first vol. of the *Bstodts'ogs* of the *Bstan-hgyur*. For the religious literature, which is considerable, see LĀMĀISM.

Writing.

Writing was not introduced until the 7th century. Notched sticks (*shing-chram*) and knotted cords were in current use, but the latter contrivance is only faintly alluded to in the Tibetan records, while of the other there are numerous examples. No mention is anywhere made of a hieroglyphical writing, but on the eastern frontier the medicine-men or *tomba* of the Moso have a peculiarly pictorial writing, which is known in Europe from two published MSS. (in *Journ. Roy. As. Soc.*, 1885, vol. xvii.); though apparently now confined solely to purposes of witchcraft, it perhaps contains survivals of a former extensive system superseded by the alphabetic writing introduced from India. According to tradition—a tradition of which the details are open to criticism—the alphabet was introduced from India by Tonmi Samb'ota, who was sent to India in 632 by King Srong btsan to study the Sanskrit language and Buddhist literature. Tonmi Samb'ota introduced the so-called "writing in thirty characters" (six of which do not exist in Sanskrit) in two styles,—the "thick letters" or "letters with heads," now commonly used in printed books, and the half-cursive "cornered letters," so called from their less regular heads. The former are traditionally said to have been derived from the Landza character. The Landza of Nepal, however, is certainly not the origin of the Tibetan letter, but rather an ornamental development of the parent letter. The close resemblance of the Tibetan characters "with heads" to the Gupta inscriptions of Allahabad shows them to have been derived from the monumental writing of the period; and various arguments appear to show that the other Tibetan letter came from the same Indian character in the style in which it was used in common life. The Tibetan half-cursive was further developed into the more current "headless" characters of which there are several styles. From the monumental writing of Tibet was derived, for the special use of the Mongols in the 13th century, the short-lived writing known as Bagspa, from the name of the lama who worked it out.

Bibliography.—The works of Csoma de Körös, Alex. Cunningham, Sarat Chandra Das, Desgodins, Léon Feer, Éd. Foucaux, A. A. Georgi, Bryan H Hodgson, H. A. Jaeschke, Th. H. Lewin, Max Müller, A. Rémusat, W. Robinson, J. J. Schmidt, F. C. G. Schroeter, and A. Schiefner have been already mentioned, and those of J. W. Bushell, A. Campbell, T. W. Rhys Davids, Huc and Gabet, Koeppen, C. Markham, Pallas, Ssanang Ssetsen, Schott, Pundit Nain Singh, and others are referred to under LĀMĀISM, LADAK and BALTI, and LHASA (*qq.v.*). The following also may be named: E. Colborne Baber, "Travels and Researches in Western China," in *Roy. Geogr. Soc. Suppl. Papers*, I., 1882; C. H. Desgodins, *Le Thibet d'après la correspondance des Missionaires*, Paris, 1885; Th. Duka, *Life and Works of Alexander Csoma de Körös*, London, 1885; Konrad Ganzenmüller, *Tibet*, Stuttgart, 1878; Krick, *Relation d'un Voyage au Thibet en* 1852, Paris, 1854; A. Krishna, *Explorations in Great Tibet and Mongolia*, made in 1879-82; *Report* prepared by J. B. N. Hennessey, Dehra Dun, 1884, fol.; Terrien de Lacouperie, "Beginnings of Writing in and around Tibet," in *Journ. Roy. As. Soc.*, 1885, xvii.; Id., *The Languages of China before the Chinese*, London, 1887; J. R. Logan, in *Journal of the Indian Archipelago Eastern Asia*, vol. vi., Singapore, 1852; W. Woodville Rockill, "The Early History of Bod-yul," append. to *The Life of the Buddha*, from Tibetan sources, London, 1884: Em. von. Soc.*, 1877, vol. xlvii.; H. Yule, *The Book of Ser Marco Polo*, 2d ed., London, 1874. (T. DE L.)

TIBULLUS, ALBIUS (*c.* 54–19 B.C.), was the second in the tetrad of the elegiac poets of Rome. As we learn from Ovid, he was the successor of Cornelius Gallus and the immediate predecessor of Propertius. The information which we possess about him is extremely meagre. Besides the poems themselves—that is to say, the first and second books—we have only a few references in later authors and a short *Life* of probable but not undoubted genuineness. We do not know his prænomen; and his birthplace is uncertain. It is, however, a plausible conjecture that he came from Gabii. The year of his birth has been variously assigned; but 54 B.C. may be taken as approximately correct. This would make him about twenty-five when he accompanied Messala on his Aquitanian campaign in 29, and thirty-five at his untimely death in 19. His station was that of a Roman knight; and he had inherited a very considerable estate. But, like Virgil, Horace, and Propertius, he seems to have lost the greater part of it in 41 amongst the confiscations which Antony and Octavian found expedient to satisfy the rapacity of their victorious soldiery. Tibullus, like Propertius, seems to have lost his father early. He once mentions his mother and sister; and, according to Ovid's elegy upon him, they were alive at his death.

Tibullus's chief friend and patron was M. Valerius Messala Corvinus, himself an orator and poet as well as a statesman and commander. Messala, like Mæcenas, was the centre of a literary circle in Rome; but the bond between its members was that of literature alone. They stood in no relations to the court; and the name of Augustus is never once to be found in the writings of Tibullus. It was doubtless this community of taste which gained the young poet the friendly notice of Messala, who offered him an honorable position on his private staff when he was dispatched at the end of 30 by Augustus to quell the Aquitanian revolt. Tibullus distinguished himself in the campaign and was decorated for his services. But this did not rouse in him any military ardor. His tastes lay in quite other directions; and he always speaks of war with horror and dislike. At the end of the war in 29 Tibullus returned to Rome, and thenceforward his life seems to have been divided between Rome and his country estate, though his own preferences were altogether for the country life. Soon after his return he made the acquaintance of his first love, Delia. This is what he calls her in his poems; but we learn from Apuleius that her real name was Plania. Delia seems to have been a woman of middle station. It is impossible to give an exact account of the intimacy. The poems which refer to her are arranged in no chronological order. She appears now as single, now as married; but we do not hear anything either of her marriage or of her husband's death. It is clear, however, that it was the absence of her husband on military service in Cilicia which gave Tibullus the opportunity of making or renewing the acquaintance. It was not dropped when he returned, probably with Messala in 27. It was not a difficult task to deceive the simple soldier; and Delia was an apt pupil in the school of deception,—too apt, as Tibullus saw with dismay when he found that he was not the only lover. His entreaties and appeals were of no avail; and after the first book we hear no more of Delia. It was during the earlier period of this attachment and probably in the spring of 28 that, yielding to his friend's earnest and repeated requests, Tibullus left Delia to accompany Messala on a mission to Asia. He fell ill, however, and could not get farther than Corcyra. In the second book the place of Delia is taken by Nemesis, which is also a fictitious name. Nemesis (like the Cynthia of Propertius) was a courtesan of the higher class; and she had other admirers besides Tibullus. He complains bitterly of his bondage, and of her rapacity and hardheartedness. In spite of all, however, she seems to have retained her hold on him until his death. Tibullus died prematurely, probably in 19, and almost immediately after Virgil, in order, as their contemporary Domitius Marsus pathetically puts it,

> "That none might sing of gentle love in elegy's sad lay,
> Or gallant march of royal war on epic feet essay."

The character of Tibullus is reflected in his poems. Though not an admirable it is certainly an amiable one. He was a man of generous impulses and a gentle unselfish disposition. He was loyal to his friends to the verge of self-sacrifice, as is shown by his leaving Delia to accompany Messala to Asia, and constant to his mistresses with a constancy but ill deserved. His tenderness towards them is enhanced by a refinement and delicacy of feeling which are very rare amongst the ancients. Horace and the rest taunt the cruel fair with the retribution that is coming with the years, when they will exult over the decay of the once imperious beauty. If Tibullus refers to such a fate, he does it by way of warning and not in any petty spirit of triumph or revenge. Cruelly though he may have been treated by his love, he does not invoke curses upon her head. He goes to her little sister's grave, hung so often with his garlands and wet with his tears, and bemoans his fate to the dumb ashes there. Tibullus has no leanings to an active life: his ideal is a quiet retirement in the country with the loved one at his side. He has no ambition and not even the poet's yearning for immortality. His muse may go packing if it cannot propitiate the fair. As Tibullus loved the country life, its round of simple duties and innocent recreations, so he clung to its faiths, and in an age of crude materialism and the grossest superstition he was religious in the old Roman way. A simple, gentle, affectionate nature such as his could not fail to win esteem; and his early death caused deep regret in Rome. Tibullus was remarkable, his biographer tells us, for his good looks and the care that he bestowed upon his person. As a poet he reminds us in many respects of the English Collins. His clear, finished, and yet unaffected style made him a great favorite with his countrymen, and placed him, in the judgment of Quintilian, at the head of their elegiac writers. And certainly within his own range he has no Roman rival. For natural grace and tenderness, for exquisiteness of feeling and expression, he stands alone. He has far fewer faults than Propertius, and in particular he never overloads his lines with Alexandrian learning. But, for all that, his range is limited; and in power and compass of imagination, in vigor and originality of conception, in richness and variety of poetical treatment, he is much his inferior. The same differences are perceptible in the way the two poets handle their metre. Tibullus is smoother and more musical but liable to become monotonous; Propertius, with occasional harshnesses, is more vigorous and varied. It need only be added that in many of Tibullus's poems a symmetrical composition is obvious, although the symmetry must never be reduced to a fixed and unelastic scheme.

It is probable that we have lost some of the genuine poems of Tibullus. On the other hand, much has come down to us under his name which must certainly be assigned to others. Only the first and second books of the usual order, or about 1240 verses, can claim his authorship. The first book consists of poems written at various times between 30 and 26. It was probably published about 25 or 24. The second book seems to have been a posthumous publication. It is very short, containing only 428 verses, and is evidently incomplete. In both books occur poems which give evidence of internal disorder; but scholars cannot agree upon the remedies to be applied.

The third book, which contains 290 verses, is by a much inferior hand. The writer calls himself Lygdamus and the fair that he sings of Neæra. He was born in the same year as Ovid, in the consulship of Hirtius and Pansa; but there is nothing Ovidian about his work. He has very little poetical power, and his style is meagre and jejune. He has a good many reminiscences and imitations of Tibullus and Propertius; and they are not always happy. The separation of the fourth book from the third has no ancient authority. They form one in the best MSS., and are quoted as one in the anthologies of the Middle Ages. The division dates from the revival of letters, and is due to the Italian scholars of the 15th century. The fourth book consists of poems of very different quality. The first is a composition in 211 hexameters on the achievements of Messala; and very poor stuff it is. The author is unknown; but he was certainly not Tibullus. The poem itself was written in 31, the year of Messala's consulship. The next eleven poems relate to the loves of Sulpicia and Cerinthus. Sulpicia was a Roman lady of high station and the daughter of Valeria, Messala's sister. She had fallen violently in love with Cerinthus, about whom we know nothing but what the poet tells us; and he soon reciprocated her feelings. The Sulpicia elegies divide into two groups. The first comprises iv. 2–6, containing ninety-four lines, in which the theme of the attachment is worked up into four graceful poems composed for Sulpicia and Cerinthus alternately. The second, iv. 8–12 (to which seven should be added), consists of Sulpicia's own letters. They are very short, only forty lines in all; but they have a quite unique interest as being the only love poems by a Roman woman that have escaped the ravages of time. Their frank and passionate outpourings remind us of Catullus. The style and metrical handling betray the novice in poetical writing; and the Latinity is "feminine." The thirteenth poem (twenty-four lines) claims to be by Tibullus; but it is a miserable forgery. It is little more than a cento from Tibullus and Propertius. The fourteenth is a little epigram of four lines. There is nothing to determine its authorship. Last of all comes the epigram of Domitius Marsus already referred to. To sum up: the third and fourth books appear in the oldest tradition as a single book; if separated, they would contain only 290 and 373 lines respectively, as against 812 of the first book and 428 of the incomplete second; and they comprise pieces by different authors and in very different styles, none of which can be assigned to Tibullus with any certainty. The natural conclusion of this is that we have here a collection of scattered compositions relating to Messala and the members of his circle which has been added as an appendix to the genuine relics of Tibullus. When this collection was made cannot be exactly determined; but it was certainly not till after the death of Tibullus, and probably not till after Messala's. Besides the foregoing, two pieces in the collection called *Priapea* have been attributed to Tibullus; but there is very little external and no internal evidence of his authorship. The text of Tibullus is, on the whole, better preserved than that of Catullus, and still more so than that of Propertius. But it still contains many corruptions and several lacunæ, besides the disarrangements already referred to.

The value of the short *Vita Tibulli*, which is found at the end of the Ambrosian and Vatican, also of inferior, MSS., has been much discussed. E. Baehrens maintains that it is genuine, and possibly an abstract from the book of Suetonius, *De Poetis*,—a conjecture supported by the fact that even in so short a piece of writing more than one Suetonian phrase occurs (Baehr., *Tibullische Blätt.*, p. 4 *sq.*),—while Schulze (*Ztschr. f. d. Gymnasialwesen*, Berlin, xxxii. 658) regards it as a mere *rifacimento* of Horace, *Ep.*, i. 4, and various passages in Tibullus. E. Hiller (*Rhein. Mus.*, xviii. 350) thinks it genuine, but assigns it to the late classical period,—a view quite consistent with an ultimate Suetonian origin. It is as follows: "Albius Tibullus, eques R. e Gabiis [Baehrens's ingenious conjecture for the MS. eques *regalis*, R. being the customary abbreviation for *Romanus*], insignis forma cultuque corporis observabilis, ante alios Corvinum Messalam ob ingenium [so Baehr., MSS. *originem*, others *oratorem*] dilexit cuius et contubernalis Aquitanico bello militaribus donis donatus est. Hic multorum iudicio principem inter elegiographos optinet locum. Epistulæ quoque eius, quamquam breves, omnino utiles sunt [so the MSS.; Baehrens reads *subtiles*. The letters referred to are Sulpicia's]. Obiit adulescens, ut indicat epigramma superscriptum" (*i.e.*, the one ascribed to Domitius Marsus. These words seem to be a later addition to the *Life*). Another moot question of some importance is whether our poet should be identified with the Albius of Horace (*Od.*, i. 33; *Epist.*, i. 4), as is done by the commentator Porphyrio (200–250 A.D.) in his *Scholia*. In the former passage Horace tells Albius to moderate his grief at the cruelty of Glycera, nor to descant in piteous elegies on her broken faith and the victory of a younger rival. It is clear that Glycera cannot be Nemesis; for it is a pseudonym, as the context shows, and Horace would, of course, have used the same pseudonym as Tibullus. If, on the other hand, Nemesis were a real name, Horace had no occasion to use a pseudonym. It is possible that Tibullus had another mistress, Glycera, of whom we know nothing further, and that the *miserabiles elegi* have perished; but this is a mere supposition. The Albius of the epistle has an estate at Pedum, where Horace conjectures he may be musing or writing. He is handsome, rich, and knows how to enjoy life. He is wise and has the gift of speech, popularity, reputation, and good health *abunde*,—an enviable list of attributes, but certainly one, which does not agree very well with what we know from elsewhere of Tibullus. The theory, then, that these passages refer to Albius Tibullus must be pronounced, with Baehrens, unproven; and the *forma* of Horace's Albius must not be used, as Schulze uses it, to subvert the credit of the *insignis forma* of the *Life*.—Ovid, *Trist.*, iv. 10, 53 *sq.*, "successor fuit hic [Tibullus] tiba, Galle, Propertius, illi, quartus ab his serie temporis ipse fui." In the preceding couplet he had said, "Vergilium vidi tantum nec amara Tibullo tempus amicitiæ fata dedere meæ." Ovid, who was born in 43, would be only twenty-four at Tibullus's death if it occurred in 19.—The loss of Tibullus's landed property is attested by himself (i. 1, 19 *sq.*), "Vos quoque felicis quondam, nunc pauperis agri custodes, fertis munera vestra, Lares. Tunc vitula innumeros lustrabat cæsa iuvencos; nunc agna exigui est hostia parva soli" (comp. 41, 42). Its cause is only an inference, though a very probable one. That he was allowed to retain a portion of his estate with the family mansion is clear from ii. 4, 53, "Quin etiam sedes iubeat si vendere avitas, ite sub imperium sub titulumque, Lares." Compare the passages quoted above and i. 1, 77, 78.—Messala composed epigrams (Plin., *Ep.*, v. 3) and bucolic poems (comp. the pseudo-Virgilian *Catalepton*, ii.); but he was more conspicuous as a patron than as a poet. On his circle and that of Mæcenas, see Teuffel, *Gesch. der römischen Literatur*, 4th ed., p. 431 (vol. i. p. 389 of the Eng. transl.). Other members of the circle were Messala's brother, Pedius, Publicola, Æmilius Macer (probably the Macer addressed in ii. 6), Valgius Rufus, Lygdamus, Sulpicia, and others, and even Ovid to a certain extent (Ov., *Pont.*, i. 7, 28 *sq.*; *Trist.*, iv. 4, 27 *sq.*). Tibullus was Messala's *contubernalis* in the Aquitanian war (*Vita Tib.* and Tib., i. 7, 9 *sq.*, a poem composed for Messala's triumph). It should be stated that the date of the Aquitanian campaign is still undetermined. It has been assigned to 30, 29, and 28. He received *militaria dona* (*Vita*); Baehrens unkindly suggests it was for purely poetical services (*Tib. Bl.*, p. 15). Tibullus's dislike of war is always coming to the surface (*e.g.* i., 3; i. 10), and so also his love of quiet and retirement (i. 1; ii. 1; 3, 1 *sq.*)—Apuleius (*Apol.*, 10), "accusent Tibullum . . . quod ei sit Plania in animo, Delia in versu;" this is the most probable form of the name, Delia (δῆλος) being a translation of Plania. As regards her station, it should be noticed that she was not entitled to wear the *stola*, the dress of Roman matrons (i. 6, 68). Her husband is mentioned as absent (i. 2, 67 *sq.*). She eludes the custodes placed over her (i. 2, 15, and 6, 7). Tibullus's suit was favored by Delia's mother, of whom he speaks in very affectionate terms (i. 6, 57 *sq.*). For Tibullus's illness at Corcyra, see i. 3, 1 *sq.*, 55 *sq.* The fifth elegy was written during estrangement (*discidium*) and the sixth after the return of the husband and during Delia's double infidelity. On the difficulty of "harmonizing" the Delia elegies, see F. Leo (in Kiessling and Wilamowitz-Möllendorf's *Philol. Unters.*, ii. pp. 19–23), who is, however, too skeptical. Any other attachments that Tibullus formed (such as the supposed one for Glycera) must have fallen between the end of the Delia and the beginning of the Nemesis connection.—Ovid, writing at the time of Tibullus's death (*Am.*, iii. 9, 31), says—"Sic Nemesis longum, sic Delia, nomen habebunt, altera cura recens, altera primus amor." Nemesis is the subject of book ii. 3, 4, 6. The mention of a *lena* (ii. 6 settles her position. The connection had lasted a year when ii. 5 was written (see ver. 109). It is worth noticing that Martial selects Nemesis as the source of Tibullus's reputation, "fama est arguti Nemesis lasciva Tibulli" (*Epigr.*, viii. 73, 7); compare xiv. 193, "usit amatorem Nemesis lasciva Tibullum, in tota iuvit quem nihil esse domo," where, however, the second line is taken from one of the Delia elegies. Ovid, *Amores*, iii. 9, 58, "me tenuit moriens deficiente manu." The point of this can only be seen by reference to Tib., i. 1, 60, where Delia is addressed, "te teneam moriens deficiente manu."—The epigram of Domitius Marsus on his death is as follows: "Te quoque, Vergilio comitem, non æqua, Tibulle, mors iuvenem campos misit ad Elysios, ne foret aut elegis molles qui fleret amores aut caneret forti regia bella pede."—Tibullus condemns the rough handling which the inamorata often suffered from her Roman lover, *e.g.*, i. 10, 59–60—"A! lapis est ferrumque, suam quicumque puellam verberat; e caelo deripit ille deos." The tenderness of the passage paraphrased above (ii. 6, 41) is perhaps unmatched in ancient poetry: "desino, ne dominæ luctus renoventur acerbi. Non ego sum tanti ploret ut illa semel." —His love for a rustic life and rustic worship appears throughout whole poems, as in i. 1 and ii. 1, 2. Of his poetry he says (ii. 4, 19), "Ad dominam faciles aditus per carmina quæro; ite procul, Musæ, si nihil ista valent."—Specimens of Tibullus at his best may be found in i. 1, 3, 89–94; 5, 19–36; 9, 45–68; ii. 6. Quintilian says (*Inst.*, x. 1, 93), "Elegia quoque Græcos provocamus, cuius mihi tersus atque elegans maxime videtur auctor Tibullus; sunt qui Propertium malint; Ovidius utroque lascivior sicut durior Gallus."—Ovid (*Am.*, *l.c.*) well calls him *cultus*, Martial *argutus*, fine-toned." A short but not inadequate account of Tibullus's prosody is given by L. Mueller in his introduction to Tibullus (*Catullus, Tibullus, und Propertius*, Leipsic, 1880). Catullus and Tibullus lengthen a short vowel before *sp* and *fr*; Propertius always keeps it short in similar conjuctions, even where *s* is followed by two consonants, as in *striges*. Catullus, and in three cases Tibullus, allow a trisyllabic verb to close the pentameter. Propertius never permits himself this liberty, although in his earlier poems he has as many trisyllabic endings as Tibullus—The chronology of the first book is discussed amongst others by Baehrens (*Tib. Bl.*, pp. 12–24). But the data do not admit in all cases of his precise determinations. Baehrens and Hiller (*Hermes*, xviii. 353) agree that the second book was posthumous. If it had been known to Ovid when he wrote his elegy on the poet's death, it seems certain that he would have quoted from it. Hiller assigns 2 B.C. as an inferior limit, by which time Ov., *Ars Am.*, iii. 3, 535 *sq.*, must have been written. Amongst the "disarranged poems" are i. 1, 4, 6 and ii. 3, 5. Proposed rearrangements of them may be found in Hiller's *Tibullus* (1885). Charisius (pp. 66 and 105) quotes part of a hexameter which is not found in the extant poems of Tibullus.

The Tibullian authorship of book iii. has long ago been surrendered by scholars. Its latest defenders have been Fuss (*De Elegg. Libro quem Lygdami esse putant*, Münster, 1867) and the English translator, J. Cranstoun. It has been suggested that *Lygdamus* (λύγδος, white marble) is a Grecizing of *Albius*, some relation of Tibullus (compare Hiller, *Hermes*, xviii. 353, n. 2); and this is possible. Gruppe's long-exploded theory that Ovid was the author has been recently revived by J. Kleeman (*De Libri III. Carminibus quæ Tibulli Nomine circumferuntur*, Strasburg, 1876). Considerable difficulty is caused by iii. 5, 15–20, which contains agreements with three passages of Ovid, *Ars Am.*, ii. 669 *sq.*; *Tr.*, iv. 10, 6: "cum cecidit fato consul uterque pari" (Lygdamus and Ovid using word for word the same expression for the year of their birth, the consulship of Hirtius and Pansa); and *Am.*, xi. 14, 23 *sq.*, which are much too close to be accidental, and in which the theory that Ovid was the imitator is excluded by the fact that the lines are much more appropriate to their surroundings in Ovid than in Lygdamus. In consequence Baehrens (*Tib. Bl.*, 40) regards the poem as written after 13 A.D., the date of the *Tristia*, while Hiller (*l.c.*, p. 359) regards the lines as a later addition by Lygdamus himself. In either case it would be published after 13. The line quoted above may have obtained proverbial currency before either of the passages was written, as the death of both consuls in one year would have impressed the Roman imagination as powerfully as the coincident deaths of Adams and Jefferson did the American. In that case no part of book iii. need be later than the Christian era. For Lygdamus's imitations of Tibullus, see Gruppe, *Die römische Elegie*, i. 112 *sq.* There are resemblances between the pseudo-Tibullus and the *Catalepton* (Baehr., *op. cit.*, p. 52).—The view of Baehrens (*Tib. Blätt.*, 49) and others that iii. and iv. originally formed one book may now be considered established, in spite of Birt's objections (*Das antike Buchwesen*, 426 *sq.*); and Hiller in his edition prints them as one. They were published some time after book ii., probably after the death of Messala (Baehrens, *op. cit.*, 48, adds, "and of his son Messalinus"). Further determination of the date is impossible. We do not know when they were added to the genuine poems of Tibullus; but it was probably before the *Life* was written.—Most scholars since Lachmann *Kl. Schr.*, ii. 149) have condemned the "Panegyric on

Messala." It is an inflated and at the same time tasteless declamation, entirely devoid of poetical merit. The language is often absurdly exaggerated, *e.g.*, 190 *sq.* The author himself seems to be conscious of his own deficiencies (1 *sq.*, 177 *sq.*). All that we know about him is that he, like so many of his contemporaries, had been reduced to poverty by the loss of his estates (181 *sq.*). The date is fixed by 121 *sq.*—Sulpicia was the daughter of Servius Sulpicius (iv. 10, 4), and she seems to have been under the tutelage of Messala (cf. 14, 5-8), her uncle by marriage (Haupt, *Hermes*, iv. 33 *sq.*). Cerinthus is a real name. He was probably a Greek (Baehr., p. 41 and note). He is not to be identified with the Cornutus addressed in Tib., ii. 2, 3. Gruppe (*op. cit.*, 27) and Teuffel (*Studien*, 367) attribute iv. 2-6 to Tibullus himself; but the style is different, and it is best to answer the question as Baehrens does (p. 46) with a *non liquet.* For Sulpicia's style and its feminine Latinity, compare Gruppe (*op. cit.*, i. 49 *sq.*).—The direct ascription of iv. 13 (verse 13—"nunc licet e caelo mittatur amica Tibullo") to Tibullus probably led to its being included in the collection. Later on, it and the epigram together caused the addition of the pseudo-Tibulliana to the genuine works. Although not suspected till recently, it is unquestionably spurious; see the examination by Postgate (*Journ. of Phil.*, ix. 280 *sq.*).—The authorship of the two *Priapea* (one an epigram and the other a longer piece in iambics) is discussed by Hiller (*Hermes*, xviii. 343-9). His conclusions are that, as regards the iambics, the theory that Tibullus was its author, though from the nature of the case it does not admit of complete disproof, rests upon the slightest of foundations, and, as regards the epigram, that the hypothesis of a Tibullian authorship is quite inadmissible.

The text of Tibullus is in a much better condition than it was in Lachmann's time, thanks to the recent discovery of new MSS. by E. Baehrens. Of these the Ambrosianus (A), of date about 1374, and the Vaticanus (V), end of the 14th or beginning of the 15th century, agree so closely that they can be referred to an original extant in the early part of the 12th or 13th century but long since lost. A third is the Guelferbytanus (G), written in Lombard characters, but on parchment of the beginning of the 15th century. Baehrens, who attaches great importance to the original readings of this codex, considers it a faithful copy of a 10th or 11th century MS. Besides these we have a number of extracts from Tibullus in the *Florilegium Parisinum*, an anthology from various Latin writers which probably dates back to the 11th century, and which we have from two MSS. at Paris (7647 and 17,903); see Meyncke, *Rhein. Mus.*, xxv. 369 *sq.* Baehrens considers that these excerpta Parisina and G are closely connected, and that their original and that of A and V were both descended from a more ancient MS., which he calls O, but which was still full of corruptions. The so-called *Excerpta Frisingensia*, preserved in an 11th-century MS. (now at Munich), but unfortunately very few in number, are extracted from a much better MS. than O. Still better was the *Fragmentum Cuiacianum*, which we know only from Scaliger's collation (in the library at Leyden), and which is to be carefully distinguished from the codex Cuiacianus, a late MS. containing Catullus, Tibullus, and Propertius, and still extant. It only contained from iii. 4, 65 to the end. The codices which Lachmann used are later than all the foregoing and full of interpolations. Baehrens's estimate of the MS. authorities for Tibullus has not been accepted in all its details. In particular his high estimate of G has been disputed by Leo, *op. cit.*, p. 3; Rothstein, *De Tibulli Codicibus*, p. 67 *sq.* (who also endeavors to raise Lachmann's MSS. to an independent position again); and others. R. Leonhard, in a careful dissertation. *De Codicibus Tibullianis Capita Tria* (Munich, 1882), agrees with Baehrens in the main, though his pedigree of the MSS. (p. 53) is more elaborate.

Editions.—The first two editions of Tibullus and the pseudo-Tibulliana are that with Catullus, Propertius, and the *Silvæ* of Statius by Vindelin de Spira (Venice, 1472) and one of Tibullus separately by Florentius de Argentina, probably printed in the same year. Compare Huschke, *Tibullus*, Præf., vi. *sq.*, xxiii. *sq.* Amongst others we may mention those by Scaliger (with Catullus and Propertius, Paris, 1577, 1582, etc.), Broukhuys (Amsterdam, 1708), Vulpius (Padua, 1749), Heyne (Leipsic, 1817, 4th ed. by Wunderlich; with supplement by Dissen, 1819), Huschke (Leipsic, 1819, 2 vols.), Lachmann (Berlin, 1829, the first critical edition), Dissen (Göttingen, 1835). The most important edition with critical apparatus is that of E. Baehrens (Leipsic, 1878). The most recent edition, with critical introduction and index, is E. Hiller's (Leipsic, 1885). Recent texts are those of L. Mueller (Leipsic, 1880; also with Catullus and Propertius) and Haupt-Vahlen (Leipsic, 1885). There is no good recent commentary on Tibullus: we have to fall back on Heyne and Dissen. That by B. Fabricius (Berlin, 1881) does not even comprise all the poems. Some contributions are made to the subject in F. Leo's paper in Kiessling's and Wilamowitz Moellendorf's *Philol. Unters.*, ii. p. 3 *sq.*, and by J. Vahlen in the *Monatsberichte* of the Berlin Academy, 1878, pp. 343-356. For fuller bibliographies, see Engelmann's *Bibliotheca Scriptorum Latinorum* (ed. Preuss, 1882) and J. E. B. Mayor's *Bibliographical Clue to Latin Literature* (1875). For the older editions, see the preface to Huschke's. There is an excellent account of Tibullus in W. S. Teuffel's *Gesch. d. römisch. Literatur* (4th ed., L. Schwabe, 1882). Those in the Eng. tr. and Pauly's *Real-Encyklopädie* are antiquated. The following translations into English verse are known,—by Dart (London, 1720), Grainger (London, 1739, 2 vols., with Latin text and notes, subsequently reprinted), Cranstoun (Edinburgh and London, 1872). *An Essay towards a New Edition of the Elegies of Tibullus, with a Translation and Notes* (London, 1792), merely contains i. 1 and 7, 29-48. Sir C. A. Elton, *Specimens of the Classic Poets* (London, 1814, vol. xii. 141-171) contains i. 1; ii. 4; iii. 2-4; 6, 33 to end; iv. 2, 3. To these should probably be added *Tibullus, with other Translations from Ovid, Horace*, etc., by Richard Whiffin, London, 1829. Cranstoun's is the only complete version of merit; but it is far inferior to the translations by Elton, from whom Cranstoun seems sometimes to have borrowed. (J. P. P.)

TIBUR. See TIVOLI.

TIC DOULOUREUX. See NEURALGIA.

TICINO, or TESSIN, a canton of Switzerland, ranking as eighteenth in the Confederation, consists of the upper basin of the river from which it takes its name,—the Val Leventina, with the tributary valleys of Blegno and Maggia—and farther south takes in the districts of Lugano and Mendrisio between Lakes Maggiore and Como. Its total area is 1088.2 square miles, which is exceeded by only four other Swiss cantons,—Graubünden (Grisons), Bern, Valais, and Vaud. Of this 725.8 square miles are classed as productive, including 215.3 square miles covered by forests and 33.8 by vines; of the unproductive portion 24.3 square miles are occupied by lakes (most of that of Lugano belonging to the canton) and 13.1 by glaciers. The highest points in the canton are the Basodine (10,749 feet) in the northwest and the Valrhein (11,148 feet) in the northeast corners. In 1880 the population was 130,777 (the females exceeding the males by 10,000, doubtless owing to the emigration of the latter), being an increase of 11,158 on that of 1870; the increase was particularly marked in the Val Leventina and is due to the influence of the St. Gotthard Railway, which traverses the entire canton. Of this population 129,409 speak Italian; 342 of the remainder form the German-speaking hamlet of Bosco or Gurin in the Val Caverna (in northwest), a colony from the neighboring valley of Formazza or Pommat, which is politically Italian. In religion 130,017 are Roman Catholics. Until 1859 Ticino was partly (Val Leventina, Val Blegno, and the Riviera) in the metropolitan diocese of Milan, chiefly in that of Como, and is still practically (though not legally) administered by these two bishops,—all attempts made hitherto to incorporate them with the see of Chur or to secure the erection of a special see for them having failed. The chief towns are Lugano (6129 inhabitants), Airolo (3674), Mendrisio (2749), Locarno (2645), and Bellinzona (2436). Formerly Lugano, Locarno, and Bellinzona were the capital by turns of six years each; but since 1881 the seat of government has been permanently fixed at Bellinzona. Ticino stands in a comparatively low position as regards moral, educational, agricultural, and commercial matters. It has produced a number of sculptors, painters, and architects. Many of the men migrate during the summer in search of work as picture-dealers, waiters in cafés, chimney-sweeps, and especially as masons, plasterers, laborers, and navvies. A large quantity of fruit is grown; the chief articles exported are cattle, hay, fish, chestnuts, and earthenware. In manners, customs, and general character the inhabitants strongly resemble their Italian neighbors.

The canton is made up of all the permanent conquests (with one or two trifling exceptions) made by different members of the Swiss League south of the main chain of the Alps. From an historical point of view Italian Switzerland falls into three groups: (1) Val Leventina, conquered by Uri in 1440 (previously held from 1403 to 1426); (2) Bellinzona, the Riviera, and Val Blegno (held from 1419 to 1426), won in 1500 from the duke of Milan by men from Uri, Schwyz, and Nidwald, and confirmed by Louis XII. of France in 1503; (3) Locarno, Val Maggia, Lugano, and Mendrisio, seized in 1512 by the Confederates when fighting for the Holy League against France, ruled by the twelve members then in the League, and confirmed by Francis I. in the treaty of 1516. These districts were governed by bailiffs holding office two years and purchasing it from the members of the League; each member of group 3 sent annually an envoy, who conjointly constituted the supreme appeal in all matters. This government was very harsh and is one of the darkest pages in Swiss history. Yet only one open revolt is recorded—that of the Leventina against Uri in 1755. In 1798 the people were distracted by the Swiss and "Cisalpine republic" parties, but sided with the Swiss. On being freed from their hated masters, they were formed into two cantons of the Helvetic republic—Bellinzona (=1 and 2 above) and Lugano (=3). In 1803 all these districts were formed into one canton—Ticino—which became a full member of the Swiss Confederation. From 1810 to 1813 it was occupied by the troops of Napoleon. The roads over the Bernardino (1819-23) and the St. Gotthard (1820-30) were made under the constitution of 1814. But many of the old troubles reappeared and were only done away with by the constitution of 23d July, 1830, which (with subsequent modifications) prevails at the present time. A legislative assembly (112 members) chosen by direct election and an executive (5 members) chosen by the legislature are its principal features. The "optional referendum" (permitting the submission of any law to a popular vote if asked for by a certain number of citizens) was adopted in 1883. In 1848, on religious grounds and owing to fears as to customs duties, the canton voted in the minority against the Federal constitution of that year; but in 1874, though the people voted against the revised constitution, the legislature adopted it, and the canton was counted as one of the majority. Since 1830 the local history of the canton has been very disturbed owing to the fact that, though Roman Catholicism is the state religion, and all the population are Roman Catholic (the few Protestants having been expelled from Locarno in 1555), they are divided between the Radical and Ultramontane parties. Since 1876 the intervention of Federal troops (already known in 1870) has been quite common in consequence of conflicts of the local authorities *inter se*, or against the Federal assembly.

See *Der Kanton Tessin*, by Stefano Franscini (St. Gall, 1835).

TICK. See MITE.

TICKELL, THOMAS (1686–1740), English man of letters, the son of a clergyman, was born at Bridekirk, near Carlisle, in 1686. After a good preliminary education he went to Queen's College, Oxford, where in 1708 he took his degree, and of which college he was two years later elected fellow. He did not take orders, but by a dispensation from the crown was allowed to retain his fellowship until his marriage in 1726. As a poet Tickell displayed very mediocre qualities. His success in literature, as in life, was mainly due to the friendship and patronage of Addison, who procured for him (1717) the under secretaryship of state, to the chagrin of Steele, who thenceforth bore Tickell no good will. During the peace negotiations with France Tickell published the *Prospect of Peace*, which was well spoken of in the *Spectator* and reached a sixth edition. In 1717 he brought out a translation of the first book of the *Iliad* contemporaneously with Pope's version. *Kensington Gardens*, his longest poem, which appeared in 1722, is inflated and pedantic, and was doomed to oblivion from its birth. Dr. Johnson's criticism of it gives it its due meed of praise and blame. The most popular of Tickell's poetical writings was the ballad of "Colin and Lucy," which will bear comparison with some of the ballad poems of Wordsworth. Whether from fear of Pope's rivalry or from unbiassed choice, Tickell abandoned the translation of the *Iliad* and set about rendering the *Odyssey* and Lucan into English. In 1725 he was appointed secretary to the lords justices of Ireland,—a post which he retained until his death, which took place at Bath on 23d April, 1740. Tickel rose once above the level of mediocrity, when he wrote his elegy addressed to the earl of Warwick on the death of Addison. Posterity has endorsed Dr. Johnson's affirmation that this elegy is equal in sublimity and elegance to any funeral poem which had theretofore appeared,—and this notwithstanding Steele's caustic disparagement, that it was only "prose in rhyme." Tickell also contributed to the *Spectator* and the *Guardian*.

See "T. Tickell," in Johnson's *Lives of the Poets*; the *Spectator*; Anderson's *English Poets*; Ward's *English Poets*.

TICKNOR, GEORGE (1791–1871), historian of Spanish literature, was born at Boston (Mass.) on 1st August, 1791. He received his early education from his father, Elisha Ticknor, who, though at that time in business, had been principal of the local Franklin public school and was the originator both of the system of free primary schools in Boston and of the first New England savings-bank. He studied at Dartmouth College from 1805 to 1807, and on leaving it was placed for nearly three years under Dr. Gardiner, a pupil of Dr. Parr. In the autumn of 1810 Ticknor entered the office of a leading Massachusetts lawyer, and, though his studies appear to have been literary rather than legal, he was admitted to the bar in 1813. He at once commenced practice; but a year's experiment convinced him that scholarship and letters would be more congenial to his abilities. In the spring of 1815 he set sail for England. Attractive in appearance, cultured, vivacious, and sympathetic, he had won many influential friends in America, and his introductions gave him access to most of the men then worth knowing in Europe. He spent nearly two years at Göttingen; but he also visited the chief towns on the Continent, meeting Prescott for the first time at Paris, and spending some months in Spain and Portugal, the life and literatures of which had already strong attractions for him. Returning to America in the summer of 1819, he was inducted in the August following to the Smith professorship of French and Spanish literature and to the college professorship of belles-lettres at Harvard. The history and criticism of Spanish literature was in many respects a new subject at that time even in Europe,—the Spaniards themselves having no adequate treatment of their literature as a whole, and both Bouterwek and Sismondi having worked with scanty or second-hand resources. To supply this want, therefore, he gave his most serious thought, developing in his lectures the scheme of his more permanent work. In June, 1821, his father died, and in September he married Anna, daughter of Samuel Eliot, a merchant and founder of the chair of Greek literature at Harvard College. In the years following 1821 Ticknor made a vain effort to introduce measures of university reform. The death of his only son in 1834 and the subsequent failure of his wife's health led him to resign his post at Cambridge to Longfellow; and in the spring of 1835 he again went to Europe, where he remained until 1838. From that time till his death he lived chiefly at Boston. Till 1849 he published only occasional reviews and papers, such as his essays on Moore's *Anacreon*, on Milton's *Paradise Lost*, and on Thatcher's *Sermons*, in 1812; on Michael Stiefel, in 1816; on Griscom's *Tour in Europe* and on General La Fayette, in 1824; on amusements in Spain and on changes in Harvard College, in 1825; on Chateaubriand, in 1827; on Daniel Webster, in 1831; and on the best mode of teaching living languages, in 1832. His *History of Spanish Literature*, the first editions of which appeared in New York and London in 1849, was welcomed on all hands as the standard work on the subject, and was rapidly translated into Spanish and other Continental languages. Whatever its defects, it at least reduced to system and clearness a large mass of varied historical material hitherto only vaguely known; and its copious references to authorities and editions and its loving exploration of the by-ways of the literature made it as valuable to scholars as its direct and unpretentious style made it popular with general readers. In many respects it was the admirable literary complement of the historical work of Prescott. Like his, the bent of Ticknor's mind was expository rather than critical; and in both cases the standards applied were of a conventional rather than of an advanced nature. As with Prescott the glow of vivid narration often hides rather than reveals the underlying problems of social and philosophic import, so with Ticknor a certain fund of graceful and genial commonplace is apt to gloss over the really vital critical issues of the subject-matter. At crucial moments in place of the keener edge of criticism one is apt to find only the paper-knife intelligence of the ordinary book-lover. The defect, however, was common to the critical schools of the time. The merits of the work in its accurate survey of comparatively untrodden ground were individual and of an exceedingly high order. Ticknor subsequently took an active part in the establishment of the Boston public library, in the interests of which he paid in 1856 another visit to Europe, and to which he left at his death his fine collection of Spanish and Portuguese works. In 1859, on the death of Prescott, he at once began to collect materials for a life of his friend, which was published in 1864. His death took place at Boston on 26th January, 1871.

A *Life* of Ticknor, with his letters and journals, was edited by George S. Hillard, Boston, 1876.

TICONDEROGA, a village and township of the United States, in Essex county, New York, situated upon the stream connecting Lakes George and Champlain, and extending back upon an abrupt promontory which separates the two lakes. Two railroads enter the village,—the Delaware and Hudson and a branch of the Central Vermont. The population in 1880 was 3304.

Commanding the direct route from the St. Lawrence to the Hudson, Ticonderoga was early seized by the French and fortified under the name of Fort Carillon. In July, 1758 it was unsuccessfully attacked by Abercrombie. In the same month of the succeeding year it was abandoned by the French upon the approach of an English army under Amherst, who occupied it and greatly strengthened its works. At the beginning of the Revolution, in 1775, the fort was surprised and captured by Ethan Allen and a party of Vermont militia. In 1777 it was retaken by the English under Burgoyne and was held by them until the close of the war.

TIDES.

I. On the Nature of Tides.

§ 1. *Definition of Tide.*

Definition.

Atmospheric tides.

WHEN, as occasionally happens, a ship in the open sea meets a short succession of waves of very unusual magnitude, we hear of tidal waves; and the large wave caused by an earthquake is commonly so described. The use of the term "tide" in this connection is certainly incorrect, but it has perhaps been fostered by the fact that such waves impress their records on automatic tide-gauges, as, for example, when the wave due to the volcanic outbreak at Krakatoa was thus distinctly traceable in South Africa, and perhaps even faintly at Brest. We can only adequately define a tide by reference to the cause which produces it. A tide then is a rise and fall of the water of the sea produced by the attraction of the sun and moon. A rise and fall of the sea produced by a regular alternation of day and night breezes by regular rainfall and evaporation, or by any influence which the moon may have on the weather cannot strictly be called a tide. Such alternations may, it is true, be inextricably involved with the rise and fall of the true astronomical tide, but we shall here distinguish them as meteorological tides. These movements are the result of the action of the sun, as a radiating body, on the earth. Tides in the atmosphere would be shown by a regular rise and fall in the barometer, but such tides are undoubtedly very minute, and we shall not discuss them in this article, merely referring the reader to the *Mécanique Céleste* of Laplace, bks. i. and xiii. There are, however, very strongly marked diurnal and semidiurnal inequalities of the barometer due to atmospheric meteorological tides. Sir William Thomson in an interesting speculation[1] shows that the interaction of these quasi-tides with the sun is that of a thermodynamic engine, whereby there is caused a minute secular acceleration of the earth's rotation. This matter is, however, beyond the scope of the present article. We shall here extend the term "tide" to denote an elastic or viscous periodic deformation of a solid or viscous globe under the action of tide-generating forces. In the technical part of the article by the term "a simple tide" we shall denote a spherical harmonic deformation of the water on the surface of the globe, or of the solid globe itself, multiplied by a simple harmonic function of the time.

§ 2. *General Description of Tidal Phenomena.*[2]

High water retarded 50^{m} per diem.

Variability of interval after moon's transit.

If we live by the sea or on an estuary, we see that the water rises and falls nearly twice a day; speaking more exactly, the average interval from high water to high water is about 12^{h} 25^{m}, so that the average retardation from day to day is about 50^{m}. The times of high water are then found to bear an intimate relation with the moon's position. Thus at Ipswich high water occurs when the moon is nearly south, at London Bridge when it is southwest, and at Bristol when it is east-southeast. For a very rough determination of the time of high water it is sufficient to add the solar time of high water on the days of new and full moon (called the "establishment of the port") to the time of the moon's passage over the meridian, either visibly above or invisibly below the horizon. The interval between the moon's passage over the meridian and high water varies sensibly with the moon's age. From new moon to first quarter, and from full moon to third quarter (or rather from and to a day later than each of these phases), the interval diminishes from its average to a minimum and then increases again to the average; and in the other two quarters it increases from the average to a maximum, and then diminishes again to the average.

Spring and neap.

The range of the rise and fall of water is also subject to great variability. On the days after new and full moon the range of tide is at its maximum, and on the day after the first and third quarter at its minimum. The maximum is called "spring tide" and the minimum "neap tide," and the range of spring tide is usually between two and three times as great as that of neap tide. At many ports, however, especially non-European ones, two successive high waters are of unequal heights, and the law of variability of the difference is somewhat complex; a statement of that law will be easier when we come to consider tidal theories. In considering any tide we find, especially in estuaries, that the interval from high to low water is longer than that from low to high water, and the difference between the intervals is greater at spring than at neap.

River tides.

Distinction of rise and fall from flood and ebb.

In a river the current continues to run up stream for some considerable time after high water is attained and to run down similarly after low water. Much confusion has been occasioned by the indiscriminate use of the term "tide" to denote a tidal current and a rise of water, and it has often been incorrectly inferred that high water must have been attained at the moment of cessation of the upward current. The distinction between "rising and falling" and "flowing and ebbing" must be carefully maintained in rivers, whilst it vanishes at the seaboard. If we examine the progress of the tide-wave up a river, we find that high water occurs at the sea earlier than higher up. If, for instance, on a certain day it is high water at Margate at noon, it is high water at Gravesend at a quarter past two, and at London Bridge a few minutes before three. The interval from low to high water diminishes also as we go up the river; and at some distance up certain rivers—as, for example, the Severn—the rising water spreads over the flat sands in a roaring surf and travels up the river almost like a wall of water. This kind of sudden rise is called a "bore."[1] In other cases where the difference between the periods of rising and falling is considerable, there are, in each high water, two or three rises and falls. A double high water exists at Southampton.

[1] Société de Physique, September, 1881, or *Proc. Roy. Soc. of Edinburgh*, 1881-82, p. 396.

[2] Founded on Airy's "Tides and Waves," in *Ency. Metrop.*

Augmentation of height in estuaries.

When an estuary contracts considerably, the range of tide becomes largely magnified as it narrows; for example, at the entrance of the Bristol Channel the range of spring tides is about 18 feet, and at Chepstow about 50 feet. This augmentation of the height of the tide-wave is due to the concentration of the energy of motion of a large mass of water into a narrow space. At oceanic ports the tidal phenomena are much less marked, the range of tide being usually only 2 or 3 feet, and the interval from high to low water sensibly equal to that from low to high water. The changes from spring to neap tide and the relation of the time of high water to the moon's transit remain, however, the same as in the case of the river tides.

Land-locked seas.

In long and narrow seas, such as the English Channel, the tide in mid-channel follows the same law as at a station near the mouth of a river, rising and falling in equal times; the current runs in the direction analogous to up stream for three hours before and after high water, and down stream for the same period before and after low water. But near the sides of channels and near the mouths of bays the changes of the currents are very complex; and near the headlands separating two bays there is usually at certain times a very swift current, termed a "race."

In inland seas, such as the Mediterranean, the tides are nearly insensible except at the ends of long bays. Thus at Malta the tides are not noticed by the ordinary observer, whilst at Venice they are conspicuous.

Wind.

The effect of a strong wind on the height of tide is generally supposed to be very marked, especially in estuaries. In the case of an exceptional gale, when the wind veered round appropriately, Airy states[2] that the water has been known to depart from its predicted height at London by as much as 5 feet. The effect of wind will certainly be different at each port. The discrepancy of opinion on this subject appears to be great,—so much so that we hear of some observers concluding that the effect of the wind is insensible. Variations in barometric pressure also cause departures from the predicted height of water, high barometer corresponding to decrease of height of water. Roughly speaking, an inch of the mercury column will correspond to something less than a foot of water, but the effect seems to vary much at different ports.[3]

Atmospheric pressure.

§ 3. *General Explanation of the Cause of Tides.*

Tide generating forces.

The moon attracts every particle of the earth and ocean, and by the law of gravitation the force acting on any particle is directed towards the moon's centre, and is jointly proportional to the masses of the particle and of the moon, and inversely proportional to the square of the distance between the particle and the moon's centre. If we imagine the earth and ocean subdivided into a number of small portions or particles of equal mass, then the average, both as to direction and intensity, of the forces acting on these particles is equal to the force acting on that particle which is at the earth's centre. For there is symmetry about the line joining the centres of the two bodies, and, if we divide the earth into two portions by an ideal spherical surface passing through the earth's centre and having its centre at the moon, the portion remote from the moon is a little larger than the portion towards the moon, but the nearer portion is under the action of forces which are a little stronger than those acting on the further portion, and the resultant of the weaker forces on the larger portion is exactly equal to the resultant of the stronger forces on the smaller. If every particle of the earth and ocean were being urged by equal and parallel forces, there would be no cause for relative motion between the ocean and the earth. Hence it is the departure of the force acting on any particle from the average which constitutes the tide-generating force. Now it is obvious that on the side of the earth towards the moon the departure from the average is a small force directed towards the moon; and on the side of the earth away from the moon the departure is a small force directed away from the moon. Also these two departures are very nearly equal to one another, that on the near side being so little greater than that on the other that we may neglect the excess. All round the sides of the earth along a great circle perpendicular to the line joining the moon and earth, the departure is a force directed inwards towards the earth's centre. Thus we see that the tidal forces tend to pull the water towards and away from the moon, and to depress the water at right angles to that direction. If we could neglect the rotations of the bodies, and could consider the system as at rest, we should find that the water was in equilibrium when elongated into a prolate ellipsoid with its long axis directed towards and away from the moon.

Theory of equatorial canal on earth.

But it must not be assumed that this would be the case when there is motion. For, suppose that the ocean consisted of a canal round the equator, and that an earthquake or any other cause were to generate a great wave in the canal, this wave would travel along it with a velocity dependent on the depth. If the canal were about 13 miles deep, the velocity of the wave would be about 1000 miles an hour, and with depth about equal to the depth of our seas the velocity of the wave would be about half as great. We may conceive the moon's tide-generating force as making a wave in the canal and continually outstripping the wave it generates, for the moon travels along the equator at the rate of about 1000 miles an hour, and the sea is less than 13 miles deep. The resultant oscillation of the ocean must therefore be the summation of a series of partial waves generated at each instant by the moon and always falling behind her, and the aggregate wave, being the same at each instant, must travel 1000 miles an hour so as to keep up with the moon.

Now it is a general law of frictionless oscillation that, if a slowly varying periodic force acts on a system which would oscillate quickly if left to itself, the maximum excursion on one side of the equilibrium position occurs simultaneously with the maximum force in the direction of the excursion; but, if a quickly varying periodic force acts on a system which would oscillate slowly if left to itself, the maximum excursion on one side of the equilibrium position occurs simultaneously with the maximum force in the direction opposite to that of the excursion. An example of the first is a ball hanging by a short string, which we push slowly to and fro; the ball will never quit contact with the hand, and will agree with its excursions. If, however, the ball is hanging by a long string we can play at battledore and shuttlecock with it, and it always meets our blows. The latter is the analogue of the tides, for a free wave in our shallow canal goes slowly, whilst the moon's tide-generating action goes quickly. Hence, when the system is left to settle into steady oscillation, it is low water under and opposite to the moon, whilst the forces are such as to make it high water at those times.

Tides inverted.

---

[1] See a series of papers bearing on this kind of wave by Sir W. Thompson, in *Phil. Mag.*, 1886–87.

[2] Airy, "Tides and Waves."

[3] Airy, *op. cit.*, §§ 572–573.

If we consider the moon as revolving round the earth, the water assumes nearly the shape of an oblate spheroid with the minor axis pointed to the moon. The rotation of the earth in the actual case introduces a complexity which it is not easy to unravel by general reasoning. We can see, however, that if water moves from a lower to a higher latitude it arrives at the higher latitude with more velocity from west to east than is appropriate to its latitude, and it will move accordingly on the earth's surface. Following out this conception, we see that an oscillation of the water to and fro between south and north must be accompanied by an eddy. Laplace's solution of the difficult problem involved in working out this idea will be given below.

The conclusion at which we have arrived about the tides of an equatorial canal is probably more nearly true of the tides of a globe partially covered with land than if we were to suppose the ocean at each moment to assume the prolate figure of equilibrium. In fact, observation shows that it is more nearly low water than high water when the moon is on the meridian. If we consider how the oscillation of the water would appear to an observer carried round with the earth, we see that he will have low water twice in the lunar day, somewhere about the time when the moon is on the meridian, either above or below the horizon, and high water half way between the low waters.

Sun's influence.

If the sun be now introduced, we have another similar tide of about half the height, and this depends on solar time, giving low water somewhere about noon and midnight. The superposition of the two, modified by friction and by the interference of land, gives the actually observed aggregate tide, and it is clear that about new and full moon we must have spring tides and at quarter moons neap tides, and that (the sum of the lunar and solar tide-generating forces being about three times their difference) the range of spring tide will be about three times that of neap tide.

Diurnal tides.

So far we have supposed the luminaries to move on the equator; now let us consider the case where the moon is not on the equator. It is clear in this case that at any place the moon's zenith distance at the upper transit is different from her nadir distance at the lower transit. But the tide-generating force is greater the smaller the zenith or nadir distance, and therefore the forces are different at successive transits. This was not the case when the moon was deemed to move on the equator. Thus there is a tendency for two successive lunar tides to be of unequal heights, and the resulting inequality of height is called a "diurnal tide." This tendency vanishes when the moon is on the equator; and, as this occurs each fortnight, the lunar diurnal tide is evanescent once a fortnight. Similarly in summer and winter the successive solar tides are generally of unequal height, whilst in spring and autumn this difference is inconspicuous.

Evanescent in ocean of uniform depth.

One of the most remarkable conclusions of Laplace's theory of the tides, on a globe covered with ocean to a uniform depth, is that the diurnal tide is everywhere non-existent. But this hypothesis differs much from the reality, and in fact at some ports the diurnal tide is so large that during two portions of each lunation there is only one great high water and one great low water in each twenty-four hours, whilst in other parts of the lunation the usual semi-diurnal tide is observed.

§ 4. *Historical Sketch.*[1]

Kepler.

In 1687 Newton laid the foundation for all that has since been added to the theory of the tides when he brought his grand generalization of universal gravitation to bear on the subject. Kepler had indeed at an earlier date recognized the tendency of the water of the ocean to move towards the centres of the sun and moon, but he was unable to submit his theory to calculation. Galileo expresses his regret that so acute a man as Kepler should have produced a theory which appeared to him to reintroduce the occult qualities of the ancient philosophers. His own explanation referred the phenomenon to the rotation and orbital motion of the earth, and he considered that it afforded a principal proof of the Copernican system.

Newton.

In the 19th corollary of the 66th proposition of book i. of the *Principia*, Newton introduces the conception of a canal circling the earth, and he considers the influence of a satellite on the water in the canal. He remarks that the movement of each molecule of fluid must be accelerated in the conjunction and opposition of the satellite with the molecule, and retarded in the quadratures, so that the fluid must undergo a tidal oscillation. It is, however, in propositions 26 and 27 of book iii. that he first determines the tidal force due to the sun and moon. The sea is here supposed to cover the whole earth, and to assume at each instant a figure of equilibrium, and the tide-generating bodies are supposed to move in the equator. Considering only the action of the sun, he assumes that the figure is an ellipsoid of revolution with its major axis directed towards the sun, and he determines the ellipticity of such an ellipsoid. High solar tide then occurs at noon and midnight, and low tide at sunrise and sunset. The action of the moon produces a similar ellipsoid, but of greater ellipticity. The superposition of these ellipsoids gives the principal variations of tide. He then proceeds to consider the influence of latitude on the height of tide, and to discuss other peculiarities of the phenomenon. Observation shows, however, that spring tides occur a day and a half after syzygies, and Newton falsely attributed this to the fact that the oscillations would last for some time if the attractions of the two bodies were to cease.

"Astres fictifs."

Age of tide.

The Newtonian hypothesis, although it fails in the form which he gave to it, may still be made to represent the tides, if the lunar and solar ellipsoids have their major axes always directed towards a fictitious moon and sun, which are respectively at constant distances from the true bodies; these distances are such that the syzygies of the fictitious planets occur about a day or a day and a half later than the true syzygies. In fact, the actual tides may be supposed to be generated directly by the action of the real sun and moon, and the wave may be imagined to take a day and a half to arrive at the port of observation. This period has accordingly been called "the age of the tide." In what precedes the planets have been supposed to move in the equator; but the theory of the two ellipsoids cannot be reconciled with the truth when they move in orbits inclined to the equator. At equatorial ports the theory of the ellipsoids would at spring tides give morning and evening high waters of nearly equal height, whatever the declinations of the bodies. But at a port in any other latitude these high waters would be of very different heights, and at Brest, for example, when the declinations of the bodies are equal to the obliquity of the elliptic, the evening tide would be eight times as great as the morning tide. Now observation shows that at this port the two tides are nearly equal to one another, and that their greatest difference is not a thirtieth of their sum.

Newton here also offered an erroneous explanation of the phenomenon. In fact, we shall see that by Laplace's dynamical theory the diurnal tide is evanescent when the ocean is of uniform depth over the earth. At many non-European ports, however, the diurnal tide is very important, and thus as an actual means of prediction the dynamical theory, where the ocean is treated as of uniform depth, may be hardly better than the equilibrium theory.

---

[1] Founded on Laplace, *Mécanique Céleste*, bk. xiii. chap. i.

D. Bernoulli and others.

In 1738 the Academy of Sciences of Paris offered, as a subject for a prize, the theory of the tides. The authors of four essays received prizes, viz., Daniel Bernoulli, Euler, Maclaurin, and Cavalleri. The first three adopted not only the theory of gravitation but also Newton's method of the superposition of the two ellipsoids. Bernoulli's essay contained an extended development of the conception of the two ellipsoids, and, under the name of the equilibrium theory, it is commonly associated with his name. Laplace gives an account and critique of the essays of Bernoulli and Euler in the *Mécanique Céleste*. The essay of Maclaurin presented little that was new in tidal theory, but is notable as containing those theorems concerning the attraction of ellipsoids which we now know by his name. In 1746 D'Alembert wrote a paper in which he treated the tides of the atmosphere; but this work, like Maclaurin's, is chiefly remarkable for the importance of collateral points.

Laplace.

The theory of the tidal movements of an ocean was therefore, as Laplace remarks, almost untouched when in 1774 he first undertook the subject. In the *Mécanique Céleste* he gives an interesting account of the manner in which he was led to attack the problem. We shall give below the investigation of the tides of an ocean covering the whole earth; the theory is substantially Laplace's, although presented in a somewhat different form. This theory, although very wide, is far from representing the tides of our ports. Observation shows, in fact, that the irregular distribution of land and water and the variable depth of the ocean produce an irregularity in the oscillations of the sea of such complexity that the rigorous solution of the problem is altogether beyond the power of analysis. Laplace, however, rested his discussion of tidal observation on this principle—*The state of oscillation of a system of bodies in which the primitive conditions of movement have disappeared through friction is coperiodic with the forces acting on the system.* Hence, if the sea is solicited by a periodic force expressed as a coefficient multiplied by the cosine of an angle which increases proportionately with the time, there results a partial tide, also expressed by the cosine of an angle which increases at the same rate; but the phase of the angle and the coefficient of the cosine in the expression for the height may be very different from those occurring in the corresponding term of the equilibrium theory. The coefficients and the constants or epochs of the angles in the expressions for the tide are only derivable from observation. The action of the sun and moon is expressible in a converging series of similar cosines; whence there arise as many partial tides, which by the principle of superposition may be added together to give the total tide at any port. In order to unite the several constants of the partial tides Laplace considers each tide as being produced by a fictitious satellite moving uniformly on the equator. Sir W. Thomson and others have followed Laplace in this conception; but in the present article we shall not do so. The difference of treatment is in reality only a matter of phraseology, and the proper motion of each one of Laplace's *astres fictifs* is at once derivable from the *argument* (or angle under the sign of cosine), which we shall here associate with the partial tides.

Principle of forced oscillations.

Lubbock, Whewell, and Airy.

Subsequently to Laplace the most important workers in this field were Sir John Lubbock (senior), Whewell, and Airy. The work of Lubbock and Whewell (see § 34 below) is chiefly remarkable for the co-ordination and analysis of enormous masses of data at various ports, and the construction of trustworthy tide-tables and of cotidal maps. Airy contributed an important review of the whole tidal theory. He also studied profoundly the theory of waves in canals, and explained the effects of frictional resistances on the progress of tidal and other waves. Of other authors whose work is of great importance we shall speak below.

Amongst all the grand work which has been bestowed on this difficult subject, Newton, notwithstanding his errors, stands out first, and next to him we must rank Laplace. However original any future contribution to the science of the tides may be, it would seem as though it must perforce be based on the work of these two.

Bibliography.

A complete list of works bearing on the *theory* of the tides, from the time of Newton down to 1881, is contained in vol. ii. of the *Bibliographie de l'Astronomie* by Houzeau and Lancaster (Brussels, 1882). This list does not contain papers on the tides of particular ports, and we are not aware of the existence of any catalogue of works on practical observation, reduction of observations, prediction, and tidal instruments. References are, however, given below to several works on these points.

II. TIDE-GENERATING FORCES.

§ 5. *Investigation of Tide-generating Potential and Forces.*

We have already given a general explanation of the nature of tide-generating forces; we now proceed to a rigorous investigation.

Tide-generating forces.

If a planet is attended by a single satellite, the motion of any body relatively to the planet's surface is found by the process described as reducing the planet's centre to rest. The planet's centre will be at rest if every body in the system has impressed on it a velocity equal and opposite to that of the planet's centre; and this is accomplished by impressing on every body an acceleration equal and opposite to that of the planet's centre.

Let M, m be the masses of the planet and the satellite; r the radius vector of the satellite, measured from the planet's centre; ρ the radius vector, measured from the same point, of the particle whose motion we wish to determine; and z the angle between r and ρ. The satellite moves in an elliptic orbit about the planet, and the acceleration relatively to the planet's centre of the satellite is $(M+m)/r^2$ towards the planet along the radius vector r. Now the centre of inertia of the planet and satellite remains fixed in space, and the centre of the planet describes an orbit round that centre of inertia similar to that described by the satellite round the planet, but with linear dimensions reduced in the proportion of m to $M+m$. Hence the acceleration of the planet's centre is m/r^2 towards the centre of inertia of the two bodies. Thus, in order to reduce the planet's centre to rest, we apply to every particle of the system an acceleration m/r^2 parallel to r, and directed from satellite to planet.

Now take a set of rectangular axes fixed in the planet, and let $\mathrm{M}_1 r$, $\mathrm{M}_2 r$, $\mathrm{M}_3 r$ be the co-ordinates of the satellite referred thereto; and let $\xi\rho$, $\eta\rho$, $\zeta\rho$ be the co-ordinates of the particle P whose radius is ρ. Then the component accelerations for reducing the planet's centre to rest are $-m\mathrm{M}_1/r^2$, $-m\mathrm{M}_2/r^2$, $-m\mathrm{M}_3/r^2$; and since these are the differential co-efficients with respect to $\rho\xi$, $\rho\eta$, $\rho\zeta$ of the function

$$-\frac{m\rho}{r^2}(\mathrm{M}_1\xi+\mathrm{M}_2\eta+\mathrm{M}_3\zeta),$$

and since $\cos z=\mathrm{M}_1\xi+\mathrm{M}_2\eta+\mathrm{M}_3\zeta$, it follows that the potential of the forces by which the planet's centre is to be reduced to rest is

$$-\frac{m\rho}{r^2}\cos z.$$

Now let us consider the other forces acting on the particle. The planet is spheroidal, and therefore does not attract equally in all directions; but in this investigation we may make abstraction of the ellipticity of the planet and of the ellipticity of the ocean due to the planetary rotation. This, which we set aside, is considered in the theories of gravity and of the figures of planets. Outside of its body, then, the planet contributes forces of which the potential is M/ρ. Next the direct attraction of the satellite contributes forces of which the potential is the mass of the satellite divided by the distance between the point P and the satellite; this is—

$$\frac{m}{\sqrt{\{r^2+\rho^2-2r\rho\cos z\}}}.$$

To determine the forces from this potential we regard ρ and z as the variables for differentiation, and we may add to this potential any constant we please. As we are seeking to find the forces which urge P relatively to M, we add such a constant as will make the whole potential at the planet's centre zero, and thus we take as the potential of the forces due to the attraction of the satellite—

$$\frac{m}{\sqrt{\{r^2+\rho^2-2r\rho\cos z\}}}-\frac{m}{r}.$$

It is obvious that r is very large compared with ρ, and we may therefore expand this in powers of ρ/r. This expansion gives us

$$\frac{m}{r}\left\{\frac{\rho}{r}P_1+\frac{\rho^2}{r^2}P_2+\frac{\rho^3}{r^3}P_3+\text{etc.}\right\},$$

where $P_1=\cos z$, $P_2=\frac{3}{2}\cos^2 z-\frac{1}{2}$, $P_3=\frac{5}{2}\cos^3 z-\frac{3}{2}\cos z$, etc. The reader familiar with spherical harmonic analysis of course recognizes the Legendre's functions; but the result for a few terms, which is all that is necessary, is easily obtainable by simple algebra.

Now, collecting together the various contributions to the potential, and noticing that $\frac{m}{r}\cdot\frac{\rho}{r}P_1=\frac{m\rho}{r^2}\cos z$, and is therefore equal and opposite to the potential by which the planet's centre was reduced to rest, we have as the potential of the forces acting on a particle whose co-ordinates are $\rho\xi$, $\rho\eta$, $\rho\zeta$

$$\frac{M}{\rho}+\frac{m\rho^2}{r^3}(\tfrac{3}{2}\cos^2 z-\tfrac{1}{2})+\frac{m\rho^3}{r^4}(\tfrac{5}{2}\cos^3 z-\tfrac{3}{2}\cos z)+\ldots\ldots\ldots(1.)$$

Potential.

The first term of (1) is the potential of gravity, and the terms of the series, of which two only are written, constitute the tide-generating potential. In all practical applications this series converges so rapidly that the first term is amply sufficient, and thus we shall generally denote

$$V=\frac{3m}{2r^3}\rho^2(\cos^2 z-\tfrac{1}{3})\;\ldots\ldots\ldots\ldots\ldots\ldots\ldots\;(2)$$

as the tide-generating potential.

Moon and anti-moon.

In many mathematical works the tide-generating force is presented as being due to an artificial statical system, which produces nearly the same force as the dynamical system considered above. This statical system is as follows. Stopping all the rotations, we divide the satellite into two equal parts, and place them diametrically opposite to one another in the orbit. Then it is clear that, instead of the term

$$\frac{m}{\sqrt{\{r^2+\rho^2-2r\rho\cos z\}}}-\frac{m}{r},$$

we have

$$\frac{\frac{1}{2}m}{\sqrt{\{r^2+\rho^2-2r\rho\cos z\}}}+\frac{\frac{1}{2}m}{\sqrt{\{r^2+\rho^2+2r\rho\cos z\}}}-\frac{m}{r}.$$

and this reduces to

$$\frac{m}{r^3}\rho^2P_2+\frac{m}{r^5}\rho^4P_4+\ldots$$

The first term is the same as before; hence the statical system produces approximately the same tide-generating force as the true system. The "moon" and "anti-moon," however, produce rigorously the same force on each side of the planet, whereas the true system only satisfies this condition approximately.[1]

§ 6. *Form of Equilibrium.*

Let us consider the shape assumed by a layer of fluid of density σ, lying on a globe of mass M, when acted on by disturbing forces whose potential is

$$V=\frac{3m}{2r^3}\rho^2(\cos^2 z-\tfrac{1}{3})\ldots\ldots\ldots\ldots\ldots\ldots\ldots(3).$$

Suppose the layer to be very thin, and that the mean radius of the layer is a, and let the equation to the boundary of the fluid be

$$\rho=a[1+\mathfrak{e}(\cos^2 z-\tfrac{1}{3})]\ldots\ldots\ldots\ldots\ldots\ldots\ldots(4).$$

We assume this form, because the theory of harmonic analysis tells us that the departure from sphericity must be represented by a function of the form $\cos^2 z-\frac{1}{3}$. That theory also gives us as the potential of a layer of matter of depth $\mathfrak{e}a(\cos^2 z-\frac{1}{3})$, and density σ, at an external point the value

$$\tfrac{4}{5}\pi\sigma a^2\left(\frac{a}{\rho}\right)^3\mathfrak{e}(\cos^2 z-\tfrac{1}{3}).$$

Hence the whole potential, outside of and up to the fluid layer, is

$$\frac{M}{\rho}+\frac{3m}{2r^3}\rho^2(\cos^2 z-\tfrac{1}{3})+\tfrac{4}{5}\pi\sigma a^2\left(\frac{a}{\rho}\right)^3\mathfrak{e}(\cos^2 z-\tfrac{1}{3})\ldots\ldots(5).$$

The first term of (5) is the potential of the globe, the second that of the disturbing force, and the third the potential due to departure from sphericity.

Now the fluid must stand in a level surface; hence, if we equate this potential to a constant, we must get back to the equation (4), which was assumed to be that of the surface. In other words, if we put $\rho=a[1+\mathfrak{e}(\cos^2 z-\frac{1}{3})]$ in (5), the result must be constant, provided the departure from sphericity is small. In effecting the substitution for ρ, we may put $\rho=a$ in the small terms, but in the first term of (5) we put

$$\frac{M}{\rho}=\frac{M}{a}[1-\mathfrak{e}(\cos^2 z-\tfrac{1}{3})].$$

The whole potential (5) can only be constant if, after this substitution, the coefficient of $\cos^2 z-\frac{1}{3}$ vanishes. Thus we must have

$$-\frac{M}{a}\mathfrak{e}+\frac{3ma^2}{2r^3}+\tfrac{4}{5}\pi\sigma a^2\mathfrak{e}=0.$$

But if δ be the mean density of the planet $M=\frac{4}{3}\pi a^3\delta$, and gravity $g=M/a^2$. Then we easily find that

$$\mathfrak{e}=\frac{3ma}{2gr^3}\,\frac{1}{1-\frac{3}{5}\sigma/\delta}\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(6).$$

Thus the equation to the surface is

$$r=a\left\{1+\frac{3ma}{2gr^3}\,\frac{1}{1-\frac{3}{5}\sigma/\delta}(\cos^2 z-\tfrac{1}{3})\right\}\ldots\ldots\ldots(7).$$

Form of equilibrium.

If σ be small compared with δ, the coefficient is $3ma/2gr^3$; thus we see that $1/(1-\frac{3}{5}\sigma/\delta)$ is the coefficient by which the mutual attraction of the fluid augments the deformation of the fluid under the action of the disturbing force. If the density of the fluid be the same as that of the sphere, the augmenting factor becomes $\frac{5}{2}$, and we have $\mathfrak{e}=\frac{15}{4}ma/gr^3$, which gives the form of equilibrium of a fluid sphere under the action of these forces. Since $\frac{3m}{2r^3}=\frac{g}{a}\left(1-\frac{3\sigma}{5\delta}\right)\mathfrak{e}$, it follows that, when the form of equilibrium is $\rho=a[1+\mathfrak{e}(\cos^2 z-\frac{1}{3})]$, the potential of the forces is

$$V=\frac{g}{a}\left(1-\frac{3\sigma}{5\delta}\right)\mathfrak{e}\rho^2(\cos^2 z-\tfrac{1}{3})\ldots\ldots\ldots\ldots\ldots(8).$$

More generally, if we neglect the attraction of the fluid on itself, so that σ/δ is treated as small, and if $\rho=a(1+\varsigma)$ be the equation to the surface of the fluid, where ς is a function of latitude and longitude, then the potential of the forces under which this is an equilibrium form is

$$V=\frac{g\rho^2}{a}\varsigma\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(9).$$

Tide-generating force specified by equilibrium form.

It thus appears that we may specify any tide-generating forces by means of the figure of equilibrium which the fluid would assume under them, and in the theory of the tides it has been found practically convenient to specify the forces in this way.

By means of the principle of "forced vibrations" referred to in the historical sketch, we shall pass from the equilibrium form to the actual oscillations of the sea.

§ 7. *Development of Tide-generating Potential in Terms of Hour-Angle and Declination.*

Development of tide-generating potential.

We now proceed to develop the tide-generating potential, and shall of course implicitly (§ 6) determine the equation to the equilibrium figure.

We have already seen that, if z be the moon's zenith distance at the point P on the earth's surface, whose co-ordinates referred to A, B, C, axes fixed in the earth, are $a\xi$, $a\eta$, $a\zeta$, then

$$\cos z=\xi\mathrm{M}_1+\eta\mathrm{M}_2+\zeta\mathrm{M}_3,$$

where M_1, M_2, M_3 are the moon's direction cosines referred to the same axes. Then with this value of $\cos z$—

$$\cos^2 z-\tfrac{1}{3}=2\xi\eta\mathrm{M}_1\mathrm{M}_2+2\frac{\xi^2-\eta^2}{2}\,\frac{\mathrm{M}_1^2-\mathrm{M}_2^2}{2}+2\eta\zeta\mathrm{M}_2\mathrm{M}_3$$
$$+2\xi\zeta\mathrm{M}_1\mathrm{M}_3+\frac{3}{2}\cdot\frac{\xi^2+\eta^2-2\zeta^2}{3}\,\frac{\mathrm{M}_1^2+\mathrm{M}_2^2-2\mathrm{M}_3^2}{3}\ldots(10).$$

The axis of C is taken as the polar axis, and AB is the equatorial plane, so that the functions of ξ, η, ζ are functions of the latitude and longitude of the point P, at which we wish to find the potential.

The functions of M_1, M_2, M_3 depend on the moon's position, and we shall have occasion to develop them in two different ways,—first in terms of her hour-angle and declination, and secondly (§ 23) in terms of her longitude and the elements of the orbit.

---

[1] The reader may refer to Thomson and Tait's *Natural Philosophy* (1883), part ii. §§ 798–821, for further considerations on this and analogous subjects, together with some interesting examples.

Now let A be on the equator in the meridian of *P*, and B 90° east of A on the equator. Then, if M be the moon, the inclination of the plane MC to the plane CA is the moon's easterly local hour-angle. Let h = local hour-angle of moon and δ = moon's declination: we have

$$M_1 = \cos\delta\cos h,\ M_2 = \cos\delta\sin h,\ M_3 = \sin\delta,$$

whence

$$2M_1M_2 = \cos^2\delta\sin 2h,\ M_1^2 - M_2^2 = \cos^2\delta\cos 2h,$$
$$2M_2M_3 = 2\sin\delta\cos\delta\sin h,\ 2M_1M_3 = 2\sin\delta\cos\delta\cos h,$$
$$\frac{M_1^2 + M_2^2 - 2M_3^2}{3} = \tfrac{1}{3} - \sin^2\delta.$$

Also, if λ be the latitude of *P*,

$$\xi = \cos\lambda,\ \eta = 0,\ \zeta = \sin\lambda,$$

and

$$\xi\eta = 0,\ \frac{\xi^2 - \eta^2}{2} = \tfrac{1}{2}\cos^2\lambda,\ \xi\zeta = \tfrac{1}{2}\sin 2\lambda,\ \xi\eta = 0,$$
$$\tfrac{1}{3}(\xi^2 + \eta^2 - 2\zeta^2) = \tfrac{1}{3} - \sin^2\lambda.$$

Hence (10) becomes

$$\cos^2 z - \tfrac{1}{3} = \tfrac{1}{2}\cos^2\lambda\cos^2\delta\cos 2h + \sin 2\lambda\sin\delta\cos\delta\cos h$$
$$+ \tfrac{3}{2}(\tfrac{1}{3} - \sin^2\delta)(\tfrac{1}{3} - \sin^2\lambda)\ \ldots\ldots\ldots\ldots(11).$$

The angle h, as defined at present, is the eastward local hour-angle, and therefore diminishes with the time. As, however, this function does not change sign with h, it will be more convenient to regard it as the westward local hour-angle. Also, if h_0 be the Greenwich westward hour-angle at the moment under consideration, and l be the west longitude of the place of observation *P*, we have

$$h = h_0 - l\ \ldots\ldots\ldots\ldots(12).$$

Hence we have at the point *P*, whose radius vector is a,

$$V = \frac{3ma^2}{2r^3}\left\{\tfrac{1}{2}\cos^2\lambda\cos^2\delta\cos 2(h_0 - l) + \sin 2\lambda\sin\delta\cos\delta\cos(h_0 - l) + \tfrac{3}{2}(\tfrac{1}{3} - \sin^2\delta)(\tfrac{1}{3} - \sin^2\lambda)\right\}\ \ldots\ldots\ldots\ldots(13).$$

Potential developed in hour-angle and declination.

The tide-generating forces are found by the rates of variation of V for latitude and longitude, and also for radius a, if we care to find the radial disturbing force.

§ 8. *Evaluation of Tide-generating Forces, and Lunar Deflection of Gravity.*

The westward component of the tide-generating force at the earth's surface, where $\rho = a$, is $dV/a\cos\lambda dl$, and the northward component is $dV/ad\lambda$; the change of apparent level is the ratio of these to gravity g. Therefore, differentiating (13), changing signs, and writing $\frac{3m}{2M}\left(\frac{a}{r}\right)^3$ for $\frac{3ma}{2gr^3}$, we have component change of level southward

$$= \frac{3m}{4M}\left(\frac{a}{r}\right)^3\left\{\sin 2\lambda\cos^2\delta\cos 2(h_0 - l) - 2\cos 2\lambda\sin 2\delta\cos(h_0 - l) + \sin 2\lambda(1 - 3\sin^2\delta)\right\};$$

component change of level westward

$$= \frac{3m}{2M}\left(\frac{a}{r}\right)^3\left\{\cos\lambda\cos^2\delta\sin 2(h_0 - l) + \sin\lambda\sin 2\delta\sin(h_0 - l)\right\}\ \ldots\ldots(14).$$

Lunar deflection of gravity.

The westward component is made up of two periodic terms, one going through its variations twice and the other once a day. The southward component has also two similar terms; but it has a third term, which does not oscillate about a zero value. If Δ be a declination such that the mean value of $\sin^2\delta$ is equal to $\sin^2\Delta$, then to determine the southward component so that it shall be a truly periodic function, we must subtract from the above $\sin 2\lambda(1 - 3\sin^2\Delta)$, and the last term then becomes

$$3\sin 2\lambda(\sin^2\Delta - \sin^2\delta).$$

In the case of the moon, Δ varies a little according to the position of the moon's node, but its mean value is about 16° 31′.

The constant portion of the southward component of force has its effect in causing a constant heaping up of the water at the equator; or, in other words, the moon's attraction has the effect of causing a small permanent ellipticity of the earth's mean figure. This augmentation of ellipticity is of course very small, but it is necessary to mention it in order that the meaning to be attributed to lunar deflection of gravity may be clearly defined.

If we consider the motion of a pendulum-bob during any one day, we see that in consequence of the semi-diurnal changes of level, it twice describes an ellipse with major axis east and west, with ratio of axes equal to the sine of the latitude, and with linear dimensions proportional to $\cos^2\delta$, and it once describes an ellipse whose north and south axis is proportional to $\sin 2\delta\cos 2\lambda$ and whose east and west axis is proportional to $\sin 2\delta\sin\lambda$. Obviously the latter is circular in latitude 30°. When the moon is on the equator, the maximum deflection occurs when the moon's local hour-angle is 45°, and is then equal to

$$\frac{3m}{2M}\left(\frac{a}{r}\right)^3\cos\lambda.$$

At Cambridge in latitude 52° 43′ this angle is 0.0216″.

An attempt, made by George and Horace Darwin,[1] to measure the lunar deflection of a pendulum failed on account of incessant variability of level occurring in the supports of the pendulum and arising from unknown terrestrial changes. The work done, therefore, was of no avail for the purpose for which it was instituted, but remained as a contribution to an interesting subject now beginning to be studied, viz., the small changes which are always taking place on the upper strata of the earth.

§ 9. *Correction to Equilibrium Theory for Continents.*

Effect of land in equilibrium theory.

In the equilibrium theory as worked out by Newton and Bernoulli it is assumed that the figure of the ocean is at each instant one of equilibrium under the action of gravity and of the tide-generating forces. Sir W. Thomson has, however, reasserted[2] a point which was known to Bernoulli, but has since been overlooked, namely, that this law of rise and fall of water cannot, when portions of the globe are continents, be satisfied by a constant volume of water in the ocean. The law would still hold if water were appropriately supplied to and exhausted from the ocean; and, if in any configuration of the tide-generating body we imagine water to be instantaneously so supplied or exhausted, the level will everywhere rise or fall by the same height. Now the amount of that rise or fall depends on the position of the tide-generating body with reference to the continents, and is different for each such position. Conversely, when the volume of the ocean remains constant, we have to correct Bernoulli's simple equilibrium theory by an amount which is constant all over the globe at any instant, but which changes in time. Thomson's solution of this problem has since been reduced to a form which is easier to grasp intelligently than in the shape in which he gave it, and the results have also been reduced to numbers.[3] It appears that there are four points on the earth's surface at which in the corrected theory the semi-diurnal tide is evanescent, and four others where it is doubled. A similar statement holds for the diurnal tide. As to the tides of long period, there are two parallels of latitude of evanescent and two of doubled tide.

Now in Bernoulli's theory the semi-diurnal tide vanishes at the poles, the diurnal tide at the poles and the equator, and the tides of long period in latitudes 35° 16′ north and south. The numerical solution of the corrected theory shows that the points and lines of doubling and evanescence in every case fall close to the points and lines where in the uncorrected theory there is evanescence. When in passing from the uncorrected to the corrected theory we speak of a doubled tide, the tide doubled may be itself *nil*, so that the result may still be *nil*. The conclusion, therefore, is that Thomson's correction, although theoretically interesting, is practically so small that it may be left out of consideration.

III. Dynamical Theory of Tides.

§ 10. *Historical Explanation.*

Dynamical theory.

The problem of tidal oscillation is essentially a dynamical one. Even when the ocean is taken as covering the whole earth, it presents formidable difficulties, and this is the only case in which it has been hitherto solved.[4] Laplace gives the solution in bks. i. and iv. of the *Mécanique Céleste*; but his work is unnecessarily complicated by the inappropriate introduction of spherical harmonic analysis, and it is generally admitted that his investigation is difficult. Airy, in his "Tides and Waves" (in *Ency. Metrop.*), presents the solution free from that complication, but he has made a criticism of Laplace's method which we believe to be wrong. Sir W. Thomson has written some interesting papers (in *Phil. Mag.*, 1875) in justification of Laplace, and on these we base the following paragraphs. This portion of the article is given more fully than others, because there exist no complete presentment of the theory free from objections of some kind.

---

[1] *Reports to the British Assoc.*, 1881 (York) and 1882 (Southampton).

[2] Thomson and Tait, *Nat. Phil.*, § 807.

[3] Darwin and Turner, *Proc. Roy. Soc.*, 1886.

[4] Sir W. Thomson's paper "On the gravitational Oscillations of Rotating Water," in *Phil. Mag.*, August, 1880, bears on the same subject. It is the only attempt which has hitherto been made to consider the effects of the earth's rotation on the oscillations of land-locked seas.

§ 11. *Equations of Motion.*

Equations of motion.

Let r, θ, ϕ be the radius vector, co-latitude, and east longitude of a point with reference to an origin, a polar axis, and a zero-meridian rotating with a uniform angular velocity n from west to east. Then, if R, H, Ξ be the radial, co-latitudinal, and longitudinal accelerations of the point, we have

$$\left.\begin{aligned} R &= \frac{d^2r}{dt^2} - r\left(\frac{d\theta}{dt}\right)^2 - r\sin^2\theta\left(\frac{d\phi}{dt}+n\right)^2 \\ \Xi &= \frac{1}{r}\frac{d}{dt}\left(r^2\frac{d\theta}{dt}\right) - r\sin\theta\cos\theta\left(\frac{d\phi}{dt}+n\right)^2 \\ H &= \frac{1}{r\sin\theta}\frac{d}{dt}\left[r^2\sin^2\theta\left(\frac{d\phi}{dt}+n\right)\right] \end{aligned}\right\} (15).$$

Now suppose that the point never moves far from a zero position and that its displacements ξ, $\eta\sin\theta$ co-latitudinally and longitudinally are very large compared with its radial displacement ρ, and that the velocities are so small that their squares and products are negligible compared with n^2r^2; then we have

$$\frac{dr}{dt}=\frac{d\rho}{dt},\ \text{a very small quantity};$$

$$r\sin\theta\frac{d\phi}{dt}=\frac{d}{dt}(\eta\sin\theta),$$

$$r\frac{d\theta}{dt}=\frac{d\xi}{dt}.$$

Hence (15) is approximately

$$\left.\begin{aligned} R &= -n^2r\sin^2\theta \\ \Xi &= \frac{d^2\xi}{dt^2} - 2n\sin\theta\cos\theta\frac{d\eta}{dt} \\ H &= \sin\theta\frac{d^2\eta}{dt^2} + 2n\cos\theta\frac{d\xi}{dt} \end{aligned}\right\} \text{.........}(16).$$

Component accelerations.

With regard to the first equation of (16), we observe that the time has disappeared, and that R has exactly the same form as if the system were rendered statical by introducing a potential $\frac{1}{2}n^2r^2\sin^2\theta$ and annulling the rotation of the axes. Since inertia plays no sensible part radially, it follows that, if we apply these expressions to the formation of equations of motion for the ocean, the radial motion need not be considered. We are left, therefore, with only the last two equations of (16).

Component forces.

We now have to consider the forces by which an element of the ocean is urged in the direction of co-latitude and longitude. These forces are those due to the external disturbing forces and to the pressure of the surrounding fluid, the attraction of the fluid on itself being supposed negligible. We have seen in (9) that, if fluid on a sphere of radius a be under the action of disturbing forces whose potential is Ur^2, and if $r=a+\mathfrak{h}$ be the equation to the surface, then must $g\mathfrak{h}=Ua^2$. Hence, if $\mathfrak{E}$ be the equilibrium height of tide, the potential of the disturbing force is $g\mathfrak{E}r^2/a^2$. But, if the elevation be $\mathfrak{h}$, the potential under which it would be in equilibrium is $g\mathfrak{h}r^2/a^2$. Therefore, if $\mathfrak{h}$ be the elevation of the tide in our dynamical problem, the forces due to hydrostatic pressure on an element of the ocean are the same as would be caused by a potential $-g\mathfrak{h}r^2/a^2$. Hence it follows that the whole forces on the element are those due to a potential $-g(\mathfrak{h}-\mathfrak{E})r^2/a^2$. Therefore from (16) we see that the equations of motion are

$$\left.\begin{aligned} \frac{d^2\xi}{dt^2} - 2n\sin\theta\cos\theta\frac{d\eta}{dt} &= -\frac{g}{a}\frac{d}{d\theta}(\mathfrak{h}-\mathfrak{E}) \\ \sin\theta\frac{d^2\eta}{dt^2} + 2n\cos\theta\frac{d\xi}{dt} &= -\frac{g}{a\sin\theta}\frac{d}{d\phi}(\mathfrak{h}-\mathfrak{E}) \end{aligned}\right\} \text{...}(17).$$

Equations of motion.

It remains to find the equation of continuity. This may be deduced geometrically from the consideration that the volume of an element of the fluid remains constant; but a shorter way is to derive it from the equation of continuity as it occurs in ordinary hydrodynamical investigations. If V be a velocity potential, the equation of continuity for incompressible fluid is

$$\delta r\frac{d}{dr}\left(r^2\frac{dV}{dr}\sin\theta\,\delta\theta\,\delta\phi\right)+\delta\theta\frac{d}{d\theta}\left(r\sin\theta\frac{dV}{rd\theta}\delta r\,\delta\phi\right)$$
$$+\delta\phi\frac{d}{d\phi}\left(r\frac{1}{r\sin\theta}\frac{dV}{d\phi}\delta r\,\delta\theta\right)=0.$$

The element referred to in this equation is defined by r, θ, ϕ, $r+\delta r$, $\theta+\delta\theta$, $\phi+\delta\phi$. The co-latitudinal and longitudinal velocities are the same for all the elementory prism defined by θ, ϕ, $\theta+\delta\theta$, $\phi+\delta\phi$, and the sea bottom. Then $\frac{dV}{rd\theta}=\frac{d\xi}{dt}$, $\frac{dV}{r\sin\theta\,d\phi}=\sin\theta\frac{d\eta}{dt}$; and, since the radial velocity is $d\mathfrak{h}/dt$ at the surface of the ocean, where $r=a+\gamma$, and is zero at the sea bottom, where $r=a$, we have $\frac{dV}{dr}=\frac{r-a}{\gamma}\frac{d\mathfrak{h}}{dt}$. Hence, integrating with respect to r from $r=a+\gamma$ to $r=a$, and again with respect to t from the time t to the time when $\mathfrak{h}$, ξ, η all vanish, and treating γ and $\mathfrak{h}$ as small compared with, we have

$$\mathfrak{h}a\sin\theta+\frac{d}{d\theta}(\gamma\xi\sin\theta)+\frac{d}{d\phi}(\gamma\eta\sin\theta)=0\text{......}(18).$$

Equation of continuity.

This is the equation of continuity, and, together with (17), it forms the system which must be integrated in the general problem of the tides. The difficulties in the way of a solution are so great that none has hitherto been found, except on the supposition that γ, the depth of the ocean, is only a function of latitude. In this case (18) becomes

$$\mathfrak{h}a+\frac{1}{\sin\theta}\frac{d}{d\theta}(\gamma\xi\sin\theta)+\gamma\frac{d\eta}{d\phi}\text{..............}(19).$$

§ 12. *Adaptation to Forced Oscillations.*

Adaptation to forced oscillations.

Since we may suppose that the free oscillations are annulled by friction, the solution required is that corresponding to forced oscillations. Now we have seen from (13) that $\mathfrak{E}$ (which is proportional to V) has terms of three kinds, the first depending on twice the moon's (or sun's) hour-angle, the second on the hour-angle, and the third independent thereof. The coefficients of the first and second terms vary slowly, and the whole of the third varies slowly. Hence $\mathfrak{E}$ has a semi-diurnal, a diurnal, and a long period term. We shall see later that these terms may be expanded in a series of approximately semi-diurnal, diurnal, and slowly varying terms, each of which is a strictly harmonic function of the time. Thus we may assume for $\mathfrak{E}$ a form $\mathrm{e}\cos(2nft+k\phi+\alpha)$, where f and k are numbers, and where e is only a function of co-latitude and of the elements of the orbit of the disturbing body. According to the usual method of treating oscillating systems, we may therefore make the following assumption for the form of solution

$$\left.\begin{aligned} \mathfrak{E} &= \mathrm{e}\cos(2nft+k\phi+\alpha) \\ \mathfrak{h} &= \mathrm{h}\cos(2nft+k\phi+\alpha) \\ \xi &= \mathrm{x}\cos(2nft+k\phi+\alpha) \\ \eta &= \mathrm{y}\sin(2nft+k\phi+\alpha) \end{aligned}\right\} \text{..... ......}(20).$$

where e, h, x, y are functions of co-latitude θ only. Substituting these values in (19), we have

$$\frac{1}{\sin\theta}\frac{d}{d\theta}(\gamma\mathrm{x}\sin\theta)+k\gamma\mathrm{y}+\mathrm{h}a=0\text{.........}(21).$$

Then, if we write u for h − e, and put $m=n^2a/g$, substitution from (20) in (17) leads at once to

$$\left.\begin{aligned} \mathrm{x}f^2+\mathrm{y}f\sin\theta\cos\theta &= \frac{1}{4m}\frac{d\mathrm{u}}{d\theta} \\ \mathrm{y}f^2\sin\theta+\mathrm{x}f\cos\theta &= -\frac{k}{4m}\frac{\mathrm{u}}{\sin\theta} \end{aligned}\right\} \text{.......}(22).$$

Solving (22) for x and y, we have

$$\left.\begin{aligned} \mathrm{x}(f^2-\cos^2\theta) &= \frac{1}{4m}\left(\frac{d\mathrm{u}}{d\theta}+\frac{k}{f}\mathrm{u}\frac{\cos\theta}{\sin\theta}\right) \\ \mathrm{y}\sin\theta(f^2-\cos^2\theta) &= \frac{-1}{4m}\left(\frac{\cos\theta}{f}\frac{d\mathrm{u}}{d\theta}+\frac{k\mathrm{u}}{\sin\theta}\right) \end{aligned}\right\} (23).$$

Then substituting from (23) in (21), we have

$$\frac{1}{\sin\theta}\frac{d}{d\theta}\left[\frac{\gamma\left(\sin\theta\frac{d\mathrm{u}}{d\theta}+\frac{k}{f}\mathrm{u}\cos\theta\right)}{f^2-\cos^2\theta}\right]-k\gamma\frac{\frac{\cos\theta}{f}\frac{d\mathrm{u}}{d\theta}+\frac{k\mathrm{u}}{\sin\theta}}{\sin\theta(f^2-\cos^2\theta)}$$
$$+4ma(\mathrm{u}+\mathrm{e})=0\text{.................}(24).$$

Final equation.

This is Laplace's equation for tidal oscillations in an ocean whose depth is only a function of latitude. When u is found from this equation, its value substituted in (23) will give x and y.

§ 13. *Preparation for Solution.*

Preparation for solution.

The ocean which is considered in this case is not like that on the earth's surface, and therefore it does not seem desirable to pursue the integration of (24) except in certain typical cases.

In (13) we have the expansion of the disturbing potential and implicitly of the disturbing forces in three terms, the first of which is variable in half a day, the second in a day, and the third in half the period of revolution of the tide-raising body. Forestalling the results of chapter iv.—each of these terms may be expressed as the sum of a series of strictly harmonic functions of the time; the first set of these have all approximately semi-diurnal periods, and the second approximately diurnal periods, and the third vary slowly in dependence on the periodic time of the tide-generating body. The first set involve twice the terrestrial longitude, the second the longitude, and the third set are independent of the longitude of the place of observation. From these statements compared with (13) we see that in the semi-diurnal terms f is approximately unity, $k=2$, and $\mathfrak{e}=\mathrm{E}\sin^2\theta$; in the diurnal terms f is approximately $\frac{1}{2}$, $k=1$, and $\mathfrak{e}=\mathrm{E}\sin\theta\cos\theta$; in the terms of long period f is a small fraction (for the fortnightly tide about $\frac{1}{28}$), $k=0$, $\mathfrak{e}=\mathrm{E}\left(\frac{1}{3}-\cos^2\theta\right)$. The departure from exactness in the relation $f=1$ for the semi-diurnal, and $f=\frac{1}{2}$ for the diurnal terms is generally (except for certain critical depths of ocean) not such as to greatly change the nature of the results from those obtained when $f=1$ and $\frac{1}{2}$ rigorously. Hence the integration of (24) will be pursued on these three hypotheses, giving Laplace's three kinds of oscillation. The hypothesis which will be made with regard to γ is that $\gamma=l(1-q\cos^2\theta)$, and in the case of the semi-diurnal tides we shall be compelled by mathematical difficulties to suppose q to be either unity or zero. The tides of zonal seas may be worked out, and more complex laws of depth may be assumed; but for the discussion of such cases the reader is referred to Thomson's papers in *Phil. Mag.*, 1875.

Laplace's three kinds of oscillation.

There might be reason to conjecture that the form of u would be similar to that of e, and this is in fact the case for the diurnal tides for any value of q and for the semi-diurnal tides when q is unity. Before proceeding further it will be convenient to exhibit two purely analytical transformations of the first two terms of (24) which hold true for certain values of k and f, and when u has such a form as that suggested. If we put $k=1$, $f=\frac{1}{2}$, $\gamma=l(1-q\cos^2\theta)$, then, if $v=A\sin\theta\cos\theta$, it will be found on substitution that

Preliminary transformations.

$$\frac{1}{\sin\theta}\frac{d}{d\theta}\,\frac{\gamma\left(\sin\theta\dfrac{dv}{d\theta}+2v\cos\theta\right)}{\frac{1}{4}-\cos^2\theta}-\gamma\,\frac{2\cot\theta\dfrac{dv}{d\theta}+\dfrac{v}{\sin^2\theta}}{\frac{1}{4}-\cos^2\theta}=-8lqv\text{......}(25).$$

Again, if we put $k=2$, $f=1$, $q=1$, $\gamma=l\,1-\cos^2\theta)=l\sin^2\theta$, and if $v=A\sin^2\theta$,

$$\frac{1}{\sin\theta}\frac{d}{d\theta}\,\frac{\gamma\left(\sin\theta\dfrac{dv}{d\theta}+2v\cos\theta\right)}{1-\cos^2\theta}-2\gamma\,\frac{\cot\theta\dfrac{dv}{d\theta}+\dfrac{2v}{\sin^2\theta}}{1-\cos^2\theta}=-8lv\text{......}(26).$$

Another general property of (24) is derived from the supposition that u is expressed in a series proceeding by powers of l; thus

$$\mathrm{u}=v_0+v_1\frac{l}{a}+v_2\frac{l^2}{a^2}+\text{..................}(27).$$

Let v_0, v_1, v_2, etc., be so chosen that, when u is substituted in (24), the coefficient of each power of l vanishes independently; then the term independent of l obviously gives $v_0=-\mathrm{e}$, and the connection between successive v's is

$$\frac{1}{\sin\theta}\frac{d}{d\theta}\left[\frac{\gamma\left(\sin\theta\dfrac{dv_m}{d\theta}+\dfrac{k}{f}v_m\cos\theta\right)}{f^2-\cos^2\theta}\right]-k\gamma\frac{\left(\dfrac{\cos\theta}{f}\dfrac{dv_m}{d\theta}+\dfrac{kv_m}{\sin\theta}\right)}{\sin\theta\,(f^2-\cos^2\theta)}+4mlv_{m+1}=0\text{........................}(28).$$

We shall suppose below that u is expansible in the form (27), and shall use (28) in conjunction with (25) or (26) for finding the successive values of the v's.

§ 14. *Diurnal Tide.*

Let us first consider the diurnal tides. We have $\mathrm{e}=\mathrm{E}\sin\theta\cos\theta$, $k=1$, and $f=\frac{1}{2}$; then $v_0=-\mathrm{E}\sin\theta\cos\theta$. Hence by (28) and (25)

Diurnal tide.

$$-8lqv_0+4mlv_1=0\text{........................}(29),$$

and therefore $v_1=\dfrac{2q}{m}v_0$. Applying the same theorem a second time, $v_2=(2q/m)v_1$, and so on; therefore $\mathrm{u}=v_0[1+2lq/ma+(2lq/ma)^2+\ldots]$

$$=\frac{v_0}{1-2lq/ma}=-\frac{\mathrm{e}}{1-2lq/ma}\text{..................}(30).$$

But $\mathrm{u}=\mathrm{h}-\mathrm{e}$; hence $\mathrm{h}=-\dfrac{2lq/ma}{1-2lq/ma}\mathrm{e}$ ....(31).

It appears, therefore, that the tide is "inverted," giving low water where the equilibrium tide gives high water. If $q=0$, so that the ocean is of uniform depth, the tide vanishes.

§ 15. *Semi-Diurnal Tide, with Variable Depth.*

Next let us consider the semi-diurnal tide in the case where $q=1$, so that $\gamma=l\sin^2\theta$. Then $\mathrm{e}=\mathrm{E}\sin^2\theta$, $k=2$, $f=1$; also $v_0=-\mathrm{e}=-\mathrm{E}\sin^2\theta$. Hence by (28) and (26) $-8lv_0+4mlv_1=0$, whence $v_1=2/mv_0$. Applying the same theorem a second time, $v_2=(2/m)^2v_0$, and so on; therefore $\mathrm{u}=v_0[1+2l/ma+(2l/ma)^2+\ldots]$

Semi-diurnal tide.

$$=\frac{v_0}{1-2l/ma}=-\frac{\mathrm{e}}{1-2l/ma}.$$

Hence $$\mathrm{h}=\mathrm{u}+\mathrm{e}=-\frac{2l/ma}{1-2l/ma}\mathrm{e}\text{..............}(32).$$

If $2l/ma=\frac{1}{2}$, the height of tide is equal to the equilibrium height; but it is inverted, giving low water where the equilibrium theory gives high water. In the case of the earth $m=1/289$, and therefore this relation is satisfied if $l=a/1156$. Hence in a sea 3000 fathoms deep at the equator, and shallowing to the poles, we have inverted semi-diurnal tides of the equilibrium height.

§ 16. *Semi-Diurnal Tide, with Uniform Depth.*

The method of development used above, where we proceed by powers of the depth of the ocean, is not applicable where the depth is uniform, because it leads to a divergent series. We have therefore to resume equation (24). In the case of the semi-diurnal tides we have for the depth $\gamma=l$ (a constant by hypothesis), $k=2$, $f=1$ approximately, and $\mathrm{e}=\mathrm{E}\sin^2\theta$. Now for brevity let $\beta=4ma/l$, $\nu=\sin\theta$, so that $\mathrm{e}=\mathrm{E}\nu^2$. Then we find that on development (24) becomes

$$\nu^2(1-\nu^2)\frac{d^2\mathrm{u}}{d\nu^2}-\nu\frac{d\mathrm{u}}{d\nu}-(8-2\nu^2-\beta\nu^4)\mathrm{u}=-\beta\mathrm{E}\nu^6\text{...}(33).$$

Let us now assume as the solution of this equation

$$\mathrm{u}=(K_2-\mathrm{E})\nu^2+K_4\nu^4+K_6\nu^6+\ldots+K_{2i}\nu^{2i}+\ldots(34).$$

Substituting from (34) in (33), and equating to zero the coefficients of the successive powers of ν, we find $K_2=E$, K_4 apparently indeterminate, and

$$2i(2i+6)K_{2i+4}-2i(2i+3)K_{2i+2}+\beta K_{2i}=0\text{...}(35).$$

Since $K_0=0$, this equation of condition may be held to apply for all positive integral values of i, beginning with $i=0$. It is obvious that K_6 is determinable in terms of K_4 and K_2, K_8 in terms of K_6 and K_4, etc., so that all the K's are to be found in terms of K_2, which is known, and of K_4, which is apparently indeterminate.

The condition for the convergency of the series (34) for u and for the series $d\mathrm{u}/d\nu$ is that K_{2i+2}/K_{2i} shall tend to a limit less than unity. The equation (35) may be written

$$\frac{K_{2i+4}}{K_{2i+2}}=\frac{2i+3}{2i+6}-\frac{\beta}{2i(2i+6)}\,\frac{K_{2i}}{K_{2i+2}}\text{.........}(36).$$

Now K_{2i+2}/K_{2i} tends to be either infinitely small or not infinitely small. If it be not infinitely small in the limit, the second term on the right of (36) becomes evanescent when i is very great, and we have in the limit when i is very large—

$$\frac{K_{2i+4}\nu^{2i+4}}{K_{2i+2}\nu^{2i+2}}=\frac{2i+3}{2i+6}\nu^2=\left[1-\frac{3}{2(i+3)}\right]\nu^2=\left[1-\frac{3}{2i}\right]\nu^2.$$

But the ratio of successive terms of $\sqrt{(1-\nu^2)}$ tends to become $(1-\frac{3}{2}/i)\nu^2$. Hence, if K_{2i+2}/K_{2i} does not tend to become infinitely small, $\mathrm{u}=\mathrm{A}+\mathrm{B}\sqrt{1-\nu^2}$, where A and B are finite for all values of ν. Again, under the same circumstances we have in the limit when i is very large—

$$\frac{(2i+4)K_{2i+4}\nu^{2i+3}}{(2i+2)K_{2i+2}\nu^{2i+1}}=\frac{2i+4}{2i+2}\cdot\frac{2i+3}{2i+6}\nu^2=\left(1+\frac{1}{i+1}\right)$$
$$\left(1-\frac{3}{2(i+3)}\right)\nu^2=(1-1/2i)\nu^2.$$

But the ratio of successive terms of $(1-\nu^2)^{-\frac{1}{2}}$ tends to $(1-\frac{1}{2}/i)\nu^2$. Hence, if K_{2i+2}/K_{2i} does not tend to become infinitely small, $d\mathrm{u}/d\nu=\mathrm{C}+\mathrm{D}(1-\nu^2)^{-\frac{1}{2}}$, where C and D are finite for all values of ν.

Now $$\frac{d\mathrm{u}}{d\theta}=\frac{d\mathrm{u}}{d\nu}\sqrt{1-\nu^2}=\mathrm{C}\sqrt{1-\nu^2}+\mathrm{D}.$$

Therefore at the equator, where $\nu=1$, $d\mathrm{u}/d\theta=\mathrm{D}$, a finite quantity. Hence the hypothesis that K_{2i+2}/K_{2i} tends to be not infinitely small leads to the conclusion that u and $d\mathrm{u}/d\theta$ are finite at the equator. But on account of the symmetry of the system the co-latitudinal displacement ξ must vanish at the equator, and therefore x also. By (23), when $f=1$, $k=2$, $\nu=\sin\theta$,

$$\nu^2\mathrm{x}=\frac{1}{4m}\left(\frac{d\mathrm{u}}{d\theta}+2\mathrm{u}\cos\theta\right).$$

But we have just seen that this hypothesis makes u finite when $\nu=1$, or $\theta=90°$, and therefore at the equator

$$\mathrm{x}=\frac{1}{4m}\frac{d\mathrm{u}}{d\theta},\text{ a finite quantity.}$$

Now symmetry necessitates a vanishing value of $d\mathrm{u}/d\theta$ at the equator. Thus the hypothesis that K_{2i+2}/K_{2i} tends to be not infinitely small is negatived, and we conclude that, on account of the symmetry of the motion, it is infinitely small for infinitely great values of i. This being established, let us write (36) in the form

$$\frac{K_{2i+2}}{K_{2i}}=\frac{\frac{1}{4}\beta}{2i^2+3i-(2i^2+6i)K_{2i+4}/K_{2i+2}}\quad\text{....(36a).}$$

Hence by repeated application of (36a) we have

$$\frac{K_{2i+2}}{K_{2i}}=\frac{\frac{1}{4}\beta}{2i^2+3i-}\;\frac{(i^2+3i)\beta}{2(i+1)^2+3(i+1)-}\;\frac{[(i+1)^2+3(i+1)]\beta}{2(i+2)^2+3(i+2)}-\text{etc.}\quad(37).$$

Method of continued fraction.

And we know that this is a continuous approximation to K_{2i+2}/K_{2i}, which must hold in order that the latitudinal velocity may vanish at the equator. Writing $N_i=K_{2i+2}/K_{2i}$, all the N's may be computed from the continued fraction (37). Then

$$K_2=\mathrm{E},\ K_4/\mathrm{E}=N_1,\ K_6/\mathrm{E}=N_1N_2,\ K_8/\mathrm{E}=N_1N_2N_3,\text{ etc.}$$

We cannot compute K_6 from K_4, K_8 from K_6, and so on; for, if we do, then, short of infinite accuracy in the numerical values, we shall be gradually led to successive values of the K's which tend to equality.[1]

This process was followed by Laplace without explanation. It was attacked by Airy in his "Tides and Waves" (in *Ency. Metrop.*) and by Ferrel in his *Tidal Researches* (U. S. Coast Survey, 1873), but was justified by Sir W. Thomson in the *Phil. Mag.* (1875, p. 230). The investigation given here is substantially Thomson's.

Solutions.

Laplace gives numerical solutions for three different depths of the sea, $\frac{1}{2890}$, $\frac{1}{722.5}$, $\frac{1}{361.25}$ of the earth's radius. Since $m=\frac{1}{289}$, these correspond respectively to the cases of $\beta=40$, 10, 5, and the solutions are

$$\begin{aligned}\beta=40,\ \mathrm{h}=\mathrm{E}\{&\nu^2+20.1862\nu^4+10.1164\nu^6-13.1047\nu^8-15.4488\nu^{10}\\&-7.4581\nu^{12}-2.1975\nu^{14}-0.4501\nu^{16}-0.0687\nu^{18}\\&-0.0082\nu^{20}-0.0008\nu^{22}-0.0001\nu^{24}\ldots\}\\\beta=10,\ \mathrm{h}=\mathrm{E}\{&\nu^2+6.1960\nu^4+3.2474\nu^6+0.7238\nu^8+0.0919\nu^{10}\\&+0.0076\nu^{12}+0.0004\nu^{14}\ldots\}\\\beta=5,\ \mathrm{h}=\mathrm{E}\{&\nu^2+0.7504\nu^4+0.1566\nu^6+0.0157\nu^8+0.0009\nu^{10}+\ldots\}\end{aligned}$$

Since h vanishes when $\nu=0$, there is no rise and fall of water at the poles. When $\nu=1$ at the equator, we find

$$\begin{aligned}\beta&=40,\ \mathrm{h}=-7.434\ \mathrm{E}\\\beta&=10,\ \mathrm{h}=\ \ 11.267\ \mathrm{E}\\\beta&=\ \ 5,\ \mathrm{h}=\ \ \ 1.924\ \mathrm{E}.\end{aligned}$$

The negative sign in the first case shows that the tide is inverted at the equator, giving low water when the disturbing body is on the meridian. Near the pole, however, that is, for small values of ν, the tides are direct. In latitude 18° (approximately) there is a nodal line of evanescent semidiurnal tide. In the second and third cases the tides are everywhere direct, increasing in magnitude from pole to equator. As β diminishes the tides tend to assume their equilibrium value, because all the terms, save the first, become evanescent. When $\beta=1$ (depth $\frac{1}{72}$ of radius) the tide at the equator still exceeds its equilibrium value by 11 per cent. As β diminishes from 40 to 10 the nodal line of evanescent tide contracts round the pole, and when it is infinitely small the tides are infinitely great. The particular value of β for which this occurs is that where the free oscillation of the ocean has the same period as the forced oscillation. The values chosen by Laplace were not well adapted for the illustration of the results, because in the cases of $\beta=40$ and $\beta=10$ the depth of the ocean is not much different from that value which would give infinite semi-diurnal tide. For values of β greater than 40 we should find other nodal lines dividing the sphere into regions of direct and inverted tides. We refer the reader to Sir W. Thomson's papers for further details on this interesting point.

§ 17. *Tides of Long Period; Laplace's Argument from Friction.*

Laplace's argument from friction unsound.

In treating these oscillations Laplace remarks that a very small amount of friction will be sufficient to cause the surface of the ocean to assume at each instant its form of equilibrium, and he adduces in proof of his conclusion the considerations given below. The friction here contemplated is such that the integral effect is represented by a retarding force proportional to the velocity of the water relatively to the bottom. Although proportionality to the square of the velocity would probably be nearer to the truth, yet Laplace's hypothesis suffices for the present discussion.

In oscillations of this class the water moves for half a period north, and then for half a period south. In oscillating systems, where the resistances are proportional to the velocities, it is usual to specify the resistance by a modulus of decay, namely, that period in which a velocity is reduced to ϵ^{-1} of its initial value by friction. Now the friction contemplated by Laplace is such that the modulus of decay is short compared with the semi-period of oscillation. The quickest of the important tides of long period is the fortnightly (see chapter iv.); hence, for the applicability of Laplace's conclusion, the modulus of decay must be short compared with a week. Now it seems practically certain that the friction of the bed of the ocean would not materially affect the velocity of a slow ocean current in a day or two. Hence we cannot accept Laplace's discussion as satisfactory. However this may be, we now give what is substantially his argument.

Let us write $ϐ$ for the reciprocal of the modulus of decay. Then the frictional forces introduced on the left-hand side of (17) are $+ϐ\,d\xi/dt$ in the first and $\sin\theta\,ϐ\,d\eta/dt$ in the second. Laplace's hypothesis with regard to the magnitude of the frictional forces enables us to neglect the terms $d^2\xi/dt^2$ and $\sin\theta\,d^2\eta/dt^2$ compared with the frictional forces. Then, if we observe that in oscillations of this class the motion is entirely latitudinal, equations (17) and (19) become

$$\left.\begin{aligned}&ϐ\frac{d\xi}{dt}-2n\sin\theta\cos\theta\frac{d\eta}{dt}=-\frac{g}{a}\frac{d}{d\theta}(\mathfrak{h}-\mathfrak{e})\\&\sin\theta\,ϐ\frac{d\eta}{dt}+2n\cos\theta\frac{d\xi}{dt}=0\\&\mathfrak{h}a\sin\theta+\frac{d}{d\theta}(\gamma\xi\sin\theta)=0\end{aligned}\right\}\ \text{...(38).}$$

From the first two of these we easily obtain

$$\left(ϐ+\frac{4n^2}{ϐ^2}\cos^2\theta\right)\frac{d\xi}{dt}=-\frac{g}{a}\frac{d}{d\theta}(\mathfrak{h}-\mathfrak{e})\quad\text{......(39).}$$

As a first approximation we treat $d\xi/dt$ as zero, and obtain $\mathfrak{h}=\mathfrak{e}$ or the height of water satisfies the equilibrium theory. In these tides (see chap. iv.) $\mathfrak{e}=\mathfrak{E}\,(\frac{1}{3}-\cos^2\theta)\cos it$, so that from the third equation of (38) we can obtain a first approximation to ξ; then, substituting in (39), we obtain on integration a second approximation to $\mathfrak{h}$. Laplace, however, considers as adequate the first approximation, which is simply the conclusion of the equilibrium theory.

§ 18. *Tides of Long Period in an Ocean of Uniform Depth.*

Tides of long period without friction.

As it seems certain that these tides do not satisfy even approximately the equilibrium law, we now proceed to find the solution where there is no friction. In the case of these tides $k=0$, f a small fraction, and $\mathrm{e}=\mathrm{E}\,(\frac{1}{3}-\cos^2\theta)$. The equation (24) then becomes

$$\frac{1}{\sin\theta}\frac{d}{d\theta}\left(\frac{\gamma\sin\theta\frac{d\mathrm{u}}{d\theta}}{f^2-\cos^2\theta}\right)+4ma\,(\mathrm{u}+\mathrm{e})=0;$$

or, writing μ for $\cos\theta$ and $\mathrm{e}=\mathrm{E}\,(\frac{1}{3}-\mu^2)$,

$$\frac{d}{d\mu}\left(\gamma\frac{1-\mu^2}{\mu^2-f^2}\frac{d\mathrm{u}}{d\mu}\right)=4ma\,(\mathrm{u}+\mathrm{e})\text{..... . (40).}$$

We shall confine the investigation to the case where $\gamma=l$, a constant, and where the sea covers the whole surface of the globe. The symmetry of the motion in this case demands that u when expanded in a series of powers of μ shall only involve even powers. Let us assume, therefore, that

---

[1] Thomson calls this a dissipation of accuracy. It may be illustrated thus. Consider the equation $x^2-3x+2=0$, which may be written either $x=\frac{2}{3}+\frac{1}{3}x^2$ or $x=3-2/x$. Now let $x_{n+1}=\frac{2}{3}+\frac{1}{3}x^2_n$, and suppose we start with any value x_0, less than unity, and compute x_1, x_2,...x_n. Then, starting with x_n in the equation $x_{n-1}=3-2/x_n$, if we work backwards, we ought to come to the original value x_0. In fact, however, we shall only do so if there is infinite accuracy in all the numerical values. For, start with $x_0=\frac{1}{2}$, then $x_1=.75$, $x_2=.8542$, $x_3=.9099$, $x_4=.9527$, $x_5=.9692$; and the values go on approximating to 1, which is a root of the equation. Next start backwards with $x_5=.97$, and we find $x_4=.938$, $x_3=.868$, $x_2=.696$, $x_1=.127$, $x_0=-12.75$, $x_{-1}=3.157$, $x_{-2}=2.367$, $x_{-3}=2.155$, $x_{-4}=2.072$; and the values go on approximating to 2, the other root of the equation.

$$\frac{1}{\mu^2-f^2}\frac{du}{d\mu}=B_1\mu+B_3\mu^3+\ldots+B_{2i+1}\mu^{2i+1}+\ldots \quad \ldots\ldots(41).$$

Then
$$\frac{1-\mu^2}{\mu^2-f^2}\frac{du}{d\mu}=B_1\mu+(B_3-B_1)\mu^3+\ldots+(B_{2i+1}-B_{2i-1})\mu^{2i+1}+\ldots$$
$$\frac{d}{d\mu}\left(\frac{1-\mu_2}{\mu^2-f^2}\frac{du}{d\mu}\right)=B_1+3(B_3-B_1)\mu^2+\ldots$$
$$+(2i+1)(B_{2i+1}-B_{2i-1})\mu^{2i}+\ldots\ldots\ldots\ldots(42).$$

Again,
$$\frac{du}{d\mu}=-f^2B_1\mu+(B_1-f^2B_3)\mu^3+\ldots+(B_{2i-1}-f^2B_{2i+1})\mu^{2i+1}+\ldots\ldots(43),$$
$$u=C-\tfrac{1}{2}f^2B_1\mu^2+\tfrac{1}{4}(B_1-f^2B_3)\mu^4+\ldots+\frac{1}{2i}(B_{2i-3}-f^2B_{2i-1})\mu^{2i}+\ldots\ldots\ldots(44),$$

where C is a constant. Then, writing β for $4ma/l$, as in the case of the semi-diurnal tide, substituting from (42), (43), and (44) in (40), and equating to zero the successive coefficients of the powers of μ, we find

$$\left.\begin{array}{c} C=-\tfrac{1}{3}E+B_1/\beta \\ B_3-B_1\left(1-\dfrac{1}{2.3}f^2\beta\right)+\tfrac{1}{3}\beta E=0 \\ \cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot\quad\cdot \\ B_{2i+1}-B_{2i-1}\left(1-\dfrac{1}{2i(2i+1)}f^2\beta\right)-\dfrac{\beta}{2i(2i+1)}B_{2i-3}=0 \end{array}\right\}(45).$$

Thus the constant C and B_3, B_5, etc., are all expressible in terms of B_1, and B_1 is apparently indeterminate. We may remark that, if

$$-\frac{\beta}{2.3}B_{-1}=\tfrac{1}{3}\beta E,\text{ or } B_{-1}=-2E,$$

the equation of condition (45) may be held to apply for all values of i, from one to infinity. Let us write (45) in the form

$$\frac{B_{2i+1}}{B_{2i-1}}=1-\frac{1}{2i(2i+1)}f^2\beta+\frac{\beta}{2i(2i+1)}\frac{B_{2i-3}}{B_{2i-1}}\ldots\ldots(46).$$

When i is large B_{2i+1}/B_{2i-1} either tends to become infinitely small or it does not do so. Let us suppose that it does not tend to become infinitely small. Then it is obvious that the successive B's tend to become equal to one another, and so also do the values of $(B_{2i-2}-f^2B_{2i-1})/2i$ and the coefficients of $du/d\mu$. Hence we have $du/d\mu=L+M/(1-\mu^2)$, for all values of μ, where L and M are finite.

Method of continued fraction.

Hence this hypothesis gives infinite velocity to the fluid at the pole, where $\mu=1$. But with a water-covered globe this infinite velocity is impossible, and therefore the hypothesis is negatived, and B_{2i+1}/B_{2i-1} must tend to become infinitely small. This being established, let us write (46) in the form

$$\frac{B_{2i-1}}{B_{2i-3}}=\frac{-\dfrac{\beta}{2i(2i+1)}}{1-\dfrac{f^2\beta}{2i(2i+1)}-\dfrac{B_{2i+1}}{B_{2i-1}}}\quad\ldots\ldots(47).$$

By repeated applications of (47), we have in the form of a continued fraction

$$\frac{B_{2i-1}}{B_{2i-3}}=\cfrac{-\dfrac{\beta}{2i(2i+1)}}{1-\dfrac{f^2\beta}{2i(2i+1)}+\cfrac{\dfrac{\beta}{(2i+2)(2i+3)}}{1-\dfrac{f^2\beta}{(2i+2)(2i+3)}+\cfrac{\dfrac{\beta}{(2i+4)(2i+5)}}{1-\dfrac{f^2\beta}{(2i+4)(2i+5)}+\text{etc.}}}}\ldots\ldots(48).$$

And we know that this is a continuous approximation, which must hold in order to satisfy the condition that the water covers the whole globe. Let us denote this continued fraction by $-N_i$. Then, if we remember that $B_{-1}=-2E$, we have

$$B_1=2EN_1,\ B_3/B_1=-N_2,\ B_5/B_3=-N_3,\ B_7/B_5=-N_4,\text{ etc.},$$

so that

$$B_3=-2EN_1N_2,\ B_5=2EN_1N_2N_3,\ B_7=-2EN_1N_2N_3N_4,\text{ etc.},$$

and
$$C=-\tfrac{1}{3}E+2EN_1/\beta.$$

Then
$$\begin{aligned} h&=u+e\\ &=C+\tfrac{1}{3}E-(E+\tfrac{1}{2}f^2B_1)\mu^2+\tfrac{1}{4}(B_1-f^2B_3)\mu^4+\tfrac{1}{6}(B_3-f^2B_5)\mu^6+\ldots\\ &=E\left\{2N_1/\beta-(1+f^2N_1)\mu^2+\tfrac{1}{2}N_1(1+f^2N_2)\mu^4-\tfrac{1}{3}N_1N_2(1+f^2N_3)\mu^6+\ldots\right\}\ldots\ldots\ldots\ldots(49). \end{aligned}$$

Now we find that, when $\beta=40$, which makes the depth of the sea 3000 fathoms or $\frac{1}{2890}$ of the radius of the earth, and with $f=.0365012$, which is the value for the fortnightly tide (see chap. iv.),

$N_1=3.040692$, $N_2=1.20137$, $N_3=.66744$, $N_4=.42819$, $N_5=.29819$, $N_6=.21950$, $N_7=.16814$, $N_8=.13287$, $N_9=.107$, $N_{10}=.1$.

These values give

$$2N_1/\beta=.15203,\ 1+f^2N_1=1.0041,\ \tfrac{1}{2}N_1(1+f^2N_2)=1.5228,$$
$$\tfrac{1}{3}N_1N_2(1+f^2N_3)=1.2187,\ \tfrac{1}{4}N_1N_2N_3(1+f^2N_4)=.60988,$$
$$\tfrac{1}{5}N_1\ldots N_4(1+f^2N_5)=.20888,\ \tfrac{1}{6}N_1\ldots N_5(1+f^2N_6)=.05190,$$
$$\tfrac{1}{7}N_1\ldots N_6(1+f^2N_7)=.00976,\ \tfrac{1}{8}N_1\ldots N_7(1+f^2N_8)=.0014,$$
$$\tfrac{1}{9}N_1\ldots N_8(1+f^2N_9)=.00017.$$

So that

Solutions.

$$h/e=\{.1520-1.0041\mu^2+1.5228\mu^4-1.2187\mu^6+.6099\mu^8-.2089\mu^{10}+.0519\mu^{12}-.0098\mu^{14}+.0014\mu^{16}-.0002\mu^{18}\}\div(\tfrac{1}{3}-\mu^2)\ldots\ldots\ldots\ldots(50).$$

At the pole, where $\mu=1$, $h=-E\times.1037=e\times.1556$ and at the equator, where $\mu=0$, $h=+E\times.1520=e\times.4561$ ………………………… (51).

Now let us take a second case, where $\beta=10$, which was also one of those solved for the case of the semi-diurnal tide by Laplace, and we find

$$h/E=.2363-1.0016\mu^2+.5910\mu^4-.1627\mu^6+.0258\mu^8-.0026\mu^{10}+.0002\mu^{12}.$$

At the pole, where $\mu=1$, we find $h=-E\times.3137=e\times.471$, and at the equator $h=+E\times.2363=e\times.709$. With a deeper ocean we should soon arrive at the equilibrium value for the tide, for N_1, N_2, etc., become very small, and $2N_1/\beta$ becomes equal to $\frac{1}{3}$. In this case, with such oceans as those with which we have to deal, the tides of long period are considerably smaller that the equilibrium value.

§ 19. *Stability of the Ocean.*

Stability of the ocean.

Imagine a globe of density δ, surrounded by a spherical layer of water of density σ. Then, still maintaining the spherical figure, and with water still covering the nucleus, let the layer be displaced sideways. The force on any part of the water distant r' from the centre of the water and r from the centre of the nucleus is $\frac{4}{3}\pi\sigma r'$ towards the centre of the fluid sphere and $\frac{4}{3}\pi(\delta-\sigma)r$ towards the centre of the nucleus. If δ be greater than σ there is a force tending to carry the water from places where it is deeper to places where it is shallower; and therefore the equilibrium, thus arbitrarily disturbed, is stable. If, however, δ is less than σ (or the nucleus lighter than water) the force is such that it tends to carry the water from where it is shallower to where it is deeper, and therefore the equilibrium of a layer of fluid distributed over a nucleus lighter than itself is unstable. As Sir William Thomson has remarked,[1] if the nucleus is lighter than the ocean, it will float in the ocean with part of its surface dry. Suppose, again, that the fluid layer be disturbed, so that its equation is $r=a(1+s_i)$, where s_i is a surface harmonic of degree i; then the potential due to this deformation is $\frac{4\pi\sigma}{2i+1}\frac{a^{i+3}}{r^{i+1}}s_i$, and the whole potential is

Stabilities of various orders.

$$\frac{4\pi\delta a^3}{3r}+\frac{4\pi\sigma}{2i+1}\frac{a^{i+3}}{r^{i+1}}s_i.$$

If, therefore, $\sigma/(2i+1)$ is greater than $\frac{1}{3}\delta$, the potential of the forces due to deformation is greater than that due to the nucleus. But we have seen that a deformation tends to increase itself by mutual attraction, and therefore the forces are such as to increase the deformation. If, therefore, $\sigma=\frac{1}{3}(2i+1)\delta$, all the deformations up to the ith are unstable, but the $i+1$th is stable.[2] If, however, σ be less than δ, then all the deformations of any order are such that there are positive forces of restitution. For our present purpose it suffices that this equilibrium is stable when the fluid is lighter than the nucleus.

§ 20. *Precession and Nutation.*

Precession and nutation.

Suppose we have a planet covered with a shallow ocean, and that the ocean is set into oscillation. Then, if there are no external disturbing forces, so that the oscillations are "free," not "forced," the resultant moment of momentum of the planet and ocean remains constant. And, since each particle of the ocean executes periodic oscillations about a mean position, it follows that the oscillation of the ocean imparts to the solid earth oscillations such that the resultant moment of momentum of the whole system remains constant. But the mass of the ocean being very small compared with that of the planet, the component angular velocities of the planet necessary to counterbalance the moment of momentum of the oscillations of the sea are very small compared with the component angular velocities of the sea, and therefore the disturbance of planetary rotation due to oceanic reaction is negligible. If now an external disturbing force, such as that of the moon, acts on the system, the resultant moment of momentum of sea and earth is unaffected by the interaction between them, and the precessional and nutational couples are the same as if sea and earth were rigidly connected together. Therefore the additions to these couples on account of tidal oscillation are the couples due to the attraction of the moon on the excess or deficiency of water above or below mean sea-level. The tidal oscillations are very small in height compared with the equatorial protuberance of the earth, and the density of water is $\frac{4}{11}$ths of that of surface rock; hence the additional couples are very small compared with the couples due to the moon's action on the solid equatorial protuberance. Therefore precession and nutation take place sensibly as though the sea were congealed in its mean position. If the ocean be regarded as frictionless, the principles of energy show us that these insensible additional couples must be periodic in time, and thus the corrections to nutation must consist of semi-diurnal, diurnal, and fortnightly nutations of absolutely insensible magnitude. We shall have much to say below on the results of the introduction of friction into the conception of tidal oscillations as a branch of speculative astronomy.

Corrections to precession and nutation insensible.

§ 21. *Some Phenomena of Tides in Rivers.*

Tides in rivers.

In § 2 we have given a description of some of the phenomena of the tide-wave in rivers. As a considerable part of our practical knowledge of tides is derived from observations in estuaries and rivers, we give an investigation of two of the most important features of the tide-wave in these cases. It must be premised that when the profile of a wave does not present the simple harmonic form it is convenient to analyze its shape into a series of partial waves superposed on a fundamental wave; and generally the principle of harmonic analysis is adopted, in which the actual wave is regarded as the sum of a number of simple harmonic waves.

The tide-wave in a river is a "long" wave in which the vertical motion of the water is very small compared with the horizontal, the river very shallow compared with the wave-length, and the water which is at any moment in a vertical plane always remains so throughout the oscillation.

Suppose that the water is contained in a straight and shallow canal of uniform depth; then take an origin of coordinates at the bottom, with the x axis horizontal in the direction of the canal, and the y axis vertical; let h be the undisturbed depth of water; let $h+\eta$ be the ordinate of the surface corresponding to that fluid whose undisturbed abscissa is x and disturbed abscissa $x+\xi$; and let g be gravity. The equations of motion and continuity[1] are

$$\left.\begin{aligned}\frac{d^2\xi}{dt^2} &= gh\,\frac{d^2\xi/dx^2}{(1+d\xi/dx)^3}\\ \eta &= \frac{-hd\xi/dx}{1+d\xi/dx}\end{aligned}\right\} \text{..............(52).}$$

For brevity we shall write $v^2=gh$ and $u=vt-x$. Since for "long" waves $d\xi/dx$ is small, the equations (52) become approximately

$$\left.\begin{aligned}\frac{d^2\xi}{dt^2} &= v^2\,\frac{d^2\xi}{dx^2}\left(1-3\frac{d\xi}{dx}\right)\\ \frac{\eta}{h} &= -\frac{d\xi}{dx}+\left(\frac{d\xi}{dx}\right)^2\end{aligned}\right\} \text{..............(53).}$$

For finding a first approximation we neglect the second term on the right of each of (53). The solution is obviously

$$\left.\begin{aligned}\xi &= a\cos m(vt-x) = a\cos mu\\ \eta &= -mah\sin mu\end{aligned}\right\} \text{............(54).}$$

(54) gives the height of the water whose undisturbed abscissa is x, and since ξ is small this is approximately the height at the point on the bank whose abscissa is x. But now suppose that at the origin (the mouth of the river) the canal communicates with a basin in which there is a forced oscillation of water-level given by

$$\eta = H\sin nt \text{.........................(55).}$$

This represents the oceanic tide, and n is that which we call below (§ 23) the speed of the tide. Then obviously $m=n/v$, so that at any point x up the river

$$\eta = H\sin n\left(t-\frac{x}{\sqrt{gh}}\right) \text{...............(56).}$$

(56) gives the first approximation to the forced tide-wave, and it is clear that any number of oscillations may be propagated independently up the river with the velocity $\sqrt{gh}$ due to the depth of the river. In passing to the second approximation we must separate the investigation into two branches.

Over-tides.

(i.) *Over-Tides* (see § 24).—We now suppose that the tide at the river mouth is simply (55). On substituting the approximate values (54) in (53) our equations become

$$\left.\begin{aligned}\frac{d^2\xi}{dt^2} &= v^2\,\frac{d^2\xi}{dx^2}+\tfrac{3}{2}v^2a^2m^3\sin 2mu\\ \frac{\eta}{h} &= -\frac{d\xi}{dx}+\tfrac{1}{2}m^2a^2-\tfrac{1}{2}m^2a^2\cos 2mu\end{aligned}\right\} \text{............(57).}$$

We have now to assume an appropriate form for the solution of (57), such as

$$\xi = a\cos mu + \mathrm{A}x\cos 2mu + \mathrm{B}\sin 2mu \text{............(58).}$$

We have here in effect assumed that the second and third terms of (58) are small compared with the first. It is clear, however, that at a distance from the origin the term in A will become large. This difficulty may be eluded by taking the canal of finite length, and supposing that, where the canal debouches into a second basin, a second appropriate forced oscillation is maintained. The length of the canal remains arbitrary, save that the second term of (58) shall still be small compared with the first. On substituting from (58) in (57) we have B indeterminate and $\mathrm{A}=-\tfrac{3}{8}a^2m^2$; hence

$$\begin{aligned}\eta/h = {}&\tfrac{1}{2}m^2a^2 - ma\sin mu + \tfrac{3}{4}m^3a^2x\sin 2mu\\ &+(2m\mathrm{B}-\tfrac{1}{8}m^2a^2)\cos 2mu \text{..........(59).}\end{aligned}$$

This gives the elevation of the water whose undisturbed abscissa is x, that is to say, at the point whose abscissa along the bank is $X=x+\xi$. If we put $x=X-\xi$ in the largest term of (59), and treat ξ as small, and put $x=X$ in the small terms (59) becomes

$$\begin{aligned}\eta/h = {}&-ma\sin m(vt-X)+\tfrac{3}{4}m^3a^2X\sin 2m(vt-X)\\ &+(2m\mathrm{B}-\tfrac{5}{8}m^2a^2)\cos 2m(vt-X).\end{aligned}$$

But at the origin (55) holds true, therefore $\mathrm{B}=\frac{5}{16}ma^2$,—$mah=H$, and $mv=n$. Thus the solution is

$$\eta = H\sin n\left(t-\frac{X}{\sqrt{gh}}\right)+\frac{3H^2n}{4h\sqrt{gh}}X\sin 2n\left(t\,\frac{X}{\sqrt{gh}}\right) \text{...(60).}$$

From (60) we can see what the proper forced oscillation at the further end of the canal must be; but this matter has no present interest. The first term of (60) being called the fundamental, the second gives what is called the first over-tide; and by further approximation we can get the second, third, etc. The over-tide travels up the river at the same rate as the fundamental, but it has double frequency or "speed," and the ratio of its amplitude to that of the fundamental is $\frac{3H}{4h}\,\frac{nX}{\sqrt{gh}}$.

Solution giving first over-tide.

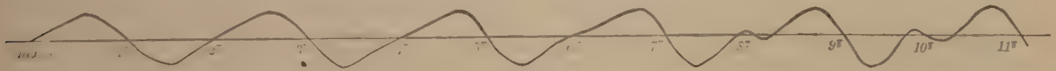

FIG. 1.

As a numerical example, let the range of tide at the river mouth be 20 feet and the depth of river 50 feet. The "speed" of the semi-diurnal tide is about 1/1.9 radians per hour; $\sqrt{gh}=27$ miles per hour; hence $\frac{3H}{4h}\,\frac{nX}{\sqrt{gh}}=\frac{1}{342}X$. Therefore 34 miles up the river the over-tide is $\frac{1}{10}$th of the fundamental and has a range of 2 feet. If the river shallows very gradually, the formula will still hold, and we see that the height of over-tide varies as $(\text{depth})^{-\frac{3}{2}}$.

Fig. 1[2] read from left to right exhibits the progressive change of shape. The steepness of the advancing crest shows that it is a shorter time from low to high water than *vice versa*. The law of the ebb and flow of currents mentioned in § 2 may also be easily determined from the above investigation. We leave the reader to determine the effect of friction, which is given by inserting a term $-\mu d\xi/dt$ on the right-hand side of (57).

---

[1] See, for example, Lamb's *Hydrodynamics*, chap. vii.

[2] From Airy, "Tides and Waves."

Interference of waves in shallow water.

(ii.) *Compound Tides* (see § 24).—We shall now consider the mutual influence of two waves of different periods travelling up the river together. In the first approximation they are quite independent, and we may assume

$$\xi = a \cos m(vt - x) + b \cos [n(vt - x) + \epsilon] \ldots\ldots (61).$$

In proceeding to the second approximation, we only take notice of those terms which result from the interaction of the two, and omit all others, writing for the sake of brevity

$$\begin{aligned} \{ m - n \} &= (m-n)(vt - x) - \epsilon, \\ \{ m + n \} &= (m+n)(vt - x) + \epsilon. \end{aligned}$$

With the value of ξ assumed in (61), we find, on substituting in (53) and only retaining terms depending on mutual influence, that the equations for the second approximation are

$$\left.\begin{aligned} &\frac{d^2\xi}{dt^2} = v^2 \frac{d^2\xi}{dx^2} + \tfrac{3}{2}v^2 abmn[(m+n) \sin \{ m+n \} - (m-n) \\ &\quad \sin \{ m-n \}]\ \eta/h = -abmn[\cos \{ m+n \} - \cos \\ &\quad \{ m-n \}] - d\xi/dx \end{aligned}\right\} (62).$$

Now let us assume as the solution

$$\left.\begin{aligned} \xi = a \cos m(vt - x) + \mathrm{A}x \cos \{ m+n \} + \mathrm{B} \sin \{ m+n \} \\ + b \cos[n(vt - x) + \epsilon + \mathrm{C}x \cos \{ m-n \} + \mathrm{D} \sin \{ m-n \} \end{aligned}\right\} (63).$$

and let us elude the difficulty about the increasing magnitude of the second term in the same way as before. Substituting in the equation of motion, we have for all time,

$$\begin{aligned} &2(m+n)\mathrm{A} \sin \{ m+n \} + 2(m-n)\mathrm{C} \sin \{ m-n \} \\ &+ \tfrac{3}{2}abmn[(m+n) \sin \{ m+n \} - (m-n) \sin \{ m-n \}] = 0. \end{aligned}$$

This gives $\mathrm{A} = -\tfrac{3}{4}abmn$ and $\mathrm{C} = +\tfrac{3}{4}abmn$. B and D remain arbitrary as before, and will be dropped, because they are to be determined by the condition that at the origin the terms of $d\xi/dx$ in $\cos \{ m+n \}$, $\cos \{ m-n \}$ are to vanish, whence

$$\begin{aligned} \eta/h = &-am \sin m(vt - x) - bn \sin [n(vt - x) + \epsilon] \\ &+ \tfrac{3}{4}abmn[(m+n)x \sin \{ m+n \} - (m-n)x \sin \{ m-n \}] \\ &+ \text{terms in } \cos \{ m+n \} \text{ and } \cos \{ m-n \}. \end{aligned}$$

Then we pass from x to X as in the last section, and make the terms in $\cos \{ m+n \}$ and $\cos \{ m-n \}$ vanish by proper values of B and D, and we have

$$\begin{aligned} \eta = &\ amh \sin m(vt - X) - bnh \sin [n(vt - x) + \epsilon] \\ &+ \tfrac{3}{4}abmnX [(m+n) \sin \{ m+n \} - \\ &\qquad (m-n) \sin \{ m-n \}] \ldots\ldots\ldots (64). \end{aligned}$$

Solutions for compound tides.

Now at the river's mouth, where $x = 0$, suppose that the oceanic tide is represented by $\eta = H_1 \sin n_1 t + H_2 \sin (n_2 t + \epsilon)$.

Then $-am = H_1/h$, $-bn = H_2/h$, $habmn = H_1 H_2/h$,

$$mv = n_1, \quad nv = n_2, \quad v = \sqrt{gh}, \quad m \pm n = \frac{n_1 \pm n}{\sqrt{gh}},$$

so that (64) becomes

$$\begin{aligned} \eta = &H_1 \sin n_1\left(t - \frac{X}{\sqrt{gh}}\right) + H_2 \sin\left[n_2\left(t - \frac{X}{\sqrt{gh}}\right) + \epsilon \right] \\ &+ \frac{3H_1H_2}{4h}\frac{n_1 + n_2}{\sqrt{gh}}X \sin\left[(n_1 + n_2)\left(t - \frac{X}{\sqrt{gh}}\right) + \epsilon \right] \\ &- \frac{3H_1H_2}{4h}\frac{n_1 - n_2}{\sqrt{gh}}X \sin\left[(n_1 - n_2)\left(t - \frac{X}{\sqrt{gh}}\right) - \epsilon \right] (65). \end{aligned}$$

As a numerical example, suppose at the mouth of a river 50 feet deep that the solar semi-diurnal tide has a range $2H_1 = 4$ feet, and the lunar $2H_2 = 12$ feet; then $n_1 + n_2 = \frac{59}{57}$ radians per hour, $n_1 - n_2 = \frac{1}{57}$ radians per hour, and as before $\sqrt{gh} = 27$ miles per hour. With these figures

$$\frac{3H_1H_2}{4h}\frac{n_1 + n_2}{\sqrt{gh}}X = \frac{1}{170}X.$$

Thus 15 miles up the river the quater-diurnal tide (in § 24 below, called MS) has a semi-range of an inch. But the luni-solar fortnightly tide (called MSf in § 24) would have a semi-range of $\frac{1}{60}$th of an inch. Where the two interacting tides are of nearly equal speed, the summation compound tide is very large compared with the differential tide. As before, when the river shallows gradually this formula will still hold.

It is interesting to note the kind of effect produced by these compound tides. When the primary tides are in the same phase

$$n_1 t = n_2 t + \epsilon.$$

Then
$$\begin{aligned} (n_1 + n_2)\left(t - \frac{X}{\sqrt{gh}}\right) + \epsilon &= 2n_1 t - (n_1 + n_2)\frac{X}{\sqrt{gh}}; \\ (n_1 - n_2)\left(t - \frac{X}{\sqrt{gh}}\right) - \epsilon &= -(n_1 - n_2)\frac{X}{\sqrt{gh}}; \end{aligned}$$

and

$$\begin{aligned} \eta = &H_1 + H_2 \sin n_1\left(t - \frac{X}{\sqrt{gh}}\right) + \frac{3H_1H_2}{4h}\frac{n_1 + n_2}{\sqrt{gh}} \sin \left[2n_1 t \right. \\ &\left. - (n_1 + n_2)\frac{X}{\sqrt{gh}} \right] - \frac{3H_1H_2}{4h}\frac{n_1 - n_2}{\sqrt{gh}} \sin \frac{(n_1 - n_2)}{\sqrt{gh}}X. \end{aligned}$$

Hence the front slope of the tide-wave is steeper at spring than at neap tide, and the compound tide shows itself in the form of an augmentation of the first over-tide; and the converse statements hold of neap tide. Also mean-water mark is lower and higher alternately up the river at spring tide, and higher and lower at neap tide, by a small amount which depends on the differential tide. With the river which we were considering, the alternation would be so long that it would in actuality be either all lower or all higher.

IV. THE HARMONIC ANALYSIS.

§ 22. *Methods of applying Theory to Practice.*

Two methods of treating observations.

The comparison between tidal observations and tidal theories, and the formation of tables predicting the tidal oscillations of the sea, have been carried out in two different ways, which may be called the "synthetic" and the "analytic."

Synthetic method.

The semi-diurnal rise and fall of tide with the weekly alternation of spring and neap would naturally suggest to the investigator to make his formula conform to the apparent simplicity of the phenomenon. He would seek to represent the height of water by either one or two periodic functions with a variable amplitude; such a representation is the aim of the synthetic method. That method has been followed by all the great investigators of the past,—Newton, Bernoulli, Maclaurin, Laplace, Lubbock, Whewell, Airy. Since at European ports the two tides which follow one another on any one day are nearly equal, or, in other words, there is scarcely a sensible diurnal tide, these investigators bestowed comparatively little attention to the diurnal tides. If these are neglected, the synthetic method is simple, for a single function suffices to represent the tide. In non-European ports, however, the diurnal tide is sometimes so large as to mask the semi-diurnal, and to make only a single instead of a double high water in twenty-four hours. To represent this diurnal tide in the synthetic method we are compelled to introduce at least one more function. There should also be a third function representing the tides of long period; but until the last few years these tides have scarcely been considered, and therefore we shall have little to say of them in explaining the synthetic method. The expression for the tide-generating forces due to either sun or moon consists of three terms, involving the declinations and hour-angles of the planet. One of these terms for each goes through its period approximately twice a day, a second once a day, and the third varies slowly (§ 7). The mathematical basis of the synthetic method consists of a synthesis of the mathematical formulæ. The semi-diurnal term for the moon is fused with that for the sun, and the same process is carried out for the diurnal and slowly varying terms. A mass of tidal observation at a place where the diurnal tide is small, even if, as in all the older observations, it consists merely of heights and times of high and low water, soon shows that the fusion of two simple harmonic or periodic functions is insufficient to represent the state of tide; and the height and time of high water are found to need corrections for the variations of declination, of motion in right ascension, and of the parallaxes of both bodies.

Three classes of tides.

Analytic method.

But when continuous tide-gauges were set up far more extended data than those of the older observations became accessible to the investigator, and more and more corrections were found to be expedient to adapt the formulæ to the facts. A systematic method of utilizing all the data became also a desideratum. This state of matters led Sir W. Thomson to suggest the analytic method.[1] It is true that the dynamical foundations of that method have always lain below the surface of the synthetic method, and have constantly been appealed to for the theoretical determination of corrections; nevertheless, we must regard the explicit adoption of the analytic method as a great advance. In this method we conceive the tidal forces or potential due to each disturbing body to be developed into a series of terms each consisting of a constant (determined by the elements of the planet's orbit and the obliquity of the ecliptic) multiplied by a simple harmonic function of the time. Thus in place of the terms of the synthetic method for the three classes of tides we have an indefinitely long series of terms for each of the three classes. The loss of simplicity in the expression for the forces is far more than counterbalanced by the gain of facility for the discussion of the oscillations of the water. This facility arises from the great dynamical principle of forced oscillations, which we have explained in the historical sketch. Applying this principle, we see that each individual term of the harmonic development of the tide-generating forces corresponds to an oscillation of the sea of the same period, but the amplitude and phase of that oscillation must depend on a network of causes of almost inextricable complication. The analytic method, then, represents the tide at any port by a series of simple harmonic terms whose period is determined from theoretical considerations, but whose amplitude and phase are found from observation. Fortunately the series representing the tidal forces converges with sufficient rapidity to permit us to consider only a moderate number of harmonic terms in the series.

---

[1] Airy, and after him Chazallon, appear to have been amongst the first to use a kind of harmonic analysis for reducing tidal observations; but, as Airy did not emancipate himself from the use of hour-angles, declinations, etc., his work can hardly be considered as an example of the analytic method; see his "Tides and Waves," and Hatt's *Phénomène des Marées*, Paris, 1885.

Now it seems likely that the corrections which have been applied in the use of the synthetic method might have been clothed in a more satisfactory and succinct mathematical form had investigators first carried out the harmonic development. In this article we shall therefore invert history and come back on the synthetic method from the analytic, and shall show how the formulæ of correction stated in harmonic language may be made comparable with them in synthetic language. One explanation is expedient before proceeding with the harmonic development. There are certain terms in the tide-generating forces of the moon, depending on the longitude of the moon's nodes, which complete their revolution in 18.6 years. Now it has been found practically convenient, in the application of the harmonic method, to follow the synthetic plan to the extent of classifying together terms whose speed differs only in consequence of the movement of the moon's node, and at the same time to conceive that there is a small variability in the intensity of the generating forces.

Fusion of terms affected by motion of moon's node.

§ 23. *Development of Equilibrium Theory of Tides in Terms of the Elements of the Orbits.*

Within the limits at our disposal we cannot do more than indicate the processes to be followed in this development.

Equilibrium theory; elements or orbits introduced.

We have already seen in (3) that the expression for the moon's tide-generating potential is

$$V = \frac{3m}{2r^3}\rho^2(\cos^2 z - \tfrac{1}{3}),$$

and in (10) that

$$\cos^2 z - \tfrac{1}{3} = 2\xi\eta M_1M_2 + 2\frac{\xi^2-\eta^2}{2}\cdot\frac{M_1^2-M_2^2}{2} + 2\eta\zeta M_2M_3$$
$$+ 2\xi\zeta M_1M_3 + \frac{3}{2}\,\frac{\xi^2+\eta^2-2\zeta^2}{3}\cdot\frac{M_1^2+M_2^2-2M_3^2}{3},$$

where M_1, M_2, M_3 are the direction cosines of the moon referred to axes fixed in the earth. We require to find the functions M_1M_2, $\frac{1}{2}(M_1^2-M_2^2)$, etc., of the moon's direction cosines.[1] Let A, B, C (Fig. 2) be the axes fixed in the earth, C being the north pole and AB the equator; let X, Y, Z be a second set of axes, XY being the plane of the moon's orbit; M the projection of the moon in her orbit; I = ZC, the obliquity of the lunar orbit to the equator; χ = AX = BCY; l = MX, the moon's longitude in her orbit measured from X, the intersection of the equator with the lunar orbit, hereafter called the "intersection." Then

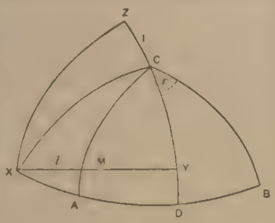

FIG. 2.

Moon's longitude and obliquity of orbit introduced.

$$\left.\begin{aligned} M_1 &= \cos l\cos\chi + \sin l\sin\chi\cos I \\ M_2 &= -\cos l\sin\chi + \sin l\cos\chi\cos I \\ M_3 &= \sin l\sin I \end{aligned}\right\} \quad\ldots(66).$$

Writing for brevity $p = \cos\frac{1}{2}I$, $q = \sin\frac{1}{2}I$ ....(67), we find that

$$\left.\begin{aligned} M_1^2 - M_2^2 &= p^4\cos 2(\chi - l) + 2p^2q^2\cos 2\chi \\ &\quad + q^4\cos 2(\chi + l) \\ -2M_1M_2 &= \text{the same with sines in place of cosines} \\ M_2M_3 &= -p^3q\cos(\chi - 2l) + pq(p^2 - q^2)\cos\chi \\ &\quad + pq^3\cos(\chi + 2l) \\ M_1M_3 &= \text{the same with sines in place of cosines} \\ \tfrac{1}{3} - M_3^2 &= \tfrac{1}{3}(p^4 - 4p^2q^2 + q^4) + 2p^2q^2\cos 2l \end{aligned}\right\} \quad (68).$$

These are the required functions of M_1, M_2, M_3.

Now let c be the moon's mean distance, e the eccentricity of the moon's orbit, and let

$$\tau = \frac{3m}{2c^3} \quad\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (69).$$

Then, putting

$$X = \left[\frac{c(1-e^2)}{r}\right]^{\frac{3}{2}}M_1,\quad Y = \left[\frac{c(1-e^2)}{r}\right]^{\frac{3}{2}}M_2,$$
$$Z = \left[\frac{c(1-e^2)}{r}\right]^{\frac{3}{2}}M_3 \ldots\ldots\ldots\ldots\ldots\ldots (70),$$

we have

$$V = \frac{\tau}{(1-e^2)^3}\rho^2 = 2\xi\eta XY + 2\frac{\xi^2-\eta^2}{2}\cdot\frac{X^2-Y^2}{2} + 2\eta\zeta YZ$$
$$+ 2\xi\zeta XZ + \frac{3}{2}\,\frac{\xi^2+\eta^2-2\zeta^2}{3}\,\frac{X^2+Y^2-2Z^2}{3} \quad\ldots\ldots (71).$$

Corresponding to the definition of a simple tide given in § 1, the expression for each term of the tide-generating potential should consist of a solid spherical harmonic, multiplied by a simple time-harmonic. In (71) $\rho^2\xi\eta$, $\rho^2(\xi^2-\eta^2)$, etc., are solid spherical harmonics, and in order to complete the expression for V it is necessary to develop the five functions of X, Y, Z in a series of simple time-harmonics. But (71) may be simplified in such a way that the five functions are reduced to three. The axes fixed in the earth may be taken, as in § 7, to have their extremities as follows: the axis C the north pole, the axis B 90° E. of A on the equator, and the axis A on the equator in the meridian of the place of observation. Thus, if λ be the latitude of that place, we have

Moon's distance and eccentricity introduced.

$$\xi = \cos\lambda,\ \eta = 0,\ \zeta = \sin\lambda.$$

Then, writing a for the earth's radius at the place of observation, (71) becomes

$$V = \frac{\tau a^2}{(1-e^2)^3}\left[\tfrac{1}{2}\cos^2\lambda(X^2 - Y^2) + \sin 2\lambda\, XZ\right.$$
$$\left. + \tfrac{3}{2}(\tfrac{1}{3} - \sin^2\lambda)\tfrac{1}{3}(X^2 + Y^2 - 2Z^2)\right] \ldots\ldots\ldots (71a).$$

The process of developing the three functions of X, Y, Z consists in the introduction of the formulæ of elliptic motion into (66) and (70), the subsequent development of the X-Y-Z functions in a series of trigonometrical terms, and the rejection of terms which appear numerically to be negligible. The terms depending on the principal lunar inequalities—evection and variation—are also introduced. Finally, the three X-Y-Z functions are obtained as a series of simple time-harmonics, with the arguments of the sines and cosines linear functions of the earth's rotation, the moon's mean motion, and the longitude of the moon's perigee. The next step is to pass, according to the principle of forced oscillations, from the potential to the height of tide generated by the forces corresponding to that potential. The X-Y-Z functions being simple time-harmonics, the principle of forced vibrations allows us to conclude that the forces corresponding to V in (71a) will generate oscillations in the ocean of the same periods and types as the terms in V, but of unknown amplitudes and phases. Now let $\mathfrak{X}^2 - \mathfrak{Y}^2$, $\mathfrak{X}\mathfrak{Z}$, $\frac{1}{3}(\mathfrak{X}^2 + \mathfrak{Y}^2 - 2\mathfrak{Z}^2)$ be three functions having respectively similar forms to those of

Tide-generating potential.

$$\frac{X^2 - Y^2}{(1-e^2)^3},\quad \frac{XZ}{(1-e^2)^3},\quad\text{and}\ \frac{1}{3}\,\frac{(X^2 + Y^2 - 2Z^2)}{(1-e^2)^3},$$

but differing from them in that the argument of each of the simple time-harmonics has some angle subtracted from it, and that the term is multiplied by a numerical factor. Then, if g be gravity and h the height of tide at the place of observation, we must have

Height of tide at any port.

$$h = \frac{\tau a^2}{g}\left[\tfrac{1}{2}\cos^2\lambda(\mathfrak{X}^2 - \mathfrak{Y}^2) + \sin 2\lambda\,\mathfrak{X}\mathfrak{Z}\right.$$
$$\left. + \tfrac{3}{2}(\tfrac{1}{3} - \sin^2\lambda)\tfrac{1}{3}(\mathfrak{X}^2 + \mathfrak{Y}^2 - 2\mathfrak{Z}^2)\right] \ldots\ldots\ldots (72).$$

The factor $\tau a^2/g$ may be more conveniently written $\frac{3m}{2M}\left(\frac{a}{c}\right)^3 a$, where M is the earth's mass. It has been so chosen that, if the equilibrium theory of tides were fulfilled, with

---

[1] For further details of the analysis of this section, see the *Report* "On Harmonic Analysis, etc.," for 1883 to the British Association (Southport).

Definition of high tide of tide of long period.

water covering the whole earth, the numerical factors in the $\mathfrak{X}$-$\mathfrak{Y}$-$\mathfrak{Z}$ functions would be each unity and the alterations of phase would be zero. The terms in $\frac{1}{3}(\mathfrak{X}^2+\mathfrak{Y}^2-2\mathfrak{Z}^2)$ require special consideration. The function of the latitude being $\frac{1}{3}-\sin^2\lambda$, it follows that, when in the northern hemisphere it is high water north of a certain critical latitude, it is low water on the opposite side of that parallel; and the same is true of the southern hemisphere. It is best to adopt a uniform system for the whole earth, and to regard high tide and high water as consentaneous in the equatorial belt, and of opposite meanings outside of the critical latitudes. We here conceive the function always to be written $\frac{1}{3}-\sin^2\lambda$, so that outside of the critical latitudes high tide is low water. We may in continuing the development write the $\mathfrak{X}$-$\mathfrak{Y}$-$\mathfrak{Z}$ functions in the form appropriate to the equilibrium theory, with water covering the whole earth; for the actual case it is only then necessary to multiply by the reducing factor, and to subtract the phase alteration κ. As these are unknown constants for each place, they would only occur in the development as symbols of quantities to be deduced from observation. It will be understood, therefore, that in the following schedules the "argument" is that part of the argument which is derived from theory, the true complete argument being the "argument" $-\kappa$, where κ is derived from observation.

Up to this point we have supposed the moon's longitude and the earth's position to be measured from the intersection; but in order to pass to the ordinary astronomical formulæ we must measure the longitude and the earth's position from the vernal equinox. Hence we determine the longitude and right ascension of the intersection in terms of the longitude of the moon's node and the inclination of the lunar orbit, and introduce them into our formulæ for the $\mathfrak{X}$-$\mathfrak{Y}$-$\mathfrak{Z}$ functions. The expressions for the functions corresponding to solar tides may be written down by symmetry, and in this case the intersection is actually the vernal equinox.

Explanation of schedules below.

The final result of the process sketched is to obtain a series of terms each of which is a function of the elements of the moon's or sun's orbit, and a function of the terrestrial latitude of the place of observation, multiplied by the cosine of an angle which increases uniformly with the time. We shall now write down the result in the form of a schedule; but we must first state the notation employed: e, $e_{\prime}$ = eccentricities of lunar and solar orbits; I, ω = obliquities of equator to lunar orbit and ecliptic; p, $p_{\prime}$ = longitudes of lunar and solar perigees; ϖ, $\varpi_{\prime}$ = hourly increments of p, $p_{\prime}$; s, h = moon's and sun's mean longitudes; σ, η = hourly increments of s, h; t = local mean solar time reduced to angle; $\gamma-\eta=15°$ per hour; λ = latitude of place of observation; ξ, ν = longitude in lunar orbit, and R.A. of the intersection; N = longitude of moon's node; i = inclination of lunar orbit.

Speed defined.

The speed of any tide is defined as the rate of increase of its argument, and is expressible, therefore, as a linear function of γ, η, σ, ϖ; for we may neglect $\varpi_{\prime}$ as being very small.

The following schedules, then, give h the height of tide. The arrangement is as follows: First, there is a universal coefficient $\frac{3m}{2M}\left(\frac{a}{c}\right)^3 a$, which multiplies every term of all the schedules. Secondly, there are general coefficients, one for each schedule, viz., $\cos^2\lambda$ for the semi-diurnal terms, $\sin 2\lambda$ for the diurnal, and $\frac{1}{2}-\frac{3}{2}\sin^2\lambda$ for the terms of long period. In each schedule the third column, headed "coefficient," gives the functions of I and e (and in two cases also of p). In the fourth column is given the mean semi-range of the corresponding term in numbers, which is approximately the value of the coefficient in the first column when $I=\omega$; but we pass over the explanation of the mode of computing the values. The fifth column contains arguments, linear functions of t, h, s, p, ν, ξ. In [A, i.] $2t+2(h-\nu)$ and in [A, ii.] $t+(h-\nu)$ are common to all the arguments. The arguments are grouped in a manner convenient for subsequent computation. Lastly, the sixth is a column of speeds, being the hourly increase of the arguments in the preceding column, estimated in degrees per hour. It has been found practically convenient to denote each of these partial tides by an initial letter, arbitrarily chosen. In the first column we give a descriptive name for the tide, and in the second the arbitrarily chosen initial. In some cases no initial has been chosen, and here we indicate the tide by the analytical expression for its speed, or hourly increase of argument.

The schedule for the solar tides is drawn up in precisely the same manner, the only difference being that the coefficients are absolute constants. The eccentricity of the solar orbit is so small that the elliptic tides may be omitted, except the larger elliptic semi-diurnal tide. In order that the comparison of the importance of the solar tides with the lunar may be complete, the same universal coefficient $\frac{3m}{2M}\left(\frac{a}{c}\right)^3 a$ is retained, and the special coefficient for each term is made to involve the factor $\frac{\tau_{\prime}}{\tau}$. Here $\tau_{\prime}=\frac{3}{2}\frac{m_{\prime}}{c_1{}^3}$, $m_{\prime}$ being the sun's mass. With

$$\frac{M}{m}=81{\cdot}5,\quad \frac{\tau_{\prime}}{\tau}={\cdot}46035=\frac{1}{2{\cdot}17226}.$$

Mode of reading schedules explained.

To write down any term, take the universal coefficient, the general coefficient for the class of tides, the special coefficient, and multiply by the cosine of the argument. The result, taken with the positive sign, is a term in the equilibrium tide, with water covering the whole earth. The transition to the actual case by the introduction of a factor and a delay of phase (to be derived from observation) has been already explained. The sum of all the terms is the complete expression for the height of tide h.

Schedule of Lunar Tides.

[A, i.]—Universal Coefficient $=\frac{3}{2}\frac{m}{M}\left(\frac{a}{c}\right)^3 a$.

Semi-diurnal Tides; General Coefficient $=\cos^2\lambda$.

Descriptive Name.	Initial.	Coefficient.	Mean Value of Coefficient.	Argument $2t+2(h-\nu)$.	Speed in Degrees per m.s. Hour.
Principal lunar.	M2	$\frac{1}{2}(1-\frac{5}{2}e^2)\cos^4\frac{1}{2}I$	.45426	$-2(s-\xi)$	28.9841042

---

[1] Fused with $2\gamma-\sigma+\varpi$.

[2] m is the ratio of the moon's mean motion to the sun's.

[3] In these three entries the lower number gives the value when the coefficients of the evection and variation have their full values as derived from lunar theory.

[4] Indicated by 2MS as a compound tide (see below, § 24).

[5] A fusion of $\gamma-\sigma\pm\varpi$, of which the latter is the tide named.

[6] The upper number is the mean value of the coefficient of the tide $\gamma-\sigma-\varpi$; the lower applies to the tide M_1, compounded from the tides $\gamma-\sigma-\varpi$ and $\gamma-\sigma+\varpi$.

[7] The lower number gives the value when the coefficients in the evection have their full value as derived from lunar theory.

[B.]—*Schedule of Solar Tides.*

Solar tides; Universal Coefficient $=\frac{3}{2}\frac{M}{m}\left(\frac{a}{c}\right)^3 a$.

Descriptive Name.	Initial.	Coefficient.	Value of Coefficient.	Argument.	Speed in Degrees per m.s. Hour.
[i.] —Semi-diurnal Tides; General Coefficient $=\cos^2\lambda$.					
Principal solar.	S_2	$\frac{\tau_\prime}{\tau}(1-\frac{5}{2}e_\prime^2)\frac{1}{2}\cos^4\frac{1}{2}\omega$	.21137	$2t$	30.0000000°
Luni-solar (solar portion).	K_2	$\frac{\tau_\prime}{\tau}(1+\frac{3}{2}e_\prime^2)\frac{1}{4}\sin^2\omega$	.01823	$2t+2h$	30.0821372°
Larger elliptic.	T	$\frac{\tau_\prime}{\tau}\frac{1}{2}\frac{7}{2}e_\prime\cos^4\frac{1}{2}\omega$	.01243	$2t-(h-p_\prime)$	29.9589314°
[ii.]—Diurnal Tides; General Coefficient $=\sin 2\lambda$.					
Solar diurnal.	P	$\frac{\tau_\prime}{\tau}(1-\frac{3}{2}e_\prime^2)\frac{1}{2}\sin\omega\cos^2\frac{1}{2}\omega$	.08775	$t-h+\frac{1}{2}\pi$	14.9589314°
Luni-solar (solar portion).	K_1	$\frac{\tau_\prime}{\tau}(1-\frac{3}{2}e_\prime^2)\frac{1}{2}\sin\omega\cos\omega$	.08407	$t+h-\frac{1}{2}\pi$	15.0410686°
[iii.]—Long Period Tides; General Coefficient $\frac{1}{2}-\frac{3}{2}\sin^2\lambda$.					
Semi-annual.	Ssa	$\frac{\tau_\prime}{\tau}(1-\frac{3}{2}e_\prime^2)\frac{1}{2}\sin^2\omega$	·03643	$2h$	0.0821372°

Scale of importance of tides.

From the fourth columns we see that the coefficients in descending order of magnitude are M_2, K_1 (both combined), S_2, O, K_1 (lunar), N, P, K_1 (solar), K_2 (both combined), K_2 (lunar), Mf, Q, Mm, K_2 (solar), Ssa, ν, M_1, J, L, T, 2N, μ, OO, $3\sigma-\varpi$, $\gamma-3\sigma-\varpi+2\eta$, $\gamma-4\sigma+2\varpi$, $\sigma-2\eta+\varpi$, $2(\sigma-\eta)$, λ.

The tides depending on the fourth power of the moon's parallax arise from the potential $V=\frac{m}{r^4}\rho^3(\frac{5}{2}\cos^3 z-\frac{3}{2}\cos z)$. They give rise to a small diurnal tide M_1, and to a small ter-diurnal tide M_3; but we shall not give the analytical development.

§ 24. *Meteorological Tides, Over-Tides, and Compound Tides.*

Meteorological tides.

All tides whose period is an exact multiple or submultiple of a mean solar day, or of a tropical year, are affected by meteorological conditions. Thus all the tides of the principal solar astronomical series S, with speeds $\gamma-\eta$, $2(\gamma-\eta)$, $3(\gamma-\eta)$, etc., are subject to more or less meteorological perturbation. An annual inequality in the diurnal meteorological tide S_1 will also give rise to a tide $\gamma-2\eta$, and this will be fused with and indistinguishable from the astronomical P: it will also give rise to a tide with speed γ, which will be indistinguishable from the astronomical part of K_1. Similarly the astronomical tide K_2 may be perturbed by a semi-annual inequality in the semi-diurnal astronomical tide of speed $2(\gamma-\eta)$. Although the diurnal elliptic tide S_1 or $\gamma-\eta$ and the semi-annual and annual tides of speeds 2η and η are all probably quite insensible as arising from astronomical causes, yet they have been found of sufficient importance to be considered. The annual and semi-annual tides are of enormous importance in some rivers, representing in fact the yearly flooding in the rainy season. In the reduction of these tides the arguments of the S series are t, $2t$, $3t$, etc., and of the annual, semi-annual, ter-annual tides h, $2h$, $3h$. As far as can be foreseen, the magnitudes of these tides are constant from year to year.

Over-tides.

We have in § 21 considered the dynamical theory of over-tides. The only tides of this kind in which it has hitherto been thought necessary to represent the change of form in shallow water belong to the principal lunar and principal solar series. Thus, besides the fundamental astronomical tides M_2 and S_2, the over-tides M_4, M_6, M_8, and S_4, S_6 have been deduced by harmonic analysis. The height of the fundamental tide M_2 varies from year to year, according to the variation in the obliquity of the lunar orbit, and this variability is represented by the coefficient $\cos^4\frac{1}{2}I$. It is probable that the variability of M_4, M_6, M_8 will be represented by the square, cube, and fourth power of that coefficient, and theory (§ 21) indicates that we should make the argument of the over-tide a multiple of the argument of the fundamental, with a constant subtracted.

Compound tides.

Compound tides have been also considered dynamically in § 21. By combining the speeds of the important tides, it will be found that there is in many cases a compound tide which has itself a speed identical with that of an astronomical or meteorological tide. We thus find that the tides O, K_1, Mm, P, M_2, Mf, Q, M_1, L are liable to perturbation in shallow water. If either or both the component tides are of lunar origin, the height of the compound tide will change from year to year, and will probably vary proportionally to the product of the coefficients of the component tides. For the purpose of properly reducing the numerical value of the compound tides, we require not merely the speed, but also the argument. The following schedule gives the adopted initials, argument, and speed of the principal compound tides. The coefficients are the products of those of the two tides to be compounded.

[C.]—*Schedule of Compound Tides.*

Initials.	Arguments Combined.	Speed.	Speed in Degrees per m. s. Hour.
MK	M_2+K_1 M_4-O	$3\gamma-2\sigma$	44.0251728°
MS	M_2+S_2	$4\gamma-2\sigma-2\eta$	58.9841042°
MSf	S_2-M_2	$2\sigma-2\eta$	1.0158958°
2MK	M_2+O M_4-K_1	$3\gamma-4\sigma$	42.9271398°
...	S_2+K_1	$3\gamma-2\eta$	45.0410686°

...	S_2+O	$3\gamma-2\sigma-2\eta$	43.9430356°
...	S_2-O	$\gamma+2\sigma-2\eta$	16.0569644°
2SM	S_4-M_2	$2\gamma+2\sigma-4\eta$	31.0158958°
...	M_2+S_4	$6\gamma-2\sigma-4\eta$	88.9841042°
2MS	M_4-S_2	$2\gamma-4\sigma+2\eta$	27.9682084°
...	M_4+S_2	$6\gamma-4\sigma-2\eta$	87.9682084°

§ 25. *On the Form of Presentation of Results of Tidal Observations.*

Immediate result of harmonic analysis.

Supposing n to be the speed of any tide in degrees per mean solar hour, and t to be mean solar time elapsing since 0^h of the first day of (say) a year of continuous observation, then the immediate result of harmonic analysis is to obtain A and B, two heights (estimated in feet and tenths) such that the height of this tide at the time t is given by $A\cos nt+B\sin nt$. If we put $R=\sqrt{A^2+B^2}$, and $\tan\zeta=B/A$, then the tide is represented by

$$R\cos(nt-\zeta).$$

In this form R is the semi-range of the tide in British feet, and ζ is an angle such that ζ/n is the time elapsing after 0^h of the first day until it is high water of this particular tide. It is obvious that ζ may have any value from 0° to 360°, and that the results of the analysis of successive years of observation will not be comparable with one another when presented in this form.

Final form: tidal constants.

But let us suppose that the results of the analysis are presented in a number of terms of the form

$$fH\cos(V+u-\kappa),$$

where V is a linear function of the moon's and sun's mean longitudes, the mean longitude of the moon's and sun's perigees, and the local mean solar time at the place of observation, reduced to angle at 15° per hour. V increases uniformly with the time, and its rate of increase per mean solar hour is the n of the first method, and is called the speed of the tide. It is supposed that u stands for a certain function of the longitude of the node of the lunar orbit at an epoch half a year later than 0^h of the first day. Strictly speaking, u should be taken as the same function of the longitude of the moon's node, varying as the node moves; but, as the variation is but small in the course of a year, u may be treated as a constant and put equal to an average value for the year, which average value is taken as the true value of u at exactly mid year. Together $V+u$ constitute that function which has been tabulated as the "argument" in the schedules of § 23. Since $V+u$ are together the whole argument according to the equilibrium theory of tides, with sea covering the whole earth, it follows that κ/n is the lagging of the tide which arises from kinetic action, friction of the water, imperfect elasticity of the earth, and the distribution of land. It is supposed that H is the mean value in British feet of the semi-range of the particular tide in question; f is a numerical factor of augmentation or diminution, due to the variability of the obliquity of the lunar orbit. The value of f is the ratio of the "coefficient" in the third column of the preceding schedules to the mean value of the same term. For example, for all the solar tides f is unity, and for the principal lunar tide M_2 it is equal to $\cos^4\frac{1}{2}I \div \cos^4\frac{1}{2}\omega \cos^4\frac{1}{2}i$; for the mean value of this term has a coefficient $\cos^4\frac{1}{2}\omega \cos^4\frac{1}{2}i$. It is obvious, then, that, if the tidal observations are consistent from year to year, H and κ should come out the same from each year's reductions. It is only when the results are presented in such a form as this that it will be possible to judge whether the harmonic analysis is yielding satisfactory results. This mode of giving the tidal results is also essential for the use of a tide-predicting machine (see § 38).

---

[1] The mean value of this coefficient is $\frac{1}{3}(1+\frac{3}{2}e^2)(1-\frac{3}{2}\sin^2 i)(1-\frac{3}{2}\sin^2\omega)=.25$, and the variable part is approximately $-(1+\frac{3}{2}e^2)\sin i\cos i\sin\omega\cos\omega\cos N=-.0328\cos N$.

[2] The lower of these two numbers gives the value when the coefficients in the evection and variation have their full values as derived from lunar theory.

[3] Indicated by MSf as a compound tide.

We must now show how to determine H and κ from R and ζ. It is clear that $H = R/f$, and the determination of f from the schedules depends on the evaluation of the mean value of each of the terms in the schedules, into which we shall not enter. If V_0 be the value of V at 0^h of the first day, then clearly

$$-\zeta = V_0 + u - \kappa,$$

so that

$$\kappa = \zeta + V_0 + u.$$

Thus the rule for the determination of κ is: *Add to the value of ζ the value of the argument at 0^h of the first day.*

Tidal constants.

The results of harmonic analysis are usually tabulated by giving H, κ under the initial letter of each tide; the results are thus comparable from year to year.[1] For the purpose of using the tide-predicting machine the process of determining H and κ from R and ζ has simply to be reversed, with the difference that the instant of time to which to refer the argument is 0^h of the first day of the new year, and we must take note of the different value of u and f for the new year. Tables[2] have been computed for f and u for all longitudes of the moon's node and for each kind of tide, and the mean longitudes of moon, sun, and lunar perigee may be extracted from any ephemeris. Thus when the mean semi-range H and retardation κ of any tide are known its height may be computed for any instant. The sum of the heights for all the principal tides of course gives the actual height of water.

§ 26. *Numerical Harmonic Analysis for Tides of Short Period.*

Treatment of tide curves.

The tide-gauge (described below, § 36) furnishes us with a continuous graphical record of the height of the water above some known datum mark for every instant of time. The first operation performed on the tidal record is the measurement in feet and decimals of the height of water above the datum at every mean solar hour. The period chosen for analysis is about one year and the first measurement corresponds to noon.

If T be the period of any one of the diurnal tides, or the double period of any one of the semi-diurnal tides, it approximates more or less nearly to 24 m.s. hours, and, if we divide it into twenty-four equal parts, we may speak of each as a T-hour. We shall for brevity refer to mean solar time as S-time. Suppose, now, that we have two clocks, each marked with 360°, or 24 hours, and that the hand of the first, or S-clock, goes round once in 24 S-hours, and that of the second, or T-clock, goes round once in twenty-four T-hours, and suppose that the two clocks are started at 0° or 0^h at noon of the initial day. For the sake of distinctness, let us imagine that a T-hour is longer than an S-hour, so that the T-clock goes slower than the S-clock. The measurements of the tide curve give us the height of water exactly at each S-hour; and it is required from these data to determine the height of water at each T-hour. For this end we are, in fact, instructed to count T-time, but are only allowed to do so by reference to S-time, and, moreover, the time is always to be specified as an integral number of hours. Commencing with 0^h of the first day, we begin counting 0, 1, 2, etc., as the T-hand comes up to its hour-marks. But, as the S-hand gains on the T-hand, there will come a time when, the T-hand being exactly at the p hour-mark, the S-hand is nearly as far as $p+\frac{1}{2}$. When, however, the T-hand has advanced to the $p+1$ hour-mark, the S-hand will be a little beyond $p+1+\frac{1}{2}$,—that is to say, a little less than half an hour before $p+2$. Counting, then, in T-time by reference to S-time, we jump from p to $p+2$. The counting will go on continuously for a number of hours nearly equal to $2p$, and then another number will be dropped, and so on throughout the whole year. If it had been the T-hand which went faster than the S-hand, it is obvious that one number would be repeated at two successive hours instead of one being dropped. We may describe each such process as a "change."

Method of analysis.

Now, if we have a sheet marked for entry of heights of water according to T-hours from results measured at S-hours, we must enter the S-measurements continuously up to p, and we then come to a change; dropping one of the S-series, we go on again continuously until another change, when another is dropped; and so on. Since a change occurs at the time when a T-hour falls almost exactly half-way between two S-hours, it will be more accurate at a change to insert the two S-entries which fall on each side of the truth. If this be done the whole of the S-series of measurements is entered on the T-sheet. Similarly, if it be the T-hand which goes faster than the S-hand, we may leave a gap in the T-series instead of duplicating an entry. For the analysis of the T-tide there is therefore prepared a sheet arranged in rows and columns; each row corresponds to one T-day, and the columns are marked 0^h, 1^h, . . . 23^h; the 0's may be called T-noons. A dot is put in each space for entry, and where there is a change two dots are put if there is to be a double entry, and a bar if there is to be no entry.[3] The numbers entered in each column are summed; the results are then divided, each by the proper division for its column, and thus the mean value for that column is obtained. In this way 24 numbers are found which give the mean height of water at each of the 24 special hours. It is obvious that if this process were continued over a very long time we should in the end extract the tide under analysis from amongst all the others; but, as the process only extends over about a year, the elimination of the others is not quite complete. The elimination of the effects of the other tides may be improved by choosing the period for analysis not exactly equal to one year.

Necessity for augmenting factors.

Let us now return to our general notation, and consider the 24 mean values, each pertaining to the 24 T-hours. We suppose that all the tides except the T-tide are adequately eliminated, and, in fact, a computation of the necessary corrections for the absence of complete elimination, which is given in the *Tidal Report* to the British Association in 1872, shows that this is the case. It is obvious that any one of the 24 values does not give the true height of the T-tide at that T-hour, but gives the average height of the water, as due to the T-tide, estimated over half a T-hour before and half a T-hour after that hour. A consideration of this point shows that certain augmenting factors, differing slightly from unity, must be applied. In the reduction of the S-series of tides, the numbers treated are the actual heights of the water exactly at the S-hours, and therefore no augmenting factor is requisite.

We must now explain how the harmonic analysis, which the use of these factors presupposes, is carried out.

If t denotes T-time expressed in T-hours, and n is 15°, we express the height h, as given by the averaging process above explained, by the formula

$$h = A_0 + A_1 \cos nt + B_1 \sin nt + A_2 \cos 2nt + B_2 \sin 2nt + \ldots,$$

where t is 0, 1, 2, . . . 23. Then, if Σ denotes summation of the series of 24 terms found by attributing to t its 24 values, it is obvious that

$$A_0 = \tfrac{1}{24}\Sigma h;\ A_1 = \tfrac{1}{12}\Sigma h \cos nt;\ B_1 = \tfrac{1}{12}\Sigma h \sin nt;$$
$$A_2 = \tfrac{1}{12}\Sigma h \cos 2nt;\ B_2 = \tfrac{1}{12}\Sigma h \sin 2nt;\ \text{etc., etc.}$$

Analysis.

Since n is 15° and t is an integer, it follows that all the cosines and sines involved in these series are equal to one of the following, viz., 0, $\pm\sin 15°$, $\pm\sin 30°$, $\pm\sin 45°$, $\pm\sin 60°$, $\pm\sin 75°$, ± 1. It is found convenient to denote these sines by 0, $\pm S_1$, $\pm S_2$, $\pm S_3$, $\pm S_4$, $\pm S_5$, ± 1. The multiplication of the 24 h's by the various S's and the subsequent additions may be arranged in a very neat tabular form, like that given in the *Report* to the British Association in 1883. The A's and B's having been thus deduced, we have $R = \sqrt{(A^2 + B^2)}$. R must then be multiplied by the augmenting factor. We thus have the augmented R. Next the angle whose tangent is B/A gives ζ. The addition to ζ of the appropriate V_0+u gives κ, and the multiplication of R by the appropriate 1/f gives H. The reduction is then complete. An actual numerical example of harmonic analysis is given in the *Admiralty Scientific Manual* (1886) in the article "Tides"; but the process there employed is slightly different from the above, because the series of observations is supposed to be a short one.

§ 27. *Harmonic Analysis for Tides of Long Period.*

Tides of long period.

For the purpose of determining the tides of long period we have to eliminate the oscillations of water-level arising from the tides of short period. As the quickest of these tides has a period of many days, the height of mean water at one instant for each day gives sufficient data. Thus there will in a year's observations be 365 heights to be submitted to harmonic analysis. To find the daily mean for any day we take the arithmetic mean of 24 consecutive hourly values, beginning with the height at noon. This height will then apply to the middle instant of the period from 0^h to 23^h,—that is to say, to 11^h 30^m at night. The formation of a daily mean does not obliterate the tidal oscillations of short period, because none of the tides, except those of the principal solar series, have commensurable periods in mean solar time. A small correction, or "clearance of the daily mean," has therefore to be applied for all the important tides of short period, except for the solar tides. Passing by this clearance, we next take the 365 daily means, and find their mean value. This gives the mean height of water for the year. We next subtract the mean height from each of the 365 values, and find 365 quantities δh, giving the daily height of water above the mean height. These quantities are to be the subject of the harmonic analysis, and the tides chosen for evaluation are those which have been denoted above as Mm, Mf, MSf, Sa, Ssa.

$$\text{Let } \delta h = \left.\begin{aligned} &\mathrm{A}\cos(\sigma-\varpi)t + \mathrm{B}\sin(\sigma-\varpi)t\\ +&\mathrm{C}\cos 2\sigma t \quad + \mathrm{D}\sin 2\sigma t\\ +&\mathrm{C}'\cos 2(\sigma-\eta)t + \mathrm{D}'\sin 2(\sigma-\eta)t\\ +&\mathrm{E}\cos \eta t \quad + \mathrm{F}\sin \eta t\\ +&\mathrm{G}\cos 2\eta t \quad + \mathrm{H}\sin 2\eta t \end{aligned}\right\}\ldots\ldots\ldots(73),$$

Harmonically analyzed.

where t is time measured from the first 11^h 30^m. If we multiply the 365 δh's by 365 values of $\cos(\sigma-\varpi)t$ and effect the summation, the coefficients of B, C, D, etc., are very small, and that of A is nearly 182½. Similarly, multiplying by $\sin(\sigma-\varpi)t$, $\cos 2\sigma t$, etc., we obtain 10 equations for A, B, C, etc., in each of which one coefficient is nearly 182½ and the rest small. These equations are easily solved by successive approximation. In this way A, B, C, etc., are found, and afterwards the clearance to which we have alluded is applied. Finally the cleared A, B, C, etc., are treated exactly as were the components of the tides of short period. Special forms and tables have been prepared for facilitating these operations.

V. SYNTHETIC METHOD.

§ 28. *On the Method and Notation.*

Synthetic method.

The general nature of the synthetic method has been already explained; we now propose to develop the expressions for the tide from the result as expressed in the harmonic notation. If it should be desired to make a comparison of the results of tidal observation as expressed in the synthetic method with those of the harmonic method, or the converse, or to compute a tide-table from the harmonic constants by reference to the moon's transits and from the declinations and parallaxes of sun and moon, the analyical expressions of the following sections are necessary.

In chapter iv. the mean semi-range and angle of retardation or lag of any one of the tides have been denoted by H and κ. We shall here, however, require to introduce several of the H's and κ's into the same expression, and they must therefore be distinguished from one another. This may in general be conveniently done by writing as a subscript letter the initial of the corresponding tide; for example H_m, κ_m will be taken to denote the H and κ of the principal lunar tide M_2. This notation does not suit the K_2 and K_1 tides, and we shall therefore write H'', κ'' for the semi-diurnal K_2, and H', κ' for the diurnal K_1 tide. These two tides proceed according to sidereal time and arise from the sun and moon jointly, and a synthesis of the two parts of each is effected in the harmonic method, although that synthesis is not explained in chapter iv. The ratio of the solar to the lunar part of the total K_2 tide is .46407; hence .683 H″ is the lunar portion of the total K_2. There will be no occasion to separate the two portions of K_1, and we shall retain the synthesis which is effected in the harmonic method.

§ 29. *Semi-Diurnal Tides.*

Mean longitude and elements replaced by hour-angle, declination, and parallax.

The process adopted is to replace the mean longitudes and elements of the orbit in each term of the harmonic development of the schedules of § 23 by hour-angles, declinations, and parallaxes.

At the time t (mean solar time of port reduced to angle) let α, δ, ψ be ☽'s R.A., declination, and hour-angle, and l ☽'s longitude measured from the "intersection." These and other symbols when written with subscript accent are to apply to the sun. Then ν being the R.A. of the intersection, we have from the right-angled spherical triangle of which the sides are l, δ, $\alpha-\nu$ the relations

$$\tan(\alpha-\nu)=\cos I\tan l,\ \sin\delta=\sin I\sin l\ldots\ldots\ldots(74).$$

Now $s-\xi$ is the ☽'s mean longitude measured from the intersection and $s-p$ is the mean anomaly; hence approximately

$$l=s-\xi+2e\sin(s-p)\ldots\ldots\ldots\ldots\ldots\ldots(75).$$

From (74) and (75) we have approximately

$$\alpha=s+(\nu-\xi)+2e\sin(s-p)-\tan^2\tfrac{1}{2}I\sin 2(s-\xi).$$

Now, h being the ⊙'s mean longitude, $t+h$ is the sidereal hour-angle and $\psi=t+h-\alpha$.

Hence

$$t+h-s-(\nu-\xi)=\psi+2e\sin(s-p)$$
$$-\tan^2\tfrac{1}{2}I\sin 2(s-\xi)\ldots\ldots\ldots\ldots\ldots\ldots\ldots(76).$$

Again, if we put

$$\cos^2\Delta=1-\tfrac{1}{2}\sin^2 I\ldots\ldots\ldots\ldots\ldots\ldots\ldots(77),$$

we have approximately from (74) and (75)

$$\left.\begin{aligned} &\frac{\cos^2\delta-\cos^2\triangle}{\sin^2\triangle}=\cos 2(s-\xi)\\ \text{whence}\quad &\frac{\sin\delta\cos\delta}{\sigma\sin^2\triangle}\frac{d\delta}{dt}=\sin 2(s-\xi) \end{aligned}\right\}\ldots\ldots\ldots\ldots(78),$$

Obviously Δ is such a declination that $\sin^2\Delta$ is the mean value of $\sin^2\delta$ during a lunar month. Again, if P be the ratio of the ☽'s parallax to her mean parallax, the equation to the ellipse described

$$\left.\begin{aligned} \text{gives}\quad &\frac{1}{e}(P-1)=\cos(s-p)\\ \text{whence}\quad &-\frac{1}{e(\sigma-\varpi)}\frac{dP}{dt}=\sin(s-p) \end{aligned}\right\}\ldots\ldots\ldots\ldots\ldots(79).$$

Now it appears in schedule A of § 23 that the arguments of all the lunar semi-diurnal tides are of the form $2(t+h-\nu)\pm 2(s-\xi)$ or $\pm(s-p)$. It is clear, therefore, that the cosines of such angles may by the relations (76), (78), (79) be expressed in terms of hour-angles, declinations, and parallaxes. Also by means of (77) we may introduce Δ in place of I in the coefficients of each term. An approximate formula for Δ is $16.51°+3.44°\cos N-0.19°\cos 2N$. In the *Report to the British Association* for 1885, the details of the processes indicated are given.

Age of declinational and parallactic corrections.

Before giving the formula it must be remarked that the result is expressed more succinctly by the introduction of the symbol δ' to denote the ☽'s declination at a time earlier than that of observation by an interval which may be called the "age of the declinational inequality," and is computed from the formula $\tan(\kappa''-\kappa_m)/2\sigma$ or $52.2^h\tan(\kappa''-\kappa_m)$. Similarly, it is convenient to introduce P' to denote the value of P at a time earlier than that of observation by the "age of the parallactic inequality," to be computed from $\tan(\kappa_m-\kappa_n)/(\sigma-\varpi)$ or $105.3^h\tan(\kappa_m-\kappa_n)$. These two "ages" probably do not differ in general much from a third period, computed from $(\kappa_s-\kappa_m)/2(\sigma-\eta)$, which is called the "age of the tides."

The similar series of transformations when applied to the solar tides leads to simpler results, because $\Delta_{,}$ is a constant, being 16.33°, and the "ages" may be treated as zero; besides the terms depending on $d\delta_{,}/dt$ and $dP_{,}/dt$ are negligible. If now we denote by h_2 the height of water with reference to mean water-mark, in so far as the height is affected by the harmonic tides M_2, S_2, K_2, N, L, T, R,[1] the harmonic expression is transformed into

Total semi-diurnal tide.

$$\mathrm{h}_2=\frac{\cos^2\triangle}{\cos^2\triangle_{,}}\mathrm{H}_m\cos(2\psi-\kappa_m)+\mathrm{H}_s\cos(2\psi_{,}-\kappa_s)$$
$$+\frac{\cos^2\delta'-\cos^2\triangle}{\sin^2\triangle_{,}}.683\,\mathrm{H}''\cos(2\psi-\kappa'')$$
$$+\frac{\cos^2\delta_{,}-\cos^2\triangle_{,}}{\sin^2\triangle_{,}}.317\,\mathrm{H}''\cos(2\psi_{,}-\kappa'')$$

---

[1] R is the smaller solar elliptic tide bearing the same relation to T that L does to N amongst the lunar tides. It was omitted as unimportant in schedule B, i.] of § 23.

$$-\frac{\sin\delta\cos\delta}{\sigma\sin^2\Delta_{,}}\frac{d\delta}{dt}\left[\frac{.683\,\mathrm{H}''}{\cos(\kappa''-\kappa_m)}-\mathrm{H}_m\tan^2\Delta_{,}\right]\sin(2\psi-\kappa_m)$$
$$+\frac{\cos^2\Delta}{\cos^2\Delta_{,}}(P'-1)\frac{\mathrm{H}_n\cos\kappa_n-\mathrm{H}_l\cos\kappa_l}{e\cos\varepsilon}\cos(2\psi-\varepsilon)$$
$$+(P_{,}-1)\frac{\mathrm{H}_t-\mathrm{H}_r}{e_{,}}\cos(2\psi_{,}-\kappa_s)$$
$$+\frac{\cos^2\Delta}{e\cos^2\Delta_{,}}\frac{dP/dt}{(\sigma-\varpi)}\left[4\mathrm{H}_m e-\frac{\mathrm{H}_n}{\cos(\kappa_m-\kappa_n)}-\frac{\mathrm{H}_l}{\cos(\kappa_l-\kappa_m)}\right]$$
$$\sin(2\psi-\kappa_m)\ \ldots\ldots\ldots\ldots(80),$$

where ε is an auxiliary angle defined by

$$\tan\varepsilon=\frac{\mathrm{H}_n\sin\kappa_n-\mathrm{H}_l\sin\kappa_l}{\mathrm{H}_n\cos\kappa_n-\mathrm{H}_l\cos\kappa_l}\ \ldots\ldots(81).$$

The first two terms are the principal tides, and the physical origin of the remaining small terms is indicated by their involving δ', $\delta_{,}$, $d\delta/dt$, P, $P_{,}$, dP/dt. The terms in $d\delta/dt$ and dP/dt are generally smaller than the others.

The approximation may easily be carried further. But the above is in some respects a closer approximation than the expression from which it is derived, since the hour-angles, declinations, and parallaxes necessarily involve all the lunar and solar inequalities.

§ 30. *Syntheses of Solar and of Lunar Portions of the Semi-Diurnal Tide.*

Commencement of synthesis.

Let us write

$$\mathrm{M}=\frac{\cos^2\Delta}{\cos^2\Delta_{,}}\mathrm{H}_m+\frac{\cos^2\delta'-\cos^2\Delta}{\sin^2\Delta_{,}}.683\,\mathrm{H}''\cos(\kappa''-\kappa_m)$$
$$+\frac{\cos^2\Delta}{\cos^2\Delta_{,}}(P'-1)\frac{\mathrm{H}_n\cos\kappa_n-\mathrm{H}_l\cos\kappa_l}{e\cos\varepsilon}\cos(\varepsilon-\kappa_m);$$
$$2\mu=\kappa_m+\frac{\cos^2\delta'-\cos^2\Delta}{\sin^2\Delta_{,}}.683\,\mathrm{H}''\sin(\kappa''-\kappa_m)$$
$$+\frac{\cos^2\Delta}{\cos^2\Delta_{,}}(P'-1)\frac{\mathrm{H}_n\cos\kappa_n-\mathrm{H}_l\cos\kappa_l}{e\cos\varepsilon}\sin(\varepsilon-\kappa_m)$$
$$-\frac{\sin\delta\cos\delta}{\sigma\sin^2\Delta_{,}}\frac{d\delta}{dt}\left[\frac{.683\,\mathrm{H}''}{\cos(\kappa''-\kappa_m)}-\mathrm{H}_n\tan^2\Delta_{,}\right]$$
$$+\frac{\cos^2\Delta}{e\cos^2\Delta_{,}}\frac{dP/dt}{\sigma-\varpi}\left[4\mathrm{H}_m e-\frac{\mathrm{H}_n}{\cos(\kappa_m-\kappa_n)}-\frac{\mathrm{H}_l}{\cos(\kappa_l-\kappa_m)}\right];$$
$$\mathrm{M}_{,}=\mathrm{H}_s+\frac{\cos^2\delta_{,}-\cos^2\Delta_{,}}{\sin^2\Delta_{,}}.317\,\mathrm{H}''+(P_{,}-1)\frac{\mathrm{H}_t-\mathrm{H}_r}{e_{,}};$$
$$2\mu_{,}=\kappa_s\ \ldots\ldots\ldots\ldots\ldots\ldots(82).$$

Since observation and theory agree in showing that κ'' is generally very nearly equal to κ_s, we are justified in substituting κ_s for κ'' in the small solar declinational term of (80) involving .317 H″. Then, using (82) in (80),

$$\mathrm{h}_2=\mathrm{M}\cos2(\psi-\mu)+\mathrm{M}_{,}\cos2(\psi_{,}-\mu_{,})\ldots\ldots(83).$$

One solar and one lunar term.

If the equilibrium theory of tides were true, each H would be proportional to the corresponding term in the harmonically developed potential. This proportionality holds nearly between tides of almost the same speed; hence, using the expressions in the column of coefficients in schedule [B, i.], § 23 (with the additional tide R there omitted, but having a coefficient $(\tau_{,}/\tau)\tfrac{1}{2}.\tfrac{1}{2}e_{,}\cos^4\tfrac{1}{2}\omega$, found by symmetry with the lunar tide L), and introducing $\Delta_{,}$ in place of ω in the solar tides, we may assume the truth of the proportion

$$\frac{\cos^2\Delta_{,}}{\sin^2\Delta_{,}}.317\,\mathrm{H}''=\tfrac{1}{3}\frac{\mathrm{H}_t-\mathrm{H}_r}{e_{,}}=\mathrm{H}_s.$$

With this assumption, M, reduces to

$$\mathrm{M}_{,}=\frac{\cos^2\delta_{,}}{\cos^2\Delta_{,}}\mathrm{H}_s+3(P_{,}-1)\mathrm{H}_s=\frac{\cos^2\delta_{,}}{\cos^2\Delta_{,}}\mathrm{H}_s[1+3(P_{,}-1)].$$

$$\text{Hence }\mathrm{M}_{,}=P_{,}^3\frac{\cos^2\delta_{,}}{\cos^2\Delta_{,}}\mathrm{H}_s\ \ldots\ldots\ldots\ldots(84).$$

This is the law which we should have derived directly from the equilibrium theory, with the hypothesis that all solar semi-diurnal tides suffer nearly equal retardation. Save for meteorological influences, this must certainly be true.

A similar synthesis of M cannot be carried out, because the considerable diversity of speed amongst the lunar tides makes a similar appeal to the equilibrium theory incorrect. It may be seen, however, that it would be more correct to write $\cos^2\delta'$ instead of $\cos^2\Delta$ in the coefficient of the parallactic terms in M and 2μ.

The three terms of M in (82) give the height of lunar tide with its declinational and parallactic corrections, and similarly the formula for μ in (82) gives its value and corrections.

If now τ denotes the mean solar time elapsing since the moon's upper transit and γ the angular velocity of the earth's rotation, it is clear that the moon's hour-angle

$$\psi=(\gamma-d\alpha/dt)\tau;$$

and, since $\mathrm{M}\cos2(\psi-\mu)$ is a maximum when $\psi=\mu$ or differs from μ by 180°, it follows that $\mu/(\gamma-d\alpha/dt)$ is the "interval" from the moon's upper or lower transit to high water of the lunar tide. Since τ is necessarily less than 12^h, we may during the interval from transit to high water take as an approximation $d\alpha/dt=\sigma$, the moon's mean motion.[1] Hence that interval is $\mu/(\gamma-\sigma)$, or $\tfrac{2}{29}\mu$ hours nearly, when μ is expressed in degrees. Thus (82) for μ gives by its first term the mean interval for the lunar tide, and by the subsequent terms the declination and parallactic corrections.

Approximate formula.

We have said that the synthesis of M cannot be carried out as in the case of $\mathrm{M}_{,}$, but the partial synthesis below will give fairly good results. The proposed formula is

$$\mathrm{M}=P_{,}^3\frac{\cos^2\Delta}{\cos^2\Delta_{,}}\mathrm{H}_m+\frac{\cos^2\delta'-\cos^2\Delta}{\sin^2\Delta_{,}}.683\,\mathrm{H}''\cos(\kappa''-\kappa_m);$$
$$2\mu=\kappa_m+\frac{\cos^2\delta'-\cos^2\Delta}{\sin^2\Delta_{,}}.683\,\mathrm{H}''\sin(\kappa''-\kappa_m);$$
$$\mathrm{M}_{,}=P_{,}^3\frac{\cos^2\delta_{,}}{\cos^2\Delta_{,}}\mathrm{H}_s;$$
$$2\mu_{,}=\kappa_s\ \ldots\ldots\ldots\ldots\ldots\ldots(85).$$

These formulæ have been used in the example of the computation of a tide-table given in the *Admiralty Scientific Manual* (1886).

§ 31. *Synthesis of Lunar and Solar Semi-Diurnal Tides.*

Let A be the excess of ☽'s over ☉'s R. A., so that

$$\left.\begin{aligned}&\mathrm{A}=\alpha-\alpha_{,,}\\&\psi_{,}=\psi+\mathrm{A},\\\text{and}\quad&\mathrm{h}_2=\mathrm{M}\cos2(\psi-\mu)+\mathrm{M}_{,}\cos2(\psi+\mathrm{A}-\mu_{,})\end{aligned}\right\}\ldots(86).$$

The synthesis is then completed by writing

$$\mathrm{H}\cos2(\mu-\phi)=\mathrm{M}+\mathrm{M}_{,}\cos2(\mathrm{A}-\mu_{,}+\mu),$$
$$\mathrm{H}\sin2(\mu-\phi)=\mathrm{M}_{,}\sin2(\mathrm{A}-\mu_{,}+\mu),$$

so that

$$\mathrm{h}_2=\mathrm{H}\cos2(\psi-\phi)\ \ldots\ldots\ldots\ldots(87).$$

Synthesis to obtain single term.

Then H is the height of the total semi-diurnal tide and $\phi/(\gamma-d\alpha/dt)$ or $\phi/(\gamma-\sigma)$ or $\tfrac{2}{29}\phi$, when ϕ is given in degrees, is the "interval" from the moon's transit to high water.

The formulæ for H and ϕ may be written

$$\left.\begin{aligned}\mathrm{H}&=\sqrt{\{\mathrm{M}^2+\mathrm{M}_{,}^2+2\mathrm{M}\mathrm{M}_{,}\cos2(\mathrm{A}-\mu_{,}+\mu)\}}\\\tan2(\mu-\phi)&=\frac{\mathrm{M}_{,}\sin2(\mathrm{A}-\mu_{,}+\mu)}{\mathrm{M}+\mathrm{M}_{,}\cos2(\mathrm{A}-\mu_{,}+\mu)}\end{aligned}\right\}(88).$$

Fortnightly inequality.

They may be reduced to a form adapted for logarithmic calculation. Since A goes through its period in a lunation, it follows that H and ϕ have inequalities with a period of half a lunation. These are called the "fortnightly or semi-menstrual inequalities" in the height and interval.

Age of tide.

Spring tide obviously occurs when $\mathrm{A}=\mu_{,}-\mu$. Since the mean value of A is $s-h$ (the difference of the mean longitudes), and since the mean values of μ and $\mu_{,}$ are $\tfrac{1}{2}\kappa_m$, $\tfrac{1}{2}\kappa_s$, it follows that the mean value of the period elapsing after full moon and change of moon up to spring tide is $(\kappa_s-\kappa_m)/2(\sigma-\eta)$. The association of spring tide with full and change is obvious, and a fiction has been adopted by which it is held that spring tide is generated in those configurations of the moon and sun, but takes some time to reach the port of observation. Accordingly $(\kappa_s-\kappa_m)/2(\sigma-\eta)$ has been called the "age of the tide." The average age is about 36 hours as far as observations have yet been made. The age of the tide appears not in general to differ very much from the ages of the declinational and parallactic inequalities.

In computing a tide-table it is found practically convenient not to use A, which is the difference of R.A.'s at the unknown time of high water, but to refer the tide to A_0, the difference of R.A.'s at the time of the moon's transit. It is clear that A_0 is the apparent time of the moon's transit reduced to angle at 15° per hour. We have already remarked that $\phi/(\gamma-d\alpha/dt)$ is the interval from transit to high water, and hence at high water

$$\mathrm{A}=\mathrm{A}_0+\frac{d\alpha/dt-d\alpha_{,}/dt}{\gamma-d\alpha/dt}\phi\ \ldots\ldots\ldots(89).$$

---

[1] The tide has been referred by Lubbock and others to an earlier transit, and not to the one immediately preceding the time under consideration. In this case we cannot admit with great accuracy that $d\alpha/dt=\sigma$, since the interval may be 30 or 40 hours.

As an approximation we may attribute to all the quantities in the second term their mean values, and we then have

$$A = A_0 + \frac{\sigma - \eta}{\gamma - \sigma}\mu$$

and $$A - \mu_{,} + \mu = A_0 - \mu_{,} + \frac{\gamma - \eta}{\gamma - \sigma}\mu = A_0 - \mu_{,} + \tfrac{30}{29}\mu \quad (90).$$

This approximate formula (90) may be used in computing from (88) the fortnightly inequality in the "height" and "interval."

Reference to moon's transit.

In this investigation we have supposed that the declinational and parallactic corrections are applied to the lunar and solar tides before their synthesis; but it is obvious that the process might be reversed, and that we may form a table of the fortnightly inequality based on mean values H_m and H_s, and afterwards apply corrections. This is the process usually adopted, but it is less exact. The labor of computing the fortnightly inequality, especially by graphical methods, is not great, and the plan here suggested seems preferable.

§ 32. *Diurnal Tides.*

Diurnal tides not easily treated synthetically.

These tides have not been usually treated with completeness in the synthetic method. In the tide-tables of the British Admiralty we find that the tides at some ports are "affected by diurnal inequality;" such a statement may be interpreted as meaning that the tides are not to be predicted by the information given in the so-called tide-table. The diurnal tides are indeed complex, and do not lend themselves easily to a complete synthesis. In the harmonic notation the three important tides are K_1, O, P, and the lunar portion of K_1 is nearly equal to O in height, whilst the solar portion is nearly equal to P. A complete synthesis may be carried out on the lines adopted in treating the semi-diurnal tides, but the advantage of the plan is lost in consequence of large oscillations of the amplitude through the value zero, so that the tide is often represented by a negative quantity multiplied by a circular function. It is best, then, only to attempt a partial synthesis, and to admit the existence of two diurnal tides.

We see from schedules [A, ii.] and [B, i.], § 23, that the principal diurnal tides are those lettered O, P, K_1. Of these K_1 occurs both for the moon and the sun. The synthesis of the two parts of K_1 is affected without difficulty, and the result is a formula for the total K_1 tide like that in [A, ii.], but with the ν which occurs in the argument replaced by a different angle denoted as ν'. If then, we write

$$\left.\begin{aligned} V_0 &= t + h - 2s - \nu + 2\xi + \tfrac{1}{2}\pi \\ V' &= t + h - \nu' - \tfrac{1}{2}\pi \end{aligned}\right\} \ldots\ldots\ldots(91),$$

the three tides O, K_1, P are written as follows:—

$$\begin{aligned} O &= f_0 H_0 \cos(V_0 - \kappa_0), \\ K_1 &= f' H' \cos(V' - \kappa'), \\ P &= -H_p \cos[V' - \kappa' - (2h - \nu') + \kappa' - \kappa_p] \ldots\ldots\ldots(92). \end{aligned}$$

The last two tides have very nearly the same speed, so that we may assume $\kappa' = \kappa_p$, and that H_p has the same ratio to H' as in the equilibrium theory. Now, in schedules [A, ii.], [B, ii.], § 23, the coefficient of K_1, viz., H' (the sum of the lunar and solar parts), is .26522, and the coefficient of P, viz., H_p, is .08775. so that $H' = 3.023\ H_p$, or say $= 3H_p$. Hence we have

$$\begin{aligned} K_1 + P = H'\,[f' - \tfrac{1}{3}\cos(2h - \nu')]\cos(V' - \kappa') \\ - H'\,\tfrac{1}{3}\sin(2h - \nu')\sin(V' - \kappa'). \end{aligned}$$

If, therefore, we put

Partial synthesis.

$$\left.\begin{aligned} R'\cos\psi &= H'\,[f' - \tfrac{1}{3}\cos(2h - \nu')] \\ R'\sin\psi &= \tfrac{1}{3} H'\sin(2h - \nu') \end{aligned}\right\} \ldots\ldots(93),$$
$$K_1 + P = R'\cos(V' + \psi - \kappa').$$

It is clear that ψ and R' have a semi-annual inequality, and therefore for several weeks together R' and ψ may be treated as constant.

Now suppose that we compute V_0 and V' at the epoch—that is, at the initial noon of the period during which we wish to predict the tides—and with these values put

$$\zeta_0 = \kappa_0 - V_0 \text{ at epoch}, \quad \zeta' = \kappa' - V' \text{ at epoch} - \psi.$$

Then the speed of V_0 is $\gamma - 2\sigma$, or 13.94303° per hour, or 360° — 25.3673° per day; and the speed of V' is γ, or 15.0410686° per hour, or 360.9856° per day. Hence if t be the mean solar time on the $(n+1)$th day since the initial moment or epoch,

$$\begin{aligned} V_0 - \kappa_0 &= 360°n + 13.943°\,t - \zeta_0 - 25.367°n, \\ V' + \psi - \kappa' &= 360°n + 15.041°\,t - \zeta' + 0.986°n. \end{aligned}$$

Therefore the diurnal tides at time t of the $(n+1)$th day are given by

$$\left.\begin{aligned} O &= f_0 H_0 \cos[13.943°\,t - \zeta_0 - 25.367°n] \\ K_1 + P &= R'\cos[15.041°\,t - \zeta' + 0.986°n] \end{aligned}\right\} \ldots(94).$$

Diurnal corrections to height of H. W. and L.W.

If we substitute for t the time of high or low water as computed simply from the semi-diurnal tide, it is clear that the sum of these two expressions will give the diurnal correction for height of tide at high or low water, provided the diurnal tides are not very large. If we consider the maximum of a function

$$A\cos 2(t - \alpha) + B\cos n(t - \beta),$$

where B is small compared with A and n is nearly unity, we see that the time of maximum is given approximately by $t = \alpha$, with a correction δt determined from

$$-2A\sin(2\delta t) - nB\sin n(\alpha - \beta) = 0;$$

or $$\delta t = -\frac{180°}{\pi}\cdot\frac{nB}{4A}\sin n(\alpha - \beta).$$

In this way we find that the corrections to the time of high water from O and $K_1 + P$ are

$$\left.\begin{aligned} \delta t_0 &= -0.988^h\left(1 - \frac{\sigma}{\gamma - \sigma}\right)\frac{f_0 H_0}{H}\sin[13.943°t - \zeta_0 \\ &\qquad - 25.367°n] \\ \delta t' &= -0.988^h\left(1 + \frac{\sigma}{\gamma - \sigma}\right)\frac{R'}{H}\sin[15.041°t - \zeta' \\ &\qquad + 0.986°n] \end{aligned}\right\} (95).$$

H denoting the height and t the time of high water as computed from the semi-diurnal tide. If t next denotes the time of low water the same corrections with opposite sign give the corrections for low water.

Diurnal correction to time of H. W. and L. W.

If the diurnal tides are large a second approximation will be necessary. These formulæ have been used in computing a tide-table in the example given in the *Admiralty Scientific Manual* (1886).

§ 33. *Explanation of Tidal Terms in common use; Datum Levels.*

Tidal terms explained.

The mean height at spring tide between high and low water is called the *spring rise*, and is equal to $2(H_m + H_s)$. The height between mean high-water mark of neap tide and mean low-water mark at spring tide is called the *neap rise*, and is equal to $2H_m$. The mean height at neap tide between high and low water is called the *neap range*; this is equal to $2(H_m - H_s)$. Neap range is usually about one-third of spring range. The mean period between full or change of moon and spring tide is called the *age of the tide*; this is equal to $(\kappa_s - \kappa_m)/2(\sigma - \eta)$, or, if $\kappa_s - \kappa_m$ be expressed in degrees, $0.984^h \times (\kappa_s - \kappa_m)$; $\kappa_s - \kappa_m$ is commonly about 36°, and the age about 36^h. The period elapsing from the moon's upper or lower transit until it is high water is called the *interval* or the *lunitidal interval.* The interval at full moon or change of moon is called the *establishment of the port* or the *vulgar establishment.* The interval at spring tide is called the *corrected* or *mean establishment.*

The mean establishment may be found from the vulgar establishment by means of the spring and neap rise and the age of the tide, as follows.

Let α be the age of the tide reduced to angle at the rate of 1.016° to the hour. Then the mean establishment in hours is equal to the vulgar establishment in hours, diminished by a period expressed in hours numerically equal to $\frac{1}{29}$ of the angle whose tangent is $H_s \sin\alpha/(H_m + H_s\cos\alpha)$, expressed in degrees. Also H_s/H_m is equal to the ratio of the excess of spring rise over neap rise to neap rise.

The French have called a quantity which appears to be identical with $H_m + H_s$, or half the spring rise, the unit of height, and then define the height of any other tide by a tidal coefficient.[1]

Admiralty datum.

The practice of the British Admiralty is to refer their soundings and tide-tables to "mean low-water mark of ordinary spring tides." This datum is found by taking the mean of the low-water marks of such observations at spring tide as are available, or, if the observations are very extensive, by excluding from the mean such spring tides as appear to be abnormal, owing to the largeness of the moon's parallax at the time or any other cause. The Admiralty datum is not, then, susceptible of exact scientific definition; but, when it has once been fixed with reference to a bench mark ashore, it is expedient to adhere to it, by whatever process it was first fixed.

Indian datum.

It is now proposed to adopt for any new Indian tidal stations a low-water datum for the tide-table to be called "Indian low-water mark,"[2] and to be defined as $H_m + H_s + H' + H_0$ below mean-water level. Although such a datum is not chosen from any precise scientific considerations, it is susceptible of exact definition, is low enough to exclude almost all negative entries from the table (a *sine qua non* for a good datum), and will differ but little from the Admiralty datum, however that may be determined. A valuable list of datum levels is given by Mr. J. Shoolbred in a *Report* to the British Association in 1879.

§ 34. *On the Reduction of Observations of High and Low Water.*[1]

Observations of H.W. and L.W.

A continuous register of the tide or observation at fixed intervals of time, such as each hour, is certainly the best; but for the adequate use of such a record some plan analogous to harmonic analysis is necessary. Observations of high and low water only have, at least until recently, been more usual. Some care has to be taken with respect to these observations, for about high and low water an irregularity in the rise and fall becomes very noticeable, especially if the place of observation is badly chosen.[2] Observations should therefore be taken every five or ten minutes for half an hour or an hour, embracing the time of high and low water. The time and height of high and low water should then be found by plotting down a curve of heights, and by taking as the true tide-curve a line which presents a sweeping curvature and smooths away the minor irregularities. A similar but less elaborate process would render hourly observations more perfect. In the reduction the immediate object is to connect the times and heights of high and low water with the moon's transits by means of the establishment, age, and fortnightly inequality in the interval and height. The reference of the tide to the establishment is not, however, scientifically desirable, and it is better to determine the mean establishment, which is the mean interval from the moon's transit to high water at spring tide, and the age of the tide, which is the mean period from full moon and change of moon to spring tide.

Graphical treatment.

Graphical determination of establishment, etc.

Graphical prediction.

For these purposes the observations may be conveniently treated graphically.[3] An equally divided horizontal scale is taken to represent the twelve hours of the clock of civil time, regulated to the time of the port, or—more accurately—arranged always to show apparent time by being fast or slow by the equation of time; this time-scale represents the time-of-clock of the moon's transit, either upper or lower. The scale is perhaps most conveniently arranged in the order V, VI, . . , XII, I . . . IIII. Then each interval of time from transit to high water is set off as an ordinate above the corresponding time-of-clock of the moon's transit. A sweeping curve is drawn nearly through the tops of the ordinates, so as to cut off minor irregularities. Next along the same ordinates are set off lengths corresponding to the height of water at each high water. A second similar figure may be made for the interval and height at low water.[4] In the curve of high-water intervals the ordinate corresponding to XII is the establishment, since it gives the time of high water at full moon and change of moon. That ordinate of high-water intervals which is coincident with the greatest ordinate of high-water heights gives the mean establishment. Since the moon's transit falls about fifty minutes later on each day, in setting off a fortnight's observations there will be about five days for each four times-of-clock of the upper transit. Hence in these figures we may regard each division of the time-scale I to II, II to III, etc., as representing twenty-five hours instead of one hour. Then the distance from the greatest ordinate of high-water heights to XII is called the age of the tide. From these two figures the times and heights of high and low water may in general be predicted with fair approximation. We find the time-of-clock of the moon's upper or lower transit on the day, correct by the equation of time, read off the corresponding heights of high and low water from the figures, and the intervals being also read off are added to the time of the moon's transit and give the times of high and low water. At all ports there is, however, an irregularity of heights and intervals between successive tides, and in consequence of this the curves present more or less of a zigzag appearance. Where the zigzag is perceptible to the eye, the curves must be smoothed by drawing them so as to bisect the zigzags, because these diurnal inequalities will not present themselves similarly in the future. When, as in some equatorial ports, the diurnal tides are large, this method of tidal prediction fails.

Methods of Laplace, Lubbock, Whewell.

This method of working out observations of high and low water was not the earliest. In the *Mécanique Céleste*, bks. i. and v., Laplace treats a large mass of tidal observations by dividing them into classes depending on the configurations of the tide-generating bodies. Thus he separates the two syzygial tides at full moon and change of moon and divides them into equinoctial and solstitial tides. He takes into consideration the tides of several days embracing these configurations. He goes through the tides at quadratures on the same general plan. The effects of declination and parallax and the diurnal inequalities are similarly treated. Lubbock (*Phil. Trans.*, 1831 *sq.*) improved the method of Laplace by taking into account all the observed tides, and not merely those appertaining to certain configurations. He divided the observations into a number of classes. First the tides are separated into parcels, one for each month; then each parcel is sorted according to the hour of the moon's transit. Another classification is made according to declination; another according to parallax; and a last for the diurnal inequalities. This plan was followed in treating the tides of London, Brest, St. Helena, Plymouth, Portsmouth, and Sheerness. Whewell (*Phil. Trans.*, 1834 *sq.*) did much to reduce Lubbock's results to a mathematical form, and made a highly important advance by the introduction of graphical methods by means of curves. The method explained above is due to him. Airy remarks of Whewell's papers that they appear to be "the best specimens of reduction of new observations that we have ever seen."

VI. TIDAL INSTRUMENTS AND TIDAL PREDICTION.

§ 35. *General Remarks.*

Observation and prediction.

Practical tidal work is divisible into the three stages of observation, reduction of observations, and prediction. The simplest observation is that of the height of water on a graduated staff fixed in the sea, with such allowance as is possible made for wave-motion. It is far better, however, to sink a tube into the sea, into which the water penetrates through small holes. The wave-motion is thus annulled. In this calm water there lies a float, to which is attached a cord passing over a pulley and counterpoised at the end. The motion of the counterpoise against a scale is observed. In either case the observations may be made every hour, which is preferable, or the times and heights of high and low water may be noted. We have explained in § 34 the methods of reducing the latter kind of observation. Although more appropriate for rough observations, this method is susceptible of great accuracy when carefully used. It has been largely superseded by the harmonic method, but is still adhered to by the British Admiralty. In more careful observations than those of which we are speaking the tidal record is automatic and continuous; the reduction may be, and probably at some future time will be, mechanical; and the prediction is so already. We shall therefore devote some space to general descriptions of the three classes of instrument. The harmonic reductions are at present (1887) actually done numerically, and in chapter iv. we have indicated the nature of the arithmetical processes.

§ 36. *The Tide-Gauge.*

Tide-gauge.

The site for the erection of a tide-gauge depends on local circumstances. It should be placed so as to present a fair representation of the tidal oscillations of the surrounding area. A tank is generally provided, communicating by a channel with the sea at about 10 feet (more or less according to the prevalent surf) below the lowest low-water mark. In many cases on open coasts and frequently in estuaries the tank may be dispensed with. At any rate we suppose that water is provided rising and falling with the tide, without much wave-motion. The nature of the installation depends entirely on the circumstances of the case. A vertical pipe is fixed in the water in such a way as to admit it only through holes small enough to annul wave-motion and large enough to make no sensible retardation of its rise and fall in the pipe. The diameter of the pipe differs greatly in different instruments: sometimes that which we have described as the tank serves as the pipe, and sometimes the pipe alone dips into the sea. A cylindrical float, usually a hollow metallic box or a block of green-heart wood, hangs and floats in the pipe, and is of such density as just to sink without support. In Sir W. Thomson's gauge the float hangs by a fine platinum wire, in Newman's (used in India) by a metallic ribbon. In the latter a chain hangs at the bottom of the float of such weight that, whether the water be high or low, there is the same upward force on the float. It is necessary that the pull on the float should be constant, otherwise a systematic error is introduced between rising and falling water. The suspension wire is wrapped round a wheel, and imparts to it rotation proportional to the rise and fall of tide. By a simple gearing this wheel drives another, by which the range is reduced to any convenient extent. A fine wire wound on the final wheel of the train drags a pencil or pen up and down or to and fro proportionately to the tidal oscillations. The pencil is lightly pressed against a drum, which is driven by clockwork so as to make one revolution per day. The pen leaves its trace or tide-curve on paper wrapped round the drum. Generally, however, the paper is fixed to the drum, and the record of a fortnight may be taken without change of paper. An example of a tide-curve for Apollo Bunder, Bombay, from 1st to 15th January, 1884, is shown in Fig. 3. Sometimes the paper is in a long band, which the drum picks off from one coil and delivers on to another. The contact of the pen must be such that the work done in dragging it over the paper is small, otherwise a varying tension is thrown on to the float wire. Hence, if the friction is considerable, the float must be large.

---

[2] Waves with a period of from five to twenty minutes are very common, and appear to be analogous to the "seiches" of Geneva and other lakes. See Forel, *Bulletin Soc. Vaud. Sci. Nat.*, 1873, 1875, 1877, and 1879; *Ann. Chimie et Physique*, vol. ix., 1876; *Comptes Rendus*, 1879; *Arch. Sci., Ph., et Nat.*, *Geneva*, 1885; also Airy "On the Tides of Malta," *Phil. Trans.*, 1878, part i.

[3] For a numerical treatment, see *Directions for Reducing Tidal Observations*, by Commander Burdwood, R.N., London, 1876.

[4] An example of this kind of curve for the high-water heights for Bombay, drawn automatically by a tide-gauge, would be shown by joining all the high waters together (as in Fig. 3) by a continuous curve; and a similar curve may be constructed for the low waters. In this case, however, the hours of the clock are repeated twice over, so that the morning and evening tides occur in different halves of the figure, and the hours are not hours of the moon's transit, but the actual times of high water. It is obvious that the separation of the morning and evening tides prevents the occurrence of the zigzags referred to.

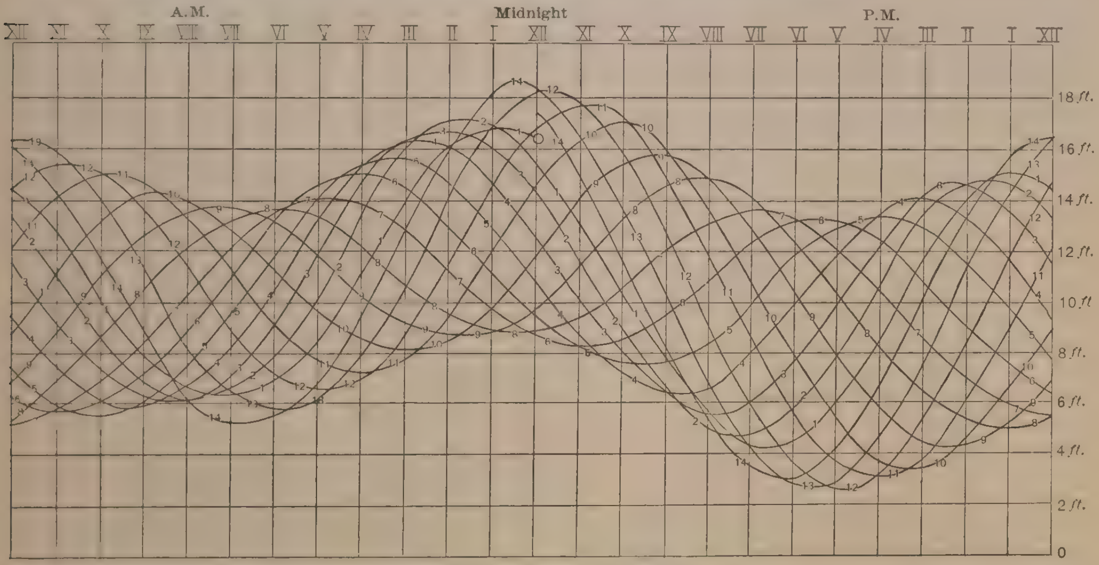

FIG. 3.—Tide-curve for Bombay from the beginning of the civil year 1884 to the midnight ending Jan. 14, 1884, or from 12h Dec. 31, 1883, to 12h Jan. 14, 1884, astronomical time.

Zero of Gauge.

The conditions necessary for a good tide-gauge appear to be better satisfied by Sir W. Thomson's than by any other; but, as his instrument is recent, other forms have been much more extensively used, and have worked well. The peculiarity of Thomson's tide-gauge is that, by giving the drum an inclination to the vertical, the pressure of the pen on the paper and on its guides is very delicately regulated to the minimum necessary for effecting the purpose. In other gauges the drum has been either vertical or horizontal, and the amount of friction has necessarily been considerably greater.[1]

§ 37. *The Harmonic Analyzer.*

Harmonic analyzer.

If a function H be expressed as a series of harmonic terms, and if one pair of these terms be A cos nt + B sin nt, then, if T be a multiple of the complete period $2\pi/n$, we have

$$A = \frac{2}{T}\int_0^T H \cos nt\, dt,\ B = \frac{2}{T}\int_0^T H \sin nt\, dt.$$

Thus a machine which will effect these integrations will give A and B. Such a machine has been invented by Prof. James Thomson and perfected by Sir W. Thomson. In Fig. 4 let TT′ be a circular table, capable of rotation about the inclined shaft s. Let S be a sphere touching the table anywhere along its horizontal diameter. Let C be a cylinder, of somewhat smaller diameter than the sphere, capable of rotation about a horizontal axis parallel to the table, and touching the sphere so that CS is parallel to TT′. Suppose that the point of contact of the sphere with the table is distant x from the centre of the table, and nearer to us than the shaft; then, when the shaft s and the table TT′ turn in such a direction that T rises from the paper and T′ goes below it, the sphere will turn in the direction of its arrow. If the radius of the sphere is a, and that of the cylinder b, then, when the table turns through a small angle $\delta\theta$, the sphere turns through $x\delta\theta/a$ and the cylinder through $x\delta\theta/b$. This angle vanishes if S touches the table at the centre, and is reversed if the sphere be moved across to the other side of the centre. Also whilst the table is turning the sphere may be rolled backwards and forwards without rubbing, and thus transmits motion from the table to the cylinder without slipping. Now suppose the turning of the table is so constrained that $\delta\theta = k \cos \psi d\psi$, whilst x is constrained to be equal to the arbitrarily varying quantity H. Then the total angle turned through by the cylinder, as the machine runs, is proportional to $\int$ H cos $\psi d\psi$. If we impart to the table a simple harmonic oscillatory motion, with a period proportional to the lunar half-day, whilst the sphere moves, relatively to the centre of the table, proportionately to the tide-heights on the same time-scale, then, at the end of a sufficient number of lunar days, we shall find that the total angle turned through by the cylinder is proportional to either the A or B component of the lunar semi-diurnal tide. An index, which points to a dial, may be fixed to the cylinder, so that the required result may be read off.

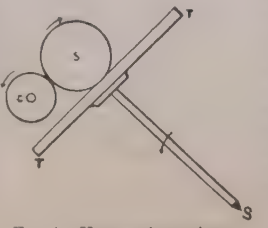

FIG. 4.—Harmonic analyzer.

In the harmonic analyzer the tide-curve diagram is wrapped on a drum, which is turned by one hand, whilst with the other a pointer is guided to follow the tide-curve. As the drum turns proportionately to mean solar time, appropriate gearing causes two tables to execute harmonic oscillations in phases at right angles, with lunar semi-diurnal period. At the same time a fork attached to the pointer guides the two spheres so that their distances from the centres of their tables are equal to the tide-height in the diagram. The indexes attached to the two cylinders give the two components of the lunar semi-diurnal tide, and the approximation improves the longer the tide-curve which is passed through the machine. Corresponding to each of the principal lunar and solar tides there is a pair of tables, spheres with guiding forks, and cylinders similarly geared, and there is another sphere and another table, which last always turns the same way and at the same rate as the drum, from which the mean height of water is determined. Such an instrument has been constructed under the supervision of Sir W. Thomson, but has not yet been put into practical use, so that we cannot say how it will compete with the arithmetical harmonic analysis. A similar, but less complex machine for the analysis of meteorological observations is in constant use in the Meteorological Office in London, and is found to work well.[1]

---

[1] For further details concerning the establishment of tide-gauges see Major Braid's *Manual of Tidal Observation*, London, 1887, and Sir W. Thomson, "On Tidal Instruments," in *Inst. Civ. Eng.*, vol. lxv. p. 10.

§ 38. *The Tide-Predicting Instrument.*

Tide-predicting instrument.

The first suggestion for instrumental prediction of tides was given, we believe, by Sir W. Thomson in 1872, and the instruments since made have been founded on the principles which he then laid down. Mr. Edward Roberts bore a very important part in the first practical realization of such a machine, and a tide-predictor was constructed by Légé for the Indian Government under his direction. Thomson's is the only instrument in Europe as yet in regular practical use for navigational purposes. It requires much skill and care in manipulation, and it has been ably worked by Mr. Roberts for the production of the Indian tide-tables ever since its completion. We refer the reader to Sir W. Thomson's paper on "Tidal Instruments," in *Inst. C.E.*, vol. lxv., and to the subsequent discussion, for a full account of the several instruments, and for details of the share borne by the various persons concerned in the realization of the idea.

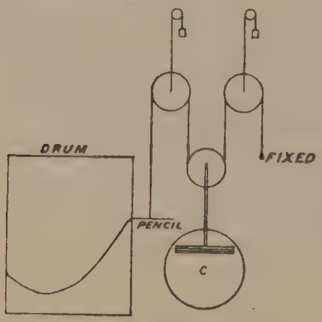

FIG. 5.—Tide-Predicting Instrument.

Fig. 5 illustrates diagrammatically the nature of the instrument. A cord passes over and under a succession of pulleys, being fixed at one end and having at the other a pen which touches a revolving drum. If all the pulleys but one be fixed, and if that one executes a simple harmonic motion up and down, the pen will execute the same motion with half amplitude. If a second pulley be now given an harmonic motion, the pen takes it up also with half amplitude. The same is true if all the pulleys are in harmonic motion. Thus the pen sums them all up, and leaves a trace on the revolving drum. When the drum and pulleys are so geared that the angular motion of the drum is proportional to mean solar time, whilst the harmonic motions of the pulleys correspond in range and phase to all the important lunar and solar tides, the trace on the drum is a tide-curve, from which a tide-table may be constructed. The harmonic motion of the pulley is given by an arrangement indicated only in the case of the lower pulley in the figure. The pulley frame has attached to its vertical portion a horizontal slot, in which slides a pin fixed to a wheel. Suppose that whilst the drum turns through 15° the wheel turns through 28.984°. Now a lunar day is 24.842 mean solar hours; hence as the drum turns through 15° × 24.842 the wheel turns through 24.842 × 28,984° or 720°. Thus, if the drum turns with an angular velocity proportional to solar time, the wheel turns with twice the angular velocity proportional to lunar time, and the pulley geared to the wheel executes lunar semi-diurnal harmonic oscillations. When the throw of the pin and its angular position on its wheel are adjusted so as to correspond with the range and phase of the observed lunar semi-diurnal tide, the oscillation of the pulley remains rigorously accurate for that tide for all future time, if the gearing be rigorously accurate, and with all needful accuracy for some ten years of tide with gearing as practically constructed. The upper pulleys have to be carefully counterpoised as indicated. It has not been found that any appreciable disturbance is caused by the inertia of the moving parts, even when the speed of working is high.

Tides on Indian instrument.

The predictor of the India Office takes about four hours to run off a year's tides, but greater speed seems attainable by modification in the gearing. The Indian instrument, in the store department at Lambeth, has pulleys for the following tides (see chap. iv.): M_2, M_4, M_6, K_1, S_1, S_2, O, N, P, K_2, Q, ν, J, L, λ, 2MS, 2SM, MS, Ssa, Sa.

§ 39. *Numerical Harmonic Analysis and Prediction.*

In chapter iv. we have discussed the application of the numerical harmonic method to a long series of hourly observations. An actual numerical example of this analysis, with modifications to render it applicable to a short series, such as a fortnight, is given in the *Admiralty Scientific Manual*, 1886, where also an example of the numerical and graphical prediction of the tides may be found. The formulæ used are those given in chapter v.

VII. PROGRESS OF THE TIDE-WAVE OVER THE SEA, AND THE TIDES OF THE BRITISH SEAS.

§ 40. *Meaning of Cotidal Lines.*

Cotidal lines.

Sufficient tidal data would of course give the state of the tide at every part of the world at the same instant of time, and if we were to follow the successive changes we should be able to picture mentally the motion of the wave over the ocean and the successive changes in its height. The data are, however, as yet very incomplete and only a rough scheme is possible. A map purporting to give the progress of the tide-wave is called a map of cotidal lines. For a perfect representation three series of maps would be required, one for the semi-diurnal tides, a second for the diurnal tides, and a third for the tides of long period. Each class of map would then show the progress of the wave for each configuration of the tide-generators. But as yet the only cotidal maps made are those for the mean semi-diurnal tide, and only for the configuration of new and full moon. The knowledge of the tides is not very accurate throughout the world, and therefore in the maps which we give it is assumed that the same interval elapses at all places between new and full moon and spring tide.

At spring tide, as we have seen in (87) and (88),

$$h_2 = (M + M_{,}) \cos 2 (\psi - \mu),$$

since $A - \mu_{,}$ becomes then equal to $-\mu$. As a rough approximation spring tide occurs when the moon's transit is at one o'clock at night or in the day. We only assume, however, that it occurs simultaneously everywhere. Now let τ be the Greenwich mean time of high water, and l the E. long in hours of the place of observation, then, the local time of high water being the time of the moon's transit plus the interval, and local time being Greenwich time plus E. long., we have $\tau = \mu/(\gamma - \sigma) - l = \frac{2}{29}\mu - l + 1^h$, where μ is in degrees. Therefore, if we draw over the ocean a succession of lines defined by equidistant integral values of the Greenwich time of high water, and if we neglect the separation of the moon from the sun in longitude in twelve hours, the successive lines will give the motion of the semi diurnal tide-wave in one hour.

§ 41. *Cotidal Lines of the World.*

No recent revisal of cotidal lines has been made with the aid of the great mass of tidal data which is now being accumulated, and we therefore reproduce (Fig. 6) the chart of the world prepared by Sir George Airy for his article on "Tides and Waves." The parts of the world for which data are wanting are omitted. The Roman numerals upon the cotidal lines denote the hour in Greenwich time of high water on the day of new or full moon. Airy remarks (§§ 575–584) that the cotidal lines of the North Atlantic are accurately drawn, that those of the South Atlantic are doubtful, and in the Pacific east of New Zealand are almost conjectural. The embodiment of recent observations in a cotidal chart would necessitate some modification of these statements.

Lines crowded near land.

When a free wave runs into shallow water it travels with less velocity and its height is increased. This is observable in the flexure and crowding of the cotidal lines near continents and oceanic islands, as, for example, about the Azores, the Bermudas, and the coast of South America. The velocity of the tide-wave gives good information as to the depth of the sea. In the North Sea it appears to travel at about 45 miles an hour, which corresponds to a depth of 140 feet, and we know that the depth along the deeper channel is greater and along the sides less than this. In the Atlantic the wave passes over 90° of latitude, from the southern to the northern one o'clock line, in twelve hours, that is at the rate of 520 miles an hour. If the Atlantic tide could be considered as a free wave generated by the Pacific tide, this velocity would correspond to a depth of 18,000 feet. Airy considers, however, that the Atlantic forms too large a basin to permit the neglect of the direct tidal action, and thinks that the tides of this ocean derive extremely little of their character from the Pacific.

---

[1] For further details, see Appendixes iii., iv., v., to Thomson and Tait's *Nat. Phil.*, 1879, vol. i., part i.; James Thomson, *Proc. Roy. Soc.*, vol. xxiv., 1876, p. 262, and (Sir. W. Thomson) pp. 269, 271; Sir W. Thomson, *Proc. Inst. C. E.*, vol. lxv.

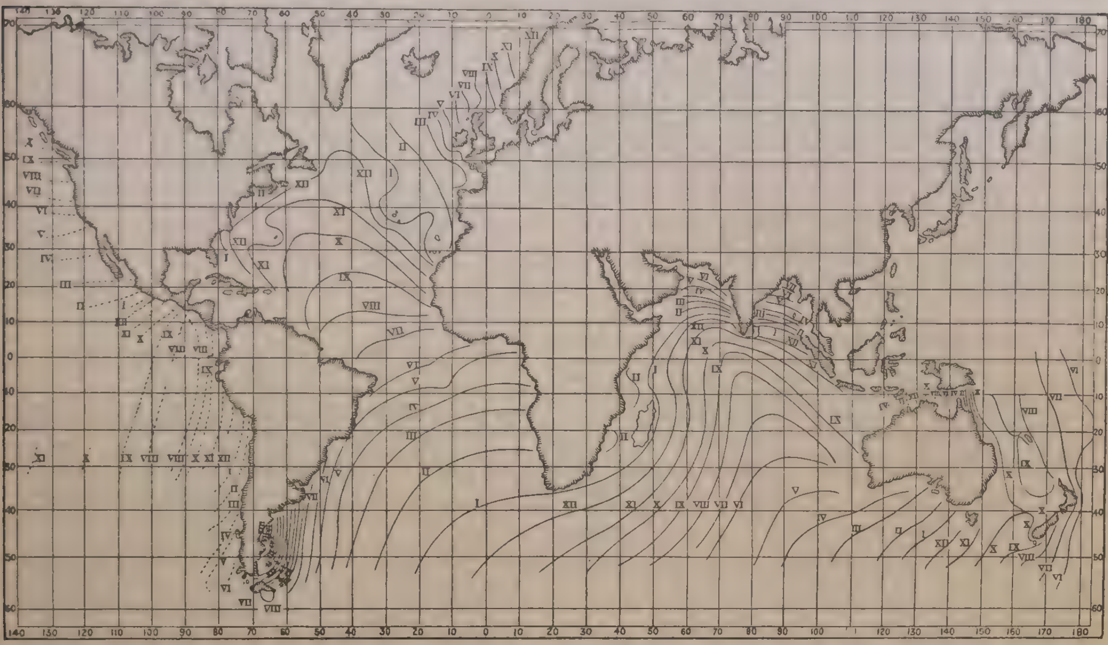

FIG. 6.—Cotidal lines of the world.

Sir G. B. Airy.

"There is another consideration," he says, "which must not be left out of sight. It is that, supposing the cotidal lines to be accurately what they profess to be—namely, the lines connecting all the points at which high water is simultaneous—they may, nevertheless, with a compound series of tide-waves, not at all represent the ridge of the tide-wave which actually runs over the ocean. Thus an eye at a great distance, capable of observing the swells of the tide-waves, might see one huge longitudinal ridge extending from the mouth of the Amazon to the sea beyond Iceland, making high water at one time from Cape de Verde to the North Cape, and at another time from Florida to Greenland, and another ridge transversal to the former, travelling from the coast of Guiana to the northern sea; and the cotidal lines which we have traced may depend simply on the combination of these waves. It does not appear likely that we can ever ascertain whether it is so or not; but it is certainly possible that the original waves may have these or similar forms; and if so it is vain for us to attempt entirely to explain the tides of the Atlantic."

He sums up the discussion of the chart by saying: "Upon the whole, therefore, we are driven to the conclusion that we cannot at all explain the cause of the form of the cotidal lines in the ocean, so far as they have been traced with any probability. And, supposing us to know with tolerable certainty those corresponding to the semi-diurnal tide, we cannot at all predict those which should hold for the diurnal tide."

§ 42. *Cotidal Lines of the British Seas.*

Fig. 7 shows the cotidal lines in the seas surrounding the British Islands. Here the lines refer to full moon and change of moon and not to spring tide. The small figures along different parts of the coast denote the extreme range of the tide in yards. This figure is from the same source as the preceding one, and we again reproduce a portion of Airy's remarks.

Sir G. B. Airy.

"The tides in the English Channel claim notice as having been the subject of careful examination by many persons, English and French. It appears that in the upper part of the Channel the water flows up the Channel nearly three hours after high water and runs down nearly three hours after low water (this continuance of the current after high water, if it lasts three hours, is called by sailors *tide-and-half-tide*; if it last one hour and a half, it is called *tide-and-quarter-tide*). On the English side of the Channel, especially opposite the entrance of bays, the directions of the currents

FIG. 7.—Cotidal lines of British seas.

turn in twelve hours in the same direction as the hands of a watch; on the French side they turn in the opposite direction. This is entirely in conformity with theory. The same laws are recognized as holding in the British [Bristol?] Channel, and in the German or North Sea near the Scotch and English coasts.

"With regard to the Irish Channel we have only to remark that there is a very great difference in the height of the tide on the different sides, the tide on the east side being considerably the greater. They are also greater in the northern part (north of Wicklow on one side, and of Bardsey Island on the other side) than in the southern part. Between Wexford and Wicklow they are very small.

"The tides of the German Sea present a very remarkable peculiarity. Along the eastern coast of England, as far as the mouth of the Thames, the tide-wave, coming from the Atlantic round the Orkney Islands, flows towards the south. Thus, on a certain day, it is high water in the Murray [Moray] Firth at eleven o'clock, at Berwick at two o'clock, at Flamborough Head at five o'clock, and so on to the entrance of the Thames. But on the Belgian and Dutch coasts immediately opposite, the tide-wave flows from the south towards the north. Thus, on the day that we have supposed, it will be high water off the Thames at eleven o'clock (the tide having travelled in twelve hours from the Murray Firth) and at Calais nearly at the same time; but at Ostend it will be at twelve, off The Hague at two, off the Helder at six, and so on.

"We believe that a complete explanation may be found in the arrangement of the great shoals of the North Sea. It must be remarked that (except within a very small distance of Norway) the North Sea is considerably deeper on the English side than on the German side; so much so that the tide-wave coming from the north runs into a deep bay of deep water, bounded on the west side by the Scotch and English coasts as far as Newcastle, and on the east side by the great Dogger Bank. As far as the latitude of Hull, the English side is still the deep one; and, though a species of channel through the shoal there allows an opening to the east, yet immediately on the south of it is the Wells Bank, which again contracts the deep channel to the English side. After this (that is, in the latitude of Yarmouth) the deep channel expands equally to both sides. It seems reasonable to conclude from this that the great set of north tide is on the English side of the North Sea, both between the Dogger Bank and England and between the Wells Bank and England (a branch stream of tide having been given off to the east between these two banks), and that any passage of tide-wave over these banks may be neglected. Now this view is supported in a remarkable degree by the tidal observations on two dangerous shoals called the Ower and Leman, lying between Cromer and the Wells Bank, but nearer to the latter. It appears that on these shoals the direction of the tide-current revolves in the same manner as the hands of a watch, proving conclusively that the Ower and Leman are on the left hand of the main stream of tide (supposing the face turned in the direction in which the tide proceeds), or are on its eastern border, and therefore that the central stream is still nearer to the coast of Norfolk. From a point not far south of this we may suppose the tide to diverge in a fan-shaped form over the uniformly deep Belgian Sea. Along the English coast the wave will flow to the south; but it will reach the whole of the Belgian and Dutch coast at the same instant; and, if this tide alone existed, we doubt not that the time of high water would be sensibly the same along the whole of that coast.

"But there is another tide of great magnitude, namely, that which comes from the English Channel through the Straits of Dover. This also diverges, we conceive, in a fan form, affecting the whole Belgian Sea: the western part turns into the estuary of the Thames; the eastern part runs along the Dutch coast, producing at successive times high water (even as combined with the North Sea tide) along successive points of that coast from Calais towards the Helder. And this we believe to be the complete explanation of the apparently opposite tide-currents. The branch tide of the North Sea running between the Dogger Bank and the Wells Bank will assist in propagating the tide along the German coast from the Helder towards the mouth of the Elbe. We have gone into some detail in this explanation for the purpose of showing the importance of considering the form of the bottom in explanations of specific tides.

"A set of observations has been made by Captain Hewett (at the point A, Fig. 7) on the depth and motion of the water at a strictly definite point a few miles south of the Wells Bank, near the middle of the Belgian Sea. The result was that the change of elevation of the surface was insensible, but that there was a considerable stream of tide alternately northeast and southwest (magnetic). The point in question corresponds pretty well to the intersection of the cotidal lines of nine o'clock of the North Sea tide and three o'clock of the English Channel tide (ordinary establishment), and these tides would therefore wholly or partially destroy each other as regards elevation. As regards the compound tide-stream, the greatest positive current from one tide will be combined with the greatest negative current of the other, and this will produce a stream whose direction agrees well with observation. At 3^h on the day of new moon, the North Sea tide would be running north (magnetic), and the English Channel tide would be running east, and therefore the compound current would be running northeast; at 9^h it would be running southwest. Both currents, and consequently the compound current, would cease at about 0^h, 6^h, etc., on the day of new moon; and, as the observations were made rather more than a day before new moon, the slack water would occur an hour or more before noon. The whole of this agrees well with the observations."

VIII. TIDAL DEFORMATION OF THE SOLID EARTH.

§ 43. *Elastic Tides.*

Elastic tides.

The tide-generating potential varies as the square of the distance from the earth's centre, and the corresponding forces act at every point throughout its mass. No solid matter possesses the property of absolute rigidity, and we must therefore admit the probable existence of tidal elastic deformation of the solid earth. The problem of finding the state of strain of an elastic sphere under given stresses was first solved by Lamé;[1] he made, however, but few physical deductions from his solution. An independent solution was found by Sir W. Thomson,[2] who drew some interesting conclusions concerning the earth.

His problem, in as far as it is now material, is as follows: Let a sphere, of radius a and density w, be made of elastic material whose bulk and rigidity moduli are k and n, and let it be subjected to forces due to a potential wr^2S_2 per unit volume, where S_2 is a surface spherical harmonic of the second order. Then it is required to find the strain of the sphere. We refer the reader to the original sources for the methods of solution applicable to spherical shells and to solid spheres. In order to write Thomson's solution we put r, λ, l for radius vector, latitude, and longitude, and ρ, μ, ν for the corresponding displacements. Then the solution is as follows:

$$\left.\begin{aligned}\rho&=\frac{w}{(19k+\frac{4}{3}n)n}[(8a^2-3r^2)k+\tfrac{2}{3}a^2n]rS_2\\ \mu&=\frac{w}{2(19k+\frac{4}{3}n)n}[(8a^2-5r^2)k+\tfrac{2}{3}(a^2-r^2)n]r\frac{dS_2}{d\lambda}\\ \nu&=\frac{w}{2(19k+\frac{4}{3}n)n}[(8a^2-5r^2)k+\tfrac{2}{3}(a^2-r^2)n]\\ &\qquad\frac{r}{\cos\lambda}\frac{dS_2}{dl}\end{aligned}\right\}\ldots(96).$$

For either tidal or rotational stresses

$$S_2=\tau(\sin^2\lambda-\tfrac{1}{3}),$$

in the case of tides $\tau=\frac{3}{2}m/c^3$, m and c being the moon's mass and distance, and in the case of rotation $\tau=-\frac{1}{2}\omega^2$, ω being the angular velocity about the polar axis. The equation to the surface is found by putting $r=a+\rho$, where in the expression for ρ we put $r=a$. Hence from (96) the form of surface is given by

$$r=a\left\{1+\frac{15wa^2}{19n}\left[1+\frac{\frac{6}{95}n/k}{1+\frac{4}{57}n/k}\right]\tau(\sin^2\lambda-\tfrac{1}{3})\right\}\ldots(97).$$

In most solids the bulk modulus is considerably larger than the rigidity modulus, and in this discussion it is sufficient to neglect n compared with k. With this approximation, the ellipticity e of the surface becomes

$$e=\frac{5wa^2}{19n}\tau\ldots\ldots\ldots\ldots\ldots\ldots(98).$$

Now suppose the sphere to be endued with the power of gravitation, and write

$$\mathfrak{r}=\frac{19n}{5wa^2},\ \mathfrak{g}=\frac{2}{5}\frac{g}{a}\ldots\ldots\ldots\ldots\ldots\ldots(99),$$

where g is gravity at the surface of the globe. Then, if there were no elasticity, the ellipticity would be given by $e=\tau/\mathfrak{g}$, and without gravitation by $e=\tau/\mathfrak{r}$. And it may be proved in several ways that, gravity and elasticity co-operating,

---

[2] Thomson and Tait, *Nat. Phil.*, §§ 732-737 and 833-842, or *Phil. Trans.*, pt. ii., 1863, p. 583.

$$e = \frac{\tau}{\mathfrak{r}+\mathfrak{g}} = \frac{\tau}{\mathfrak{g}} \cdot \frac{1}{1+\mathfrak{r}/\mathfrak{g}} \text{ ....(100).}$$

If n be the rigidity of steel, and if the globe have the size and mean density of the earth, $\mathfrak{r}/\mathfrak{g}=2$, and with the rigidity of glass $\mathfrak{r}/\mathfrak{g}=\frac{2}{3}$. Hence the ellipticity of an earth of steel under tide-generating force would be $\frac{1}{3}$ of that of a fluid earth, and the similar fraction for glass would be $\frac{3}{5}$. If an ocean be superposed on the globe, then, if the globe rises and falls with the tide as though it were fluid, there will obviously be no tide visible to an observer carried up and down with the solid; and with any degree of rigidity the visible tide will be the excess of the fluid tide above the solid tide. Hence on an earth with rigidity of steel the oceanic tides would be reduced to $\frac{2}{3}$, and with rigidity of glass to $\frac{2}{5}$ of the tides on a rigid earth.

§ 44. *Rigidity of the Earth.*

Rigidity of the earth.

Although the computation of oceanic tides is as yet impossible, it cannot be admitted that perfect rigidity in the earth would augment the tides in the proportion of 5 to 2, although they might perhaps be augmented in the proportion 4 to 3. Thus Thomson concludes that the earth's mass must have an effective rigidity at least as great as that of steel. If it were true, as was held until recently, that the earth is a fluid ball coated with a crust, that crust must be of fabulous rigidity to resist the tidal surgings of subjacent fluid. Hence we are led to the conclusion that far the larger portion of the earth's mass, if not all of it, is a solid of great rigidity. Up to the present time the argument by which the tides of long period were proved to have approximately their equilibrium height has generally been accepted without much doubt, but we have (§ 17) shown good cause for rejecting Laplace's argument, at least for a fortnightly tide. It appeared formerly that, from numerical data as to the heights of the tides of long period, we should be able to compute the actual effective rigidity of the earth's mass. But from § 18 we see that, although these tides remain incalculable, yet with such oceans as ours the tides of long period must conform much more nearly to the equilibrium laws than do the tides of short period. Thus a comparison of the observed heights of the tides of long period with the equilibrium law still remains of interest, although the evaluation of the earth's rigidity appears with present data unattainable. Acting on the old belief, Mr. G. H. Darwin has compared the lunar fortnightly and monthly tides, as observed for thirty-three years at various Indian and European ports, with the equilibrium theory, and has found that the tide-heights were about two-thirds of the equilibrium height.[1] From this the conclusion was drawn that the effective rigidity of the earth was as great as that of steel. Whilst, then, this precise comparison with the rigidity of steel falls to the ground, the investigation remains as an important confirmation of Thomson's conclusion as to the great effective rigidity of the earth. When extensive and accurate knowledge of the tides has been attained, the attempted evaluation of the rigidity may conceivably be possible, because there is a minute tide with a period of 18.6 years (§ 23, schedule [A, iii.]) of which Laplace's argument must hold good. Great accuracy will, however, be necessary, because the height of the tide at the equator only amounts to one-third of an inch, and a preliminary inquiry seems to show that there are other relatively considerable variations of sea-level arising from unexplained causes.[2]

Attempt to evalue rigidity by tides of long period.

The 19-yearly tide.

Weight of continents.

Sir W. Thomson's solution of the strain of an elastic sphere has been also used to determine what degree of strength the materials of the earth must have in order that the great continental plateaus and mountains may not sink in.[3] In another investigation it has been shown that local elastic yielding on the great coast-lines of continents may produce an augmentation of apparent tide in certain places on account of the flexure of the upper strata, when a great weight of water is added and subtracted from the adjacent oceanic area at high and low tide.[4] There is reason to believe that such flexure has actually been observed by a delicate form of level on the coast of the Bay of Biscay.[5]

§ 45. *Viscous and Elastico-Viscous Tides.*

Viscous and elastico-viscous tides.

It might be supposed that the earth is composed of a viscous fluid of great stiffness, or that it possesses an elasticity which breaks down under continued stress. Both these hypotheses have been considered, and the results are confirmatory of the conclusion that the earth is made of very stiff material.[6] These problems appear to have been worthy of attack, although the existence of measurable oceanic tides of long period negatives the adoption of the hypothesis of true viscosity, at least under stresses comparable with tide-generating forces.

If a sphere of radius a, density w, viscosity modulus v, be under the action of forces due to a potential per unit volume $wr^2S_2\cos nt$, so that n is the speed of the tide, the solution of the problem shows that the tide of the sphere is expressed by

$$\frac{aS_2}{\mathfrak{g}} \cos\varepsilon \cos(nt-\varepsilon) \text{.....................(101),}$$

where

$$\tan\varepsilon = n\frac{\mathfrak{r}}{\mathfrak{g}}, \quad \mathfrak{r} = \frac{19v}{5wa^2}, \quad \mathfrak{g} = \frac{2}{5}\frac{g}{a}.$$

Thus the tides of the viscous globe are to the equilibrium tides of a fluid globe as $\cos\varepsilon$ to unity, and there is a retardation ε/n of the time of high tide after the passage of the tide-generator over the meridian. Further, by arguments similar to that applied in the case of elastic tides, it is found that oceanic tides are reduced by the yielding in the proportion of $\sin\varepsilon$ to unity, and that there is an apparent acceleration of the time of high water by $(\frac{1}{2}\pi-\varepsilon)/n$. It appears by numerical calculation that, in order that the oceanic semi-diurnal tide may have a value equal to two-thirds of the full amount on a rigid globe, the stiffness of the globe must be about twenty thousand times as great as that of pitch at freezing temperature, when it is hard and brittle. We must here pass by the results of the hypothesis of an elasticity degrading under the influence of continued stress.

IX. TIDAL FRICTION.

§ 46. *General Explanation.*

General explanation of tidal friction.

The investigation of the tides of a viscous sphere has led us to the consideration of a frictionally retarded tide. The effects of tidal friction are of such general interest that we give a sketch of the principal results without the aid of mathematical symbols. In Fig. 8 the paper is supposed to be the plane of the orbit of a satellite M revolving in the direction of the arrow about the planet C, which rotates in the direction of the arrow about an axis perpendicular to the paper. The rotation of the planet is supposed to be more rapid than that of the satellite, so that the day is shorter than the month. Let us suppose that the planet is either entirely fluid, or has an ocean of such depth that it is high water under or nearly under the satellite. When there is no friction, with the satellite at m, the planet is elongated into the ellipsoidal shape shown, cutting the mean sphere, which is dotted. But, when there is friction in the fluid motion, the tide is retarded, and high tide occurs after the satellite has passed the meridian. Then, if we keep the same figure to represent the tidal elongation, the satellite must be at M, instead of at m. If we number the four quadrants as shown, the satellite must be in quadrant 1. The protuberance P is nearer to the satellite than P′, and the deficiency Q is further away than the deficiency

Planet's rotation retarded.

Satellite's velocity retarded.

Q′. Hence the resultant action of the planet on the satellite must be in some such direction as MN. The action of the satellite on the planet is equal and opposite, and the force in NM, not being through the planet's centre, must produce a retarding couple on the planet's rotation, the magnitude of which depends on the length of the arm CN. This tidal frictional couple varies as the height of the tide, and also depends on the satellite's distance; its intensity in fact varies as the square of the tide-generating force, and therefore as the inverse sixth power of the satellite's distance. Thus tidal friction must retard the planetary rotation. Let us now consider its effect on the satellite. If the force acting on M be resolved along and perpendicular to the direction CM, the perpendicular component tends to accelerate the satellite's velocity. It alone would carry the satellite further from C than it would be dragged back by the central force towards C. The satellite would describe a spiral, the coils of which would be very nearly circular and very nearly coincident. If now we resolve the central component force along CM tangentially and perpendicular to the spiral, the tangential component tends to retard the velocity of the satellite, whereas the disturbing force, already considered, tends to accelerate it. With the gravitational law of force between the two bodies the retardation must prevail over the acceleration.[1] The moment of momentum of the whole system remains unchanged, and that of the planetary rotation diminishes, so that the orbital moment of momentum must increase; now orbital moment of momentum increases with increasing distance and diminishing linear and angular velocity of the satellite. The action of tidal friction may appear somewhat paradoxical, but it is the exact converse of the acceleration of the linear and angular velocity and the diminution of distance of a satellite moving through a resisting medium. The latter result is generally more familiar than the action of tidal friction, and it may help the reader to realize the result in the present case. Tidal friction then diminishes planetary rotation, increases the satellite's distance, and diminishes the orbital angular velocity. The comparative rate of diminution of the two angular velocities is generally very different. If the satellite be close to the planet the rate of increase of the satellite's periodic time or month is large compared with the rate of increase of the period of planetary rotation or day; but if the satellite is far off the converse is true. Hence, if the satellite starts very near the planet, with the month a little longer than the day, as the satellite recedes the month soon increases, so that it contains many days. The number of days in the month attains a maximum and then diminishes. Finally the two angular velocities subside to a second identity, the day and month being identical and both very long.

We have supposed that the ocean is of such depth that the tides are direct; if, however, they are inverted, with low water under or nearly under the satellite, friction, instead of retarding, accelerates the tide; and it would be easy by drawing another figure to see that the whole of the above conclusions hold equally true with inverted tides.

§ 47. *Exact Investigation of the Secular Effects of Tidal Friction.*

Tidal friction.

The general conclusions of the last section are of such wide interest that we proceed to a rigorous discussion of the principal effects of tidal friction in the elementary case of the circular orbit. In order, however, to abridge the investigation we shall only consider the case when the planetary rotation is more rapid than the satellite's orbital motion.

Energy diminished by friction.

Suppose an attractive particle or satellite of mass m to be moving in a circular orbit, with an angular velocity Ω, round a planet of mass M, and suppose the planet to be rotating about an axis perpendicular to the plane of the orbit, with an angular velocity n; suppose, also, the mass of the planet to be partially or wholly imperfectly elastic or viscous, or that there are oceans on the surface of the planet; then the attraction of the satellite must produce a relative motion in the parts of the planet, and that motion must be subject to friction, or, in other words, there must be frictional tides of some sort or other. The system must accordingly be losing energy by friction, and its configuration must change in such a way that its whole energy diminishes. Such a system does not differ much from those of actual planets and satellites, and, therefore, the results deduced in this hypothetical case must agree pretty closely with the actual course of evolution, provided that time enough has been and will be given for such changes. Let C be the moment of inertia of the planet about its axis of rotation, r the distance of the satellite from the centre of the planet, h the resultant moment of momentum of the whole system, e the whole energy, both kinetic and potential, of the system. It is assumed that the figure of the planet and the distribution of its internal density are such that the attraction of the satellite causes no couple about any axis perpendicular to that of rotation. A special system of units of mass, length, and time will now be adopted such that the analytical results are reduced to their simplest forms. Let the unit of mass be $Mm/(M+m)$. Let the unit of length γ be such a distance that the moment of inertia of the planet about its axis of rotation may be equal to the moment of inertia of the planet and satellite, treated as particles, about their centre of inertia, when distant γ apart from one another. This condition gives

$$M\left(\frac{m\gamma}{M+m}\right)^2+m\left(\frac{M\gamma}{M+m}\right)^2=C;$$

whence
$$\gamma=\left\{\frac{C(M+m)}{Mm}\right\}^{\frac{1}{2}}.$$

Let the unit of time τ be the time in which the satellite revolves through 57.3° about the planet, when the satellite's radius vector is equal to γ. In this case $1/\tau$ is the satellite's orbital angular velocity, and by the law of periodic times we have

$$\tau^{2}\gamma^{3}=\mu(M+m),$$

where μ is the attraction between unit masses at unit distance. Then by substitution for γ

$$\tau=\left\{\frac{C^3(M+m)}{\mu^2(Mm)^3}\right\}^{\frac{1}{4}}.$$

Special units.

This system of units will be found to make the three following functions each equal to unity, viz., $\mu^{\frac{1}{2}}Mm(M+m)^{-\frac{1}{2}}$, μMm, and C. The units are in fact derived from the consideration that these functions are each to be unity. In the case of the earth and moon, if we take the moon's mass as $\frac{1}{82}$d of the earth's and the earth's moment of inertia as $\frac{1}{3}Ma^2$ (as is very nearly the case), it may easily be shown that the unit of mass is $\frac{1}{83}$ of the earth's mass, the unit of length 5.26 earth's radii or 33,506 kilomètres (20,807 miles), and the unit of time 2 hrs. 41 minutes. In these units the present angular velocity of the earth's diurnal rotation is expressed by .7044, and the moon's present radius vector by 11.454.

Moment of momentum.

The two bodies being supposed to revolve in circles about their common centre of inertia with an angular velocity Ω, the moment of momentum of orbital motion is

$$M\left(\frac{mr}{M+m}\right)^2\Omega+M\left(\frac{Mr}{M+m}\right)^2\Omega=\frac{Mm}{M+m}r^2\Omega.$$

Then, by the law of periodic times in a circular orbit,

$$\Omega^2r^3=\mu(M+m);$$

whence
$$\Omega r^2=\mu^{\frac{1}{2}}(M+m)^{\frac{1}{2}}r^{\frac{1}{2}}.$$

The moment of momentum of orbital motion

$$=\mu^{\frac{1}{2}}Mm(M+m)^{-\frac{1}{2}}r^{\frac{1}{2}},$$

and in the special units this is equal to $r^{\frac{1}{2}}$. The moment of momentum of the planet's rotation is Cn, and $C=1$ in the special units. Therefore

$$h=n+r^{\frac{1}{2}}\quad\ldots\ldots\ldots\ldots\ldots\ldots(102).$$

Since the moon's present radius vector is 11.454, it follows that the orbital momentum of the moon is 3.384. Adding to this the rotational momentum of the earth, which is .704, we obtain 4.088 for the total moment of momentum of the moon and earth. The ratio of the orbital to the rotational momentum is 4.80, so that the total moment of momentum of the system would, but for the obliquity of the ecliptic, be 5.80 times that of the earth's rotation. Again, the kinetic energy of orbital motion is

$$\tfrac{1}{2}M\left(\frac{mr}{M+m}\right)\Omega^2+\tfrac{1}{2}m\left(\frac{Mr}{M+m}\right)^2\Omega^2=\tfrac{1}{2}\frac{Mm}{M+m}r^2\Omega^2=\tfrac{1}{2}\frac{\mu Mm}{r}.$$

The kinetic energy of the planet's rotation is $\frac{1}{2}Cn^2$. The potential energy of the system is $-\mu Mm/r$. Adding the three energies together and transforming into the special units, we have

$$2e=n^2-1/r\quad\ldots\ldots\ldots\ldots\ldots\ldots(103).$$

Now let $x=r^{\frac{1}{2}}$, $y=n$, $Y=2e$.

It will be noticed that x, the moment of momentum of orbital motion, is equal to the square root of the satellite's distance from the planet. Then equations (102) and (103) become

$$h=y+x\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(104).$$

$$Y=y^2-1/x^3=(h-x)^2-1/x^2\ldots\ldots\ldots\ldots(105).$$

(104) is the equation of conservation of moment of momentum, or, shortly, the equation of momentum; (105) is the equation of energy.

Now consider a system started with given positive moment of momentum h; and we have all sorts of ways in which it may be started. If the two rotations be of opposite kinds, it is clear that we may start the system with any amount of energy however great, but the true maxima and minima of energy compatible with the given moment of momentum are supplied by $dY/dx=0$,

---

[1] This way of presenting the action of tidal friction is due to Professor Stokes.

Maximum and minimum energy.

or
$$x-h+1/x^3=0,$$
that is to say,
$$x^4-hx^3+1=0 \quad \text{..............} (106).$$

We shall presently see that this quartic has either two real roots and two imaginary, or all imaginary roots. The quartic may be derived from quite a different consideration, viz., by finding the condition under which the satellite may move round the planet so that the planet shall always show the same face to the satellite,—in fact, so that they move as parts of one rigid body. The condition is simply that the satellite's orbital angular velocity $\Omega=n$, the planet's angular velocity of rotation, or $y=1/x^3$, since $n=y$ and $r^{\frac{1}{2}}=\Omega^{-\frac{1}{3}}=x$. By substituting this value of y in the equation of momentum (104), we get as before $x^4-hx^3+1=0$. At present we have only obtained one result, viz., that, if with given moment of momentum it is possible to set the satellite and planet moving as a rigid body, it is possible to do so in two ways, and one of these ways requires a maximum amount of energy and the other a minimum; from this it is clear that one must be a rapid rotation with the satellite near the planet and the other a slow one with the satellite remote from the planet. In the three equations

No relative motion between satellite and planet when energy maximum or minimum.

$$h=y+x \quad \text{..................................} (107),$$
$$Y=(h-x)^2-1/x^2 \quad \text{.........................} (108),$$
$$x^3y=1 \quad \text{......................................} (109),$$

(107) is the equation of momentum, (108) that of energy, and (109) may be called the equation of rigidity, since it indicates that the two bodies move as though parts of one rigid body. To illustrate these equations geometrically, we may take as abscissa x, which is the moment of momentum of orbital motion, so that the axis of x may be called the axis of orbital momentum. Also, for equations (107) and (109) we may take as ordinate y, which is the moment of momentum of the planet's rotation, so that the axis of y may be called the axis of rotational momentum. For (108) we may take as ordinate Y, which is twice the energy of the system, so that the axis of Y may be called the axis of energy. Then, as it will be convenient to exhibit all three curves in the same figure, with a parallel axis of x, we must have the axis of energy identical with that of rotational momentum. It will not be necessary to consider the case where the resultant moment of momentum h is negative, because this would only be equivalent to reversing all the rotations; h is therefore to be taken as essentially positive. Then the line of momentum whose equation is (107) is a straight line inclined at 45° to either axis, having positive intercepts on both axes. The curve of rigidity whose equation is (109) is clearly of the same nature as a rectangular hyperbola, but it has a much more rapid rate of approach to the axis of orbital momentum than to that of rotational momentum. The intersections (if any) of the curve of rigidity with the line of momentum have abscissæ which are the two roots of the quartic $x^4-hx^3+1=0$. The quartic has, therefore, two real roots or all imaginary roots. Then, since $x=\sqrt{r}$, the intersection which is more remote from the origin indicates a configuration where the satellite is remote from the planet; the other gives the configuration where the satellite is closer to the planet. We have already learnt that these two correspond respectively to minimum and maximum energy. When x is very large, the equation to the curve of energy is $Y=(h-x)^2$, which is the equation to a parabola with a vertical axis parallel to Y and distant h from the origin, so that the axis of the parabola passes through the intersection of the line of momentum with the axis of orbital momentum. When x is very small, the equation becomes $Y=-1/x^2$. Hence the axis of Y is asymptotic on both sides to the curve of energy. Then, if the line of momentum intersects the curve of rigidity, the curve of energy has a maximum vertically underneath the point of intersection nearer the origin and a minimum underneath the point more remote. But, if there are no intersections, it has no maximum or minimum.

Equations of momentum, energy, and no relative motion.

Graphical illustration.

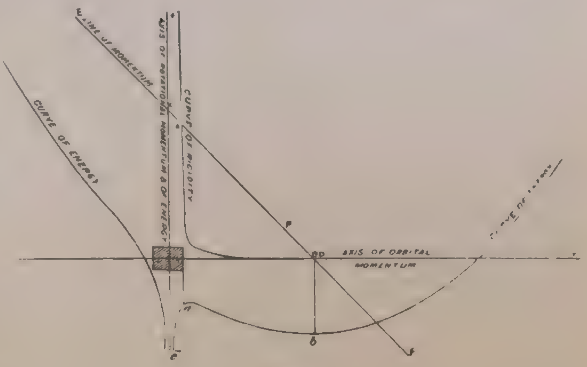

FIG. 9.

Fig. 9 shows these curves when drawn to scale for the case of the earth and moon, that is to say with $h=4$. The points a and b, which are the maximum and minimum of the curve of energy, are supposed to be on the same ordinates as A and B, the intersections of the curve of rigidity with the line of momentum. The intersection of the line of momentum with the axis of orbital momentum is denoted by D, but in a figure of this size it necessarily remains indistinguishable from B. As the zero of energy is quite arbitrary, the origin for the energy curve is displaced downwards, and this prevents the two curves from crossing one another in a confusing manner. On account of the limitation imposed we neglect the case where the quartic has no real roots. Every point of the line of momentum gives by its abscissa and ordinate the square root of the satellite's distance and the rotation of the planet, and the ordinate of the energy curve gives the energy corresponding to each distance of the satellite. Part of the figure has no physical meaning, for it is impossible for the satellite to move round the planet at a distance less than the sum of the radii of the planet and satellite. For example, the moon's diameter being about 2200 miles, and the earth's about 8000, the moon's distance cannot be less than 5100 miles. Accordingly a strip is marked off and shaded on each side of the vertical axis within which the figure has no physical meaning. The point P indicates the present configuration of the earth and moon. The curve of rigidity $x^3y=1$ is the same for all values of h, and by moving the line of momentum parallel to itself nearer to or further from the origin, we may represent all possible moments of momentum of the whole system. The smallest amount of moment of momentum with which it is possible to set the system moving as a rigid body, with centrifugal force enough to balance the mutual attraction, is when the line of momentum touches the curve of rigidity. The condition for this is clearly that the equation $x^4-hx^3+1=0$ should have equal roots. If it has equal roots, each root must be $\frac{3}{4}h$, and therefore

Least momentum for which no relative motion possible.

$$(\tfrac{3}{4}h)^4-h(\tfrac{3}{4}h)^3+1=0,$$

whence $h^4=4^4/3^3$ or $h=4/3^{\frac{3}{4}}=1.75$. The actual value of h for the moon and earth is about 4; hence, if the moon-earth system were started with less than $\frac{7}{16}$ of its actual moment of momentum, it would not be possible for the two bodies to move so that the earth should always show the same face to the moon. Again, if we travel along the line of momentum, there must be some point for which yx^3 is a maximum, and since $yx^3=n/\Omega$ there must be some point for which the number of planetary rotations is greatest during one revolution of the satellite; or, shortly, there must be some configuration for which there is a maximum number of days in the month. Now yx^3 is equal to $x^3(h-x)$, and this is a maximum when $x=\frac{3}{4}h$ and the maximum number of days in the month is $(\frac{3}{4}h)^3(h-\frac{3}{4}h)$ or $3^3h^4/4^4$; if h is equal to 4, as is nearly the case for the earth and moon, this becomes 27. Hence it follows that we now have very nearly the maximum number of days in the month. A more accurate investigation in a paper on the "Precession of a Viscous Spheroid" in *Phil. Trans.*, part i., 1879, showed that, taking account of solar tidal friction and the obliquity to the ecliptic, the maximum number of days is about 29, and that we have already passed through the phase of maximum. We will now consider the physical meaning of the figure. It is assumed that the resultant moment of momentum of the whole system corresponds to a positive rotation. Now imagine two points with the same abscissa, one on the momentum line and the other on the energy curve, and suppose the one on the energy curve to guide

Maximum number of days in month.

Discussion of figure.

that on the momentum line. Then, since we are supposing frictional tides to be raised on the planet, the energy must degrade, and however the two points are set initially the point on the energy curve must always slide down a slope, carrying with it the other point. Looking at the figure, we see that there are four slopes in the energy curve, two running down to the planet and two down to the minimum. There are, therefore, four ways in which the system may degrade, according to the way it was started; but we shall only consider one, that corresponding to the portion AB*ba* of the figure. For the part of the line of momentum AB the month is longer than the day, and this is the case with all known satellites except the nearer one of Mars. Now, if a satellite be placed in the condition A—that is to say, moving rapidly round a planet which always shows the same face to the satellite—the condition is clearly dynamically unstable, for the least disturbance will determine whether the system shall degrade down the slopes *ac* or *ab*—that is say, whether it falls into or recedes from the planet. If the equilibrium breaks down by the satellite receding, the recession will go on until the system has reached the state corresponding to B. It is clear that, if the intersection of the edge of the shaded strip with the line of momentum be identical with the point A, which indicates that the satellite is just touching the planet, then the two bodies are in effect parts of a single body in an unstable configuration. If, therefore, the moon was originally part of the earth, we should expect to find this identity. Now, in Fig. 9, drawn to scale to represent the earth and moon, there is so close an approach between the edge of the shaded band and the intersection of the line of momentum and curve of rigidity that it would be scarcely possible to distinguish them. Hence, there seems a probability that the two bodies once formed parts of a single one, which broke up in consequence of some kind of instability. This view is confirmed by the more detailed consideration of the case in the paper on the "Precession of a Viscous Spheroid," already referred to, and subsequent papers, in the *Philosophical Transactions* of the Royal Society.[1]

History of satellite as energy degrades.

§ 48. *Amount of Tidal Retardation of Earth's Rotation.*

Acceleration of moon's motion due to tidal friction.

With respect to the actual amount of retardation of the earth's rotation, we quote the following from Thomson and Tait's *Nat. Phil.* (1883), § 830.[2]

"In observational astronomy the earth's rotation serves as a time-keeper, and thus a retardation of terrestrial rotation will appear astronomically as an acceleration of the motion of the heavenly bodies. It is only in the case of the moon's motion that such an apparent acceleration can be possibly detected. Now, as Laplace first pointed out, there must be a slow variation in the moon's mean motion arising from the secular changes in the eccentricity of the earth's orbit around the sun. At the present time, and for several thousand years in the future, the variation in the moon's motion is and will be an acceleration. Laplace's theoretical calculation of the amount of that acceleration appeared to agree well with the results which were in his day accepted as representing the facts of observation. But in 1853 Adams showed that Laplace's reasoning was at fault, and that the numerical results of Damoiseau's and Plana's theories with reference to it consequently require to be sensibly altered. Hansen's theory of the secular acceleration is vitiated by an error of principle similar to that which affects the theories of Damoiseau and Plana: but, the mathematical process which he followed being different from theirs, he arrived at somewhat different results. From the erroneous theory Hansen found the value of 12.18″ for the coefficient of the term in the moon's mean longitude depending on the square of the time, the unit of time being a century; in a later computation given in his *Darlegung* he found the coefficient to be 12.56″.[3]

"In 1859 Adams communicated to Delaunay his final result, namely, that the coefficient of this term appears from a correctly conducted investigation to be 5.7″, so that at the end of a century the moon is 5.7″ before the position it would have had at the same time if its mean angular velocity had remained the same as at the beginning of the century. Delaunay verified this result, and added some further small terms which increased the coefficient from 5.7″ to 6.1″.

Various estimates of amount.

"Now, according to Airy, Hansen's value of the 'advance' represents very well the circumstances of the eclipses of Agathocles, Larissa, and Thales, but is if anything too small. Newcomb, on the other hand, is inclined from an elaborate discussion of the ancient eclipses to believe Hansen's value to be too large, and gives two competing values, viz, 8.4″ and 10.9″.[4]

Numerical result as to earth's rotation.

"In any case it follows that the value of the advance as theoretically deduced from all the causes, known up to the present time to be operative, is smaller than that which agrees with observation. In what follows 12″ is taken as the observational value of the advance, and 6″ as the explained part of this phenomenon. About the beginning of 1866 Delaunay suggested that the true explanation of the discrepancy might be a retardation of the earth's rotation by tidal friction. Using this hypothesis, and allowing for the consequent retardation of the moon's mean motion by tidal reaction, Adams, in an estimate which he has communicated to us, founded on the rough assumption that the parts of the earth's retardation due to solar and lunar tides are as the squares of the respective tide-generating forces, finds 22 sec. as the error by which the earth, regarded as a time-keeper, would in a century get behind a perfect clock rated at the beginning of the century. Thus at the end of a century a meridian of the earth is 330″ behind the position in which it would have been if the earth had continued to rotate with the same angular velocity which it had at the beginning of the century. . . .

Thomson's argument as to age of consolidation of earth.

Great uncertainty in preceding numbers.

"Whatever be the value of the retardation of the earth's rotation it is necessarily the result of several causes, of which tidal friction is almost certainly preponderant. If we accept Adams's estimate as applicable to the outcome of the various concurring causes, then, if the rate of retardation giving the integral effect were uniform, the earth as a time-keeper would be going slower by .22 of a second per year in the middle, and by .44 of a second per year at the end, than at the beginning of the century. The latter is $\frac{\cdot 1}{71.7 \times 10^6}$ of the present angular velocity; and, if the rate of retardation had been uniform during ten million centuries past, the earth must have been rotating faster by about one-seventh than at present, and the centrifugal force must have been greater in the proportion of 817^2 to 717^2 or of 67 to 51. If the consolidation took place then or earlier, the ellipticity of the upper layers must have been $\frac{1}{230}$ instead of about $\frac{1}{300}$, as it is at present. It must necessarily remain uncertain whether the earth would from time to time adjust itself completely to a figure of equilibrium adapted to the rotation. But it is clear that a want of complete adjustment would leave traces in a preponderance of land in equatorial regions. The existence of large continents and the great effective rigidity of the earth's mass render it improbable that the adjustments, if any, to the appropriate figure of equilibrium would be complete. The fact then that the continents are arranged along meridians rather than in an equatorial belt affords some degree of proof that the consolidation of the earth took place at a time when the diurnal rotation differed but little from its present value. It is probable, therefore, that the date of consolidation is considerably more recent than a thousand million years ago. It is proper, however, to add that Adams lays but little stress on the actual numerical values which have been used in this computation, and is of opinion that the amount of tidal retardation of the earth's rotation is quite uncertain."

§ 49. *Effects of Tidal Friction on the Elements of the Moon's Orbit and on the Earth's Rotation.*

It would be impossible within the limits of the present article to discuss completely the effects of tidal friction; we

---

[1] For further consideration of this subject see a series of papers by Mr. G. H. Darwin, in *Proceed.* and *Trans.* of the Royal Society from 1878 to 1881, and Appendix G (b) to part ii. vol i. of Thomson and Tait's *Nat. Phil.*, 1883.

[2] See also G. H. Darwin's *Address to Sect. A*, Brit. Assoc. meeting, 1886.

[3] "It appears not unusual for physical astronomers to use an abbreviated phraseology, for specifying accelerations, which needs explanation. Thus, when they speak of the secular acceleration being, *e.g.*, '12.56″ in a century,' they mean by 'acceleration' what is more properly 'the effect of the acceleration on the moon's mean longitude.' The correct unabbreviated statement is 'the acceleration is 25.12″ per century.' Thus Hansen's result is that in each century the mean motion of the moon is augmented by an angular velocity of 25.12″ per century, so that at the end of a century the mean longitude is greater by ½ of 25.12″ than it would have been had the moon's mean motion remained the same as it was at the beginning of the century. Considering how absurd it would be to speak of a falling body as experiencing an acceleration of 16 feet in a second, or of 64 feet in two seconds, and how false and inconvenient it is to speak of a watch being 20 seconds fast when it is 20 seconds in advance of where it ought to be, we venture to suggest that, to attain clearness and correctness without sacrifice of brevity, 'advance' be substituted for 'acceleration' in the ordinary astronomical phraseology."

Effects of tidal friction.

therefore confine ourselves to certain general considerations which throw light on the nature of those effects. We have in the preceding sections supposed that the planet's axis is perpendicular to the orbit of the satellite, and that the latter is circular; we shall now suppose the orbit to be oblique to the equator and eccentric, and shall also consider some of the effects of the solar perturbation of the moon-earth system. For the sake of brevity the planet will be called the earth, and the satellite the moon. The complete investigation was carried out on the hypothesis that the planet was a viscous spheroid, because this was the only theory of frictionally resisted tides which had been worked out. Although the results would be practically the same for any system of frictionally resisted tides, we shall speak below of the planet or earth as a viscous body.[1]

Obliquity of the ecliptic increases.

We shall show that if the tidal retardation be small the obliquity of the ecliptic increases, the earth's rotation is retarded, and the moon's distance and periodic time are increased. Fig. 10 represents the earth as seen from above the south pole, so that S is the pole and the outer circle the equator. The earth's rotation is in the direction of the curved arrow at S. The half of the inner circle which is drawn with a full line is a semi-small-circle of south latitude, and the dotted semi-circle is a semi-small-circle in the same north latitude. Generally dotted lines indicate parts of the figure which are below the plane of the paper. It will make the explanation somewhat simpler if we suppose the tides to be raised by a moon and anti-moon diametrically opposite to one another. Let M and M′ be the projections of the moon and anti-moon on to the terrestrial sphere. If the fluid in which the tides are raised were perfectly frictionless,[2] or if the earth were a perfect fluid or perfectly elastic, the apices of the tidal spheroid would be at M and M′. If, however, there is internal friction, due to any sort of viscosity, the tides will lag, and we may suppose the tidal apices to be at T and T′. Now suppose the tidal protuberances to be replaced by two equal heavy particles at T and T′, which are instantaneously rigidly connected with the earth. Then the attraction of the moon on T is greater than on T′, and that of the anti-moon on T′ is greater than on T. The resultant of these forces is clearly a pair of forces acting on the earth in the direction TM, T′M′. These forces clearly cause a couple about the axis in the equator, which lies in the same meridian as the moon and anti-moon. The direction of the couple is shown by the curved arrows at L, L′. If the effects of this couple be compounded with the existing rotation of the earth according to the principle of the gyroscope, the south pole S tends to approach M and the north pole to approach M′. Hence, supposing the moon to move in the ecliptic, the inclination of the earth's axis to the ecliptic diminishes, or the obliquity increases. Next the forces TM, T′M′ clearly produce, as in the simpler case considered above, a couple about the earth's polar axis, which tends to retard the diurnal rotation.

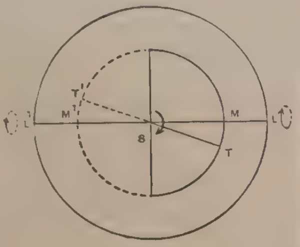

Fig. 10.

This general explanation remains a fair representation of the state of the case so long as the different harmonic constituents of the aggregate tide-wave do not suffer very different amounts of retardation; and this is the case so long as the viscosity is not great. The rigorous result for a viscous planet shows that in general the obliquity will increase, and it appears that, with small viscosity of the planet, if the period of the satellite be longer than two periods of rotation of the planet, the obliquity increases, and *vice versa*. Hence zero obliquity is only dynamically stable when the period of the satellite is less than two periods of the planet's rotation.

Inclination of plane of orbit generally decreases.

Suppose the motions of the planet and of its solitary satellite to be referred to the invariable plane of the system. The axis of resultant moment of momentum is normal to this plane, and the component rotations are that of the planet about its axis of figure and the orbital motion of the planet and satellite round their common centre of inertia; the axis of this latter rotation is clearly the normal to the satellite's orbit. Hence the normal to the orbit, the axis of resultant moment of momentum, and the planet's axis of rotation must always lie in one plane. From this it follows that the orbit and the planet's equator must necessarily have a common node on the invariable plane. If either of the component rotations alters in amount or direction, a corresponding change must take place in the other, such as will keep the resultant moment of momentum constant in direction and magnitude. It has been shown that the effect of tidal friction is to increase the distance of the satellite from the planet, and to transfer moment of momentum from that of planetary rotation to that of orbital motion. If, then, the direction of the planet's axis of rotation does not change, it follows that the normal to the lunar orbit must approach the axis of resultant moment of momentum. By drawing a series of parallelograms on the same diameter and keeping one side constant in direction, this may be easily seen to be true. This is equivalent to saying that the inclination of the satellite's orbit will decrease. But this decrease of inclination does not always necessarily take place, for the previous investigations show that another effect of tidal friction may be to increase the obliquity of the planet's equator to the invariable plane, or, in other words, to increase the inclination of the planet's axis to the axis of resultant moment of momentum. Now, if a parallelogram be drawn with a constant diameter, it is seen that by increasing the inclination of one of the sides to the diameter (and even decreasing its length) the inclination of the other side to the diameter may also be increased. The most favorable case for such a change is when the side whose inclination is increased is nearly as long as the diameter. From this it follows that the inclination of the satellite's orbit to the invariable plane may increase, and that it is most likely to increase, when the moment of momentum of planetary rotation is large compared with that of the orbital motion. The analytical solution of the problem agrees with these results, for it shows that if the viscosity of the planet be small the inclination of the orbit always diminishes, but if the viscosity be large, and if the satellite moves with a short periodic time (as estimated in rotations of the planet), the inclination of the orbit will increase. These results convey some idea of the physical causes which may have given rise to the present inclination of the lunar orbit to the ecliptic. For the analytical investigation shows that the inclination of the lunar orbit to a certain plane, which replaces the invariable plane when the solar attraction is introduced, was initially small, that it then increased to a maximum, and that it finally diminished and is still diminishing.

But the laws above referred to would, by themselves, afford a very unsatisfactory explanation of the inclination of the lunar orbit, because the sun's attraction is a matter of much importance. It has been found that, if the viscosity of the planet be small, the inclination of the orbit of the solitary satellite to the invariable plane will always diminish; but, when solar influence is introduced, the corresponding statement is not true with regard to the inclination of the lunar orbit to the proper plane, for during one part of the moon's history the inclination to the proper plane would have increased even if the viscosity of the earth had been small.

Eccentricity of orbit generally increases.

But it may decrease.

Consider a satellite revolving about a planet in an elliptic orbit, with a periodic time which is long compared with the period of rotation of the planet; and suppose that frictional tides are raised on the planet. The major axis of the tidal spheroid always points in advance of the satellite, and exercises on it a force which tends to accelerate its linear velocity. When the satellite is in perigee the tides are higher, and this disturbing force is greater than when the satellite is in apogee. The disturbing force may therefore be represented as a constant force, always tending to accelerate the motion of the satellite, and as a periodic force which accelerates in perigee and retards in apogee. The constant force causes a secular increase of the satellite's mean distance and a retardation of its mean motion. The accelerating force in perigee causes the satellite to swing out further than it would otherwise have done, so that when it comes round to apogee it is more remote from the planet. The retarding force in apogee acts exactly inversely, and diminishes the perigean distance. Thus, the apogean distance increases and the perigean distance diminishes, or, in other words, the eccentricity of the orbit increases. Now consider another case, and suppose the satellite's periodic time to be identical with that of the planet's rotation. Then, when the satellite is in perigee, it is moving faster than the planet rotates, and when in apogee it is moving slower; hence at apogee the tides lag, and at perigee they are accelerated. Now the lagging apogean tides give rise to an accelerating force on the satellite, and increase the perigean distance, whilst the accelerated perigean tides give rise to a retarding force, and decrease the apogean distance. Hence in this case the eccentricity of the orbit will diminish. It follows from these two results that there must be some intermediate periodic time of the satellite for which the eccentricity does not tend to vary.

---

[1] These explanations, together with other remarks, are to be found in the abstracts of Mr. G. H. Darwin's memoirs in *Proc. Roy. Soc.*, 1878 to 1881.

[2] We here suppose the tides not to be inverted. If they are inverted the conclusion is precisely the same.

But the preceding general explanation is in reality somewhat less satisfactory than it seems, because it does not make clear the existence of certain antagonistic influences, to which, however, we shall not refer. The rigorous result, for a viscous planet, shows that in general the eccentricity of the orbit will increase; but, if the obliquity of the planet's equator be nearly 90°, or if the viscosity be so great as to approach perfect rigidity, or if the periodic time of the satellite (measured in rotations of the planet) be short, the eccentricity will slowly diminish. When the viscosity is small the law of variation of eccentricity is very simple: if eleven periods of the satellite occupy a longer time than eighteen rotations of the planet, the eccentricity increases, and *vice versa*. Hence in the case of small viscosity a circular orbit is only dynamically stable if the eleven periods are shorter than the eighteen rotations.

X. COSMOGONIC SPECULATIONS FOUNDED ON TIDAL FRICTION.

§ 50. *History of the Earth and Moon.*

We shall not attempt to discuss the mathematical methods by which the complete history of a planet, attended by one or more satellites, is to be traced. The laws indicated in the preceding sections show that there is such a problem, and that it may be solved, and we refer to Mr. Darwin's papers for details (*Phil. Trans.*, 1879–81). It may be interesting, however, to give the various results of the investigation in the form of a sketch of the possible evolution of the earth and moon, followed by remarks on the other planetary systems and on the solar system as a whole.

Conjectural genesis of moon from earth.

We begin with a planet not very much more than 8000 miles in diameter, and probably partly solid, partly fluid, and partly gaseous. It is rotating about an axis inclined at about 11° or 12° to the normal to the ecliptic, with a period of from two to four hours, and is revolving about the sun with a period not much shorter than our present year. The rapidity of the planet's rotation causes so great a compression of its figure that it cannot continue to exist in an ellipsoidal form with stability; or else it is so nearly unstable that complete instability is induced by the solar tides. The planet then separates into two masses, the larger being the earth and the smaller the moon. It is not attempted to define the mode of separation, or to say whether the moon was initially a chain of meteorites. At any rate it must be assumed that the smaller mass became more or less conglomerated and finally fused into a spheroid, perhaps in consequence of impacts between its constituent meteorites, which were once part of the primeval planet. Up to this point the history is largely speculative, for the conditions of instability of a rotating mass of fluid have not yet been fully investigated. We now have the earth and moon nearly in contact with one another, and rotating nearly as though they were parts of one rigid body.[1] This is the system which was the subject of dynamical investigation.

Earth and moon subject of investigation.

As the two masses are not rigid, the attraction of each distorts the other; and, if they do not move rigorously with the same periodic time, each raises a tide in the other. Also the sun raises tides in both. In consequence of the frictional resistance to these tidal motions, such a system is dynamically unstable. If the moon had moved orbitally a little faster than the earth rotated, she must have fallen back into the earth; thus the existence of the moon compels us to believe that the equilibrium broke down by the moon revolving orbitally a little slower than the earth rotates. In consequence of the tidal friction the periodic times both of the moon (or the month) and of the earth's rotation (or the day) increase; but the month increases in length at a much greater rate than the day. At some early stage in the history of the system the moon was conglomerated into a spheroidal form, and acquired a rotation about an axis nearly parallel to that of the earth.

The moon.

The axial rotation of the moon is retarded by the attraction of the earth on the tides raised in the moon, and this retardation takes place at a far greater rate than the similar retardation of the earth's rotation. As soon as the moon rotates round her axis with twice the angular velocity with which she revolves in her orbit, the position of her axis of rotation (parallel with the earth's axis) becomes dynamically unstable. The obliquity of the lunar equator to the plane of the orbit increases, attains a maximum, and then diminishes. Meanwhile the lunar axial rotation is being reduced towards identity with the orbital motion. Finally, her equator is nearly coincident with the plane of the orbit, and the attraction of the earth on a tide, which degenerates into a permanent ellipticity of the lunar equator, causes her always to show the same face to the earth.

The earth and lunar orbit.

All this must have taken place early in the history of the earth, to which we now return. As the month increases in length the lunar orbit becomes eccentric, and the eccentricity reaches a maximum when the month occupies about a rotation and a half of the earth. The maximum of eccentricity is probably not large. After this the eccentricity diminishes. The plane of the lunar orbit is at first practically identical with the earth's equator, but as the moon recedes from the earth the sun's attraction begins to make itself felt. We must therefore introduce the conception of two ideal planes (here called the proper planes), to which the motion of the earth and moon must be referred. The lunar proper plane is at first inclined at a very small angle to the earth's proper plane, and the orbit and equator coincide with their respective proper planes. As soon as the earth rotates with twice the angular velocity with which the moon revolves in her orbit, a new instability sets in. The month is then about twelve of our present hours, and the day about six such hours in length. The inclinations of the lunar orbit and of the equator to their respective proper planes increase. That of the lunar orbit to its proper plane increases to a maximum of 6° or 7°, and ever after diminishes, that of the equator to its proper plane increases to a maximum of about 2° 45′, and ever after diminishes. The maximum inclination of the lunar orbit to its proper plane takes place when the day is a little less than nine of our present hours, and the month a little less than six of our present days. The maximum inclination of the equator to its proper plane takes place earlier than this. Whilst these changes have been going on the proper planes have been themselves changing in their positions relatively to one another and to the ecliptic. At first they were nearly coincident with one another and with the earth's equator, but they then open out, and the inclination of the lunar proper plane to the ecliptic continually diminishes, whilst that of the terrestrial proper plane continually increases. At some stage the earth became more rigid, and oceans were formed, so that oceanic tidal friction probably came to play a more important part than bodily tidal friction. If this be the case, the eccentricity of the orbit, after passing through a stationary phase, begins to increase again. We have now traced the system to a state in which the day and month are increasing, but at unequal rates, the inclination of the lunar proper plane to the ecliptic and of the orbit to the proper plane are diminishing, the inclination of the terrestrial proper plane to the ecliptic is increasing and of the equator to its proper plane is diminishing, and the eccentricity of the orbit is increasing. No new phase now supervenes and at length we have the system in its present configuration. The minimum time in which the changes from first to last can have taken place is 54,000,000 years.

Distortion of plastic planet.

There are other collateral results which must arise from a supposed primitive viscosity or plasticity of the earth's mass. For during this course of evolution the earth's mass must have suffered a screwing motion, so that the polar regions have travelled a little from west to east relatively to the equator. This affords a possible explanation of the north and south trend of our great continents. Also a large amount of heat has been generated by friction deep down in the earth; and some very small part of the observed increase of temperature in underground borings may be attributable to this cause. The preceding history might vary a little in detail according to the degree of viscosity which we attribute to the earth's mass, and according as oceanic tidal friction is or is not, now and in the more recent past, a more powerful cause of change than bodily tidal friction. The argument reposes on the imperfect rigidity of solids and on the internal friction of semi-solids and fluids; these are *veræ causæ*. Thus changes of the kind here discussed must be going on, and must have gone on in the past. And for this history of the earth and moon to be true throughout, it is only necessary to postulate a sufficient lapse of time, and that there is not enough matter diffused through space to materially resist the motions of the moon.

The theory postulates sufficient lapse of time.

---

[1] See criticisms by Mr. Nolan, *Genesis of Moon*, Melbourne, 1885; also *Nature*, 18th February, 1886.

and earth in perhaps 200,000,000 years. It seems hardly too much to say that, granting these two postulates, and the existence of a primeval planet, such as that above described, a system would necessarily be developed which would bear a strong resemblance to our own. A theory, reposing on *veræ causæ* which brings into quantitative correlation the lengths of the present day and month, the obliquity of the ecliptic, and the inclination and eccentricity of the lunar orbit should have claims to acceptance.

§ 51. *The Other Planetary Sub-systems.*

Other planetary sub-systems.

If this has been the evolution of the earth and moon, a similar process must have been going on elsewhere. So far we have only considered a single satellite and the sun, but the theory may of course be extended, with modifications, to planets attended by several satellites. We will now, therefore, consider some of the other members of the solar system. A large planet has much more energy of rotation to be destroyed, and moment of momentum to be redistributed, than a small one, and therefore a large planet ought to proceed in its evolution more slowly than a small one. Therefore we ought to find the larger planets less advanced than the smaller ones. The masses of such of the planets as have satellites are, in terms of the earth's mass, as follows: Mars $=\frac{1}{7}$; Jupiter $=340$; Saturn $=100$; Uranus $=17$; Neptune $=20$.

Mars.

Mars should therefore be furthest advanced in its evolution, and it is here alone in the whole system that we find a satellite moving orbitally faster than the planet rotates. This will also be the ultimate fate of our moon, because, after its orbital motion has been reduced to indentity with that of the earth's rotation, solar tidal friction will further reduce the earth's angular velocity; the tidal reaction on the moon will then be reversed, and the moon's orbital velocity will increase and her distance from the earth diminish. But, since the moon's mass is very large, she must recede to an enormous distance from the earth before this reversal takes place. Now the satellites of Mars are very small, and therefore they need only recede a very short distance from the planet before the reversal of tidal reaction. The periodic time of the satellite Deimos is $30^h\ 18^m$, and, as the period of rotation of Mars is $24^h\ 37^m$, Deimos must be still receding from Mars, but very slowly. The periodic time of the satellite Phobos is $7^h\ 39^m$; therefore it must be approaching Mars. It does not seem likely that it has ever been remote from the planet.[1] The eccentricities of the orbits of both satellites are small; that of Deimos is .0057 and that of Phobos .0066. If the viscosity of the planet be small, or if oceanic tidal friction be the principal cause of change, both eccentricities are diminishing; but, if the viscosity be large, both are increasing. As we have no means of knowing whether the eccentricities are increasing or diminishing, the larger eccentricity of the orbit of Phobos cannot be a fact of much importance either for or against the present views. But it must be admitted that it is a slightly unfavorable indication. The position of the proper plane of a satellite is determined by the periodic time of the satellite, the oblateness of the planet, and the sun's distance. The inclination of the orbit of a satellite to the proper plane is not determined by anything in the system. Hence it is only the inclination of the orbit which can afford any argument for or against the theory. The proper planes of both satellites are necessarily nearly coincident with the equator of the planet; but it is in accordance with the theory that the inclinations of the orbits to their respective proper planes should be small. Any change in the obliquity of the equator of Mars to the plane of his orbit must be entirely due to solar tides. The present obliquity is about 30°, and this points also to an advanced stage of evolution, at least if the axis of the planet was primitively at all nearly perpendicular to the ecliptic.

Jupiter.

We now come to the system of Jupiter. This enormous planet is still rotating in about ten hours; its axis is nearly perpendicular to the ecliptic; and three of its satellites revolve in seven days or less, whilst the fourth has a period of $16^d\ 16^h$. This system is obviously far less advanced than our own. The inclinations of the proper planes to Jupiter's equator are necessarily small, but the inclinations of the orbits to the proper planes appear to be very interesting from a theoretical point of view. They are in the case of the first satellite 0° 0′ 0″, in the case of the second 0° 27′ 50″, in that of the third 0° 12′ 20″, and in that of the fourth 0° 14′ 58″. We have shown above that the orbit of a satellite is first coincident with its proper plane, and that the inclination afterwards rises to a maximum and finally declines. If then we may assume, as seems reasonable, that the satellites are in stages of evolution corresponding to their distances from the planet, these inclinations accord well with the theory. The eccentricities of the orbits of the two inner satellites are insensible, those of the outer two small. This does not tell strongly either for or against the theory, because the history of the eccentricity depends considerably on the nature of the friction to which the tides are subject. Yet it on the whole agrees with the theory that the eccentricity should be greater in the more remote satellites. It appears that the satellites of Jupiter always present the same face to the planet, just as does our moon. This was to be expected.

Saturn.

The case of Saturn is not altogether so favorable to the theory. The extremely rapid rotation, the ring, and the short periodic time of the inner satellites point to an early stage of development; whilst the longer periodic time of the three outer satellites and the high obliquity of the equator indicate a later stage. Perhaps both views may be more or less correct, for successive shedding of satellites would impart a modern appearance to the system. It has probably been previously remarked that the Saturnian system bears a strong analogy to the solar system, Titan being analogous to Jupiter, Hyperion and Iapetus to Uranus and Neptune, and the inner satellites to the inner planets. Thus anything which aids us in forming a theory of the one system will throw light on the other. The details of the Saturnian system seem to be more or less favorable to the theory. The proper planes of the orbits (except that of Iapetus) are nearly in the plane of the ring, and the inclinations of all the orbits thereto appear not to be large. As the result of a careful series of observations made at Washington in 1873, Prof. Asaph Hall[2] finds that the eccentricities of the orbits of Mimas, Enceladus, Tethys, Dione, and Rhea are insensible, that of Titan is .0284, of Hyperion .1000, and that of Iapetus .0278. The satellite Iapetus appears always to present the same face to the planet.

Uranus and Neptune.

Concerning Uranus and Neptune there is not much to be said, as their systems are very little known; but their masses are much larger than that of the earth, and their satellites revolve with a short periodic time. The retrograde motion and high inclination of the satellites of Uranus are very remarkable. The theory of the inclination of the orbit has been based on an assumed smallness of inclination, and it is not very easy to see to what results investigation might lead if the inclination were large. It must be admitted, however, that the Uranian system points to the probability of the existence of a primitive planet, with retrograde rotation, or at least with a very large obliquity of equator.

It appears from this review that the other members of the solar system present some phenomena which are strikingly favorable to the tidal theory of evolution, and none which are absolutely condemnatory. We shall show in the following section that there are reasons why the tidal friction arising in the planetary systems cannot have had so much effect as in the case of the earth and moon. That the indications which we have just noted were not more marked, but yet seemed to exist, agrees well with this conclusion.

§ 52. *Influence of Tidal Friction on the Evolution of the Solar System.*

Solar system as a whole.

According to the nebular hypothesis, the planets and the satellites are portions detached from contracting nebulous masses. In the following discussion that hypothesis will be accepted in its main outline, and we shall examine what modifications are necessitated by the influence of tidal friction. It may be shown that the reaction of the tides raised in the sun by the planets must have had a very small influence in changing the dimensions of the planetary orbits round the sun. From a consideration of numerical data with regard to the solar system and the planetary sub-systems, it appears improbable that the planetary orbits have been sensibly enlarged by tidal friction since the origin of the several planets. But it is possible that some very small part of the eccentricities of the planetary orbits is due to this cause.

Planetary sub-systems.

From arguments similar to those advanced with regard to the solar system as a whole, it appears unlikely that the satellites of Mars, Jupiter, and Saturn originated very much nearer the present surfaces of the planets than we now observe them. But, the data being insufficient, we cannot feel sure that the alteration in the dimensions of the orbits of these satellites has not been considerable. It remains, however, nearly certain that they cannot have first originated almost in contact with the present surfaces of the planets, in the same way as in the preceding sketch (§ 50) has been shown to be probable with regard to the moon and earth. Numerical data concerning the distribution of moment of momentum in the several planetary sub-systems exhibit so striking a difference between the terrestrial system and those of the other planets that we should from this alone have grounds for believing that the modes of evolution have been considerably different. The difference appears to lie in the genesis of the moon close to the present surface of the planet, and we shall see below that solar tidal friction may be assigned as a reason to explain how it has happened that the terrestrial planet had contracted to nearly its present dimensions before the genesis of a satellite, but that this was not the case with the exterior planets. The efficiency of solar tidal friction is very much greater in its action on the nearer planets than on the further ones. The time, however, during which solar tidal friction has been operating on the external planets is probably much longer than the period of its efficiency for the interior ones, and a series of numbers proportional to the total amount of rotation destroyed in the several planets would present a far less rapid decrease as we recede from the sun than numbers simply expressive of the efficiency of tidal friction at the several planets. Nevertheless it must be admitted that the effect produced by solar tidal friction on Jupiter and Saturn has not been nearly so great as on the interior planets. And, as already stated, it is very improbable that so large an amount of momentum should have been destroyed as to materially affect the orbits of the planets round the sun.

---

[1] Mr. Nolan considers the theory inapplicable to the case of Mars; see *Nature*, 29th July, 1886.

Distribution of satellites amongst the planets.

Case of earth and moon different from others.

We will now examine how the differences of distance from the sun would be likely to affect the histories of the several planetary masses. According to the nebular hypothesis, a planetary nebula contracts, and rotates quicker as it contracts. The rapidity of the revolution causes it to become unstable, or perhaps an equatorial belt gradually detaches itself; it is immaterial which of these two really takes place. In either case the separation of that part of the mass which before the change had the greatest angular momentum permits the central portion to resume a planetary shape. The contraction and the increase of rotation proceed continually until another portion is detached, and so on. There thus recur at intervals a series of epochs of instability or of abnormal change. Now tidal friction must diminish the rate of increase of rotation due to contraction, and therefore if tidal friction and contraction are at work together the epochs of instability must recur more rarely than if contraction alone acted. If the tidal retardation is sufficiently great, the increase of rotation due to contraction will be so far counteracted as never to permit an epoch of instability to occur. Since the rate of retardation due to solar tidal friction decreases rapidly as we recede from the sun, these considerations accord with what we observe in the solar system. For Mercury and Venus have no satellites, and there is a progressive increase in the number of satellites as we recede from the sun. Moreover, the number of satellites is not directly connected with the mass of the planet, for Venus has nearly the same mass as the earth and has no satellite, and the earth has relatively by far the largest satellite of the whole system. Whether this be the true cause of the observed distribution of satellites amongst the planets or not, it is remarkable that the same cause also affords an explanation, as we shall now show, of that difference between the earth with the moon and the other planets with their satellites which has caused tidal friction to be the principal agent of change with the former but not with the latter. In the case of the contracting terrestrial mass we may suppose that there was for a long time nearly a balance between the retardation due to solar tidal friction and the acceleration due to contraction, and that it was not until the planetary mass had contracted to nearly its present dimensions that an epoch of instability could occur. It may also be noted that if there be two equal planetary masses which generate satellites, but under very different conditions as to the degree of condensation of the masses, the two satellites will be likely to differ in mass; we cannot of course tell which of the two planets would generate the larger satellite. Thus, if the genesis of the moon was deferred until a late epoch in the history of the terrestrial mass, the mass of the moon relatively to the earth would be likely to differ from the mass of other satellites relatively to their planets. If the contraction of the planetary mass be almost completed before the genesis of the satellite, tidal friction, due jointly to the satellite and to the sun, will thereafter be the great cause of change in the system; and thus the hypothesis that it is the sole cause of change will give an approximately accurate explanation of the motion of the planet and satellite at any subsequent time. We have already seen that the theory that tidal friction has been the ruling power in the evolution of the earth and moon co-ordinates the present motions of the two bodies and carries us back to an initial state when the moon first had a separate existence as a satellite; and the initial configuration of the two bodies is such that we are led to believe that the moon is a portion of the primitive earth detached by rapid rotation or other causes. There seems to be some reason to suppose that the earliest form in which the moon had a separate existence was as a ring or chain of meteorites; but this condition precedes that to which the dynamical investigation leads back.

Satellites of Mars.

Let us now turn to the other planetary sub-systems. The satellites of the larger planets revolve with short periodic times; this admits of a simple explanation, for the smallness of their masses would have prevented tidal friction from being a very efficient cause of change in the dimensions of their orbits, and the largeness of the planet's masses would have caused them to proceed slowly in their evolution. If the planets be formed from chains of meteorites or of nebulous matter, their rotation has arisen from the excess of orbital momentum of the exterior over that of the interior matter. As we have no means of knowing how broad the chain may have been in any case, nor how much it may have closed in on the sun in course of concentration, we are unable to compute the primitive angular momentum of a planet. A rigorous method of comparison of the primitive rotations of the several planets is thus wanting. If, however, the planets were formed under similar conditions, then we should expect to find the exterior planets now rotating more rapidly than the interior ones. On making allowance for the different degrees of concentration of the planets, this is the case. That the inner satellite of Mars revolves with a period of less than a third of the planet's rotation is perhaps the most remarkable fact in the solar system. The theory of tidal friction explains this perfectly; and this will be the ultimate fate of all satellites, because the solar tidal friction retards the planetary rotation without directly affecting the satellite's orbital motion. Numerical comparison shows that the efficiency of solar tidal friction in retarding the terrestrial and martian rotations is of about the same degree of importance, notwithstanding the much greater distance of the planet Mars. In the above discussion it will have been apparent that the earth and moon do actually differ from the other planets to such an extent as to permit tidal friction to have been the most important factor in their history.

Summary.

Limitation of time.

By an examination of the probable effects of solar tidal friction on a contracting planetary mass, we have been led to assign a cause for the observed distribution of satellites in the solar system, and this again has itself afforded an explanation of how it happened that the moon so originated that the tidal friction of the lunar tides in the earth should have been able to exercise so large an influence. We have endeavored not only to set forth the influence which tidal friction may have, and probably has, had in the history of the system, if sufficient time be granted, but also to point out what effects it cannot have produced. These investigations afford no grounds for the rejection of the nebular hypothesis; but, while they present evidence in favor of the main outlines of that theory, they introduce modifications of considerable importance. Tidal friction is a cause of change of which Laplace's theory took no account; and although the activity of that cause may be regarded as mainly belonging to a later period than the events described in the nebular hypothesis, yet it seems that its influence has been of great, and in one instance of even paramount importance in determining the present condition of the planets and their satellites. Throughout the whole of this discussion it has been supposed that sufficient time is at our disposal; Sir W. Thomson and others have, however, adduced reasoning which goes to show that the history of the solar system must be comprised within a period considerably less than a hundred million years.[1] It would perhaps be premature to accept this as the final and definite conclusion of science. If, however, it be confirmed, we shall only be permitted to accept the doctrine that tidal friction has effected considerable modification in the configuration of the moon and earth, and must reject the earlier portion of the history sketched above. (G. H. D.)

TABLE OF CONTENTS.

CHAP. I.—ON THE NATURE OF TIDES.
§ 1. Definition of tide.
§ 2. General description of tidal phenomena.
§ 3. General explanation of the cause of tides.
§ 4. Historical sketch.

CHAP. II. — TIDE-GENERATING FORCES.
§ 5. Investigation of tide-generating potential and forces.
§ 6. Form of equilibrium.
§ 7. Development of tide generating potential in terms of hour-angle and declination.
§ 8. Evaluation of tide-generating forces and lunar deflection of gravity.
§ 9. Correction to equilibrium theory for continents.

CHAP. III.—DYNAMICAL THEORY OF TIDES.
§ 10. Historical explanation.
§ 11. Equations of motion.
§ 12. Adaptation to forced oscillations.
§ 13. Preparation for solution.
§ 14. Diurnal tide.
§ 15. Semi-diurnal tide with variable depth.
§ 16. Semi-diurnal tide with uniform depth.
§ 17. Tides of long period; Laplace's argument from friction.
§ 18. Tides of long period in an ocean of uniform depth.
§ 19. Stability of the ocean.
§ 20. Precession and nutation.
§ 21. Some phenomena of tides in rivers.

CHAP. IV.—HARMONIC ANALYSIS.
§ 22. Methods of applying theory to practice.
§ 23. Development of equilibrium theory of tides in terms of the elements of the orbits.
§ 24. Meteorological tides, overtides, and compound tides.
§ 25. On the form of presentation of results of tidal observation.
§ 26. Numerical harmonic analysis for tides of short peroid.
§ 27. Harmonic analysis for tides of long period.

CHAP. V.—SYNTHETIC METHOD.
§ 28. On the method and notation.
§ 29. Semi-diurnal tides.
§ 30. Synthesis of solar and of lunar portions of the semi-diurnal tide.
§ 31. Synthesis of lunar and solar semi-diurnal tides.
§ 32. Diurnal tides.
§ 33. Explanation of tidal terms in common use: datum levels.
§ 34. On reduction of observations of high and low water.

CHAP. VI. — TIDAL INSTRUMENTS AND TIDAL PREDICTION.
§ 35. General remarks.
§ 36. The tide gauge.
§ 37. The harmonic analyzer.
§ 38. The tide-predicting instrument.
§ 39. Numerical harmonic analysis and prediction.

CHAP. VII.—PROGRESS OF THE TIDE WAVE OVER THE SEA AND THE TIDES OF THE BRITISH SEAS.
§ 40. Meaning of cotidal lines.
§ 41. Cotidal lines of the world.
§ 42 Cotidal lines of the British seas.

CHAP. VIII.—TIDAL DEFORMATION OF THE SOLID EARTH.
§ 43. Elastic tides.
§ 44. Rigidity of the earth.
§ 45. Viscous and elastico-viscous tides.

CHAP. IX.—TIDAL FRICTION.
§ 46. General explanation.
§ 47. Exact investigation of the secular effects of tidal friction.
§ 48. Amount of tidal retardation of earth's rotation.
§ 49. Effects of tidal friction on the elements of the moon's orbit and on the earth's rotation.

CHAP. X.—COSMOGONIC SPECULATIONS FOUNDED ON TIDAL FRICTION.
§ 50. History of the earth and moon.
§ 51. The other planetary subsystems.
§ 52. Influence of tidal friction on the evolution of the solar system.

TIDOR, or **TIDORE**, an island (0° 39′ N. lat. and 127° 23′ E. long.) of the East Indian Archipelago, off the west coast of JILOLO (*q.v.*) and south of Ternate, is nearly circular in form, and has an area of about 58 square miles. A volcano (5900 feet), now quiescent, rises in the centre and occupies nearly the whole of the island; its sides are densely covered with forests. The principal productions are sago, rice, cocoa-nuts, and bananas. The capital, Tidor, on the east coast, is a walled town and the seat of a sultan tributary to the Dutch. The population is estimated at 7500. Tidor, which is included in the residency of Ternate, is administered by a "controleur."

TIECK, **LUDWIG** (1773–1853), the most conspicuous figure of the German romantic school of literature, was born at Berlin on 31st May, 1773. His father, a ropemaker, was dry, sarcastic, and matter-of-fact; his mother, gentle and pious, with a leaning to mysticism. Tieck partook of both characteristics: half his work and half his genius seemed a skeptical commentary on the other half. He emancipated himself from the prosaic influence of his father's house by a passionate study of Shakespeare. After a brilliant career at school he repaired in 1792 to the university at Halle, and, returning to Berlin in 1794, devoted himself to authorship, in which he had already made experiments. As is so commonly the case with young writers of genius, his first tales (*Abdallah*, *William Lovell*) partook too largely of the melodramatic, and have little permanent value. But the romantic school of Germany, a movement comparable to the Lake school of England, was already in the air, and Tieck was deeply sensitive to its influence. He was strongly fascinated by two of its aspects in particular—the reaction in favor of German mediæval art and the revived interest in fairy tales and folk-lore in general. Inspired by his friend Wackenroder, a youth of pious ardor and most pious simplicity, he wrote his unfortunately unfinished romance *Sternbald's Travels*, a very gospel for the artist, at once the complement and the antitype of *Wilhelm Meister*. His studies in popular literature resulted in the entertaining adaptation of Blue Beard entitled *Peter Lebrecht*, and several kindred works. *Fair Eckbert*, his masterpiece, and the masterpiece of all romantic fiction, came to him he said by inspiration. He may well be believed: no artifice could have created the pervading sensation of dreamy solitude or the intense thrill of the catastrophe. The happy idea of dramatizing popular legend led to the production of a greatly improved *Blue Beard*, and subsequently of *Puss in Boots*, a satire on Kotzebue and Iffland, such an alliance of broad humor and dainty irony as we might expect to find in the lost Middle Comedy of Athens.

It might almost have been better if Tieck had continued to walk in his own way. His was a susceptible nature, too sensitive for perfect independence. In 1798 he made the acquaintance of the Schlegels, and was drawn into their circle. Novalis, undoubtedly the greatest genius of the romantic school was for a time a compensation to him for the death of Wackenroder, whose essays on art he edited with additions of his own. But Novalis himself soon died, and the influence of the Schlegel circle, with its bickerings and its "chopping and changing of ribs," was not wholly salutary either in a moral or a literary point of view. August Schlegel inspired Tieck with a passion for the Spanish drama. He also spent much time on a translation of *Don Quixote*, certainly a masterpiece, and rendered Ben Jonson's *Silent Woman*, having previously adapted *Volpone*. One important production of his own nevertheless belongs to this period, the romantic drama of *Genoveva*, enthusiastically admired by so clear-headed and impartial a judge as Bishop Thirlwall. He also produced his delightful miniature drama of *Little Red Riding Hood*, and was working with great spirit on *The Emperor Octavian* when he was suddenly attacked by rheumatic gout, which tormented him more or less for the remainder of his life. Between pain and unpleasant literary disputes his activity was long greatly impeded. The narrowness of his means also troubled him. He had married the daughter of Pastor Alberti, and, although he was an amiable man and nothing is alleged against his wife, his household does not seem to have been entirely comfortable. He lived alternately in Jena, Berlin, and Dresden, where he became very intimate with Steffens, and wrote his powerful but dismal tale, *The Runenberg*. *The Emperor Octavian* was completed in 1804, with less success than had been hoped. In the following year Tieck repaired to Italy, nominally to visit the baths of Pisa; but he made this medical injunction the plea for a long stay in the country. The effect of Italian scenery, plastic art, and new impressions in general was to wean him from much of the mysticism in which he had hitherto indulged, and to direct him to the criticism of life. The transition to his new manner is indicated by the additions to his former tales and dramas, which, after several years spent in wandering and in sickness, he published in 1812. *The Elves*, *The Philtre*, and *The Goblet* are tales, distinguished, the last two more especially, by brilliant coloring and elaborate art. *Fortunatus*, a drama in two parts, added in 1816, wants the spirit of its predecessors, but is pervaded by a quiet sarcastic humor exceedingly enjoyable. Plays and stories were set in a framework of æsthetic conversation, and the entire collection was entitled *Phantasus*. By this publication Tieck settled accounts with the romantic school, and could no more be regarded as its leader.

Tieck's power of original composition failed him for some years. He devoted himself especially to antiquarian and dramatic studies. In pursuance of the latter he visited England, saw Kemble and Kean on the stage, and renewed acquaintance with Coleridge, whom he had known in Italy. The friendship of Solger was highly important to him, and helped him to the clear definite principles of composition and criticism in which he had previously been deficient. The period of reflection gradually worked itself into a period of productiveness, beginning with his charming novelette of *The Pictures*, translated by Thirlwall. It was followed by a series of similar works extending over nearly twenty years, very unequal in value, but in their best examples belonging to a very high class of art. Their great peculiarity is the blending of narrative with disquisition and comment, so thoughtful and ingenious that, interesting as the action commonly is, the interruption is not resented. They have usually a strongly marked ironical element, as though the writer were only half in earnest, a self-criticism of which a great creative genius would have been incapable, but which bestows unusual piquancy on productions of the second order. *The Pictures*, already mentioned, is a fine instance of the masterly conduct of a story, and contains a very original figure, the shrewd, sottish, graceless old painter Eulenböck, who, with talent enough to have made a name and a fortune, gains a precarious livelihood by forging old masters. *The Betrothal*, also translated by Thirlwall, is a severe satire on hypocritical pietism. Among the best of the other novelettes in this style may be mentioned *The Travellers*, one of the most perfect specimens of the author's irony; *Luck brings Brains*, a fine study of the power of a weak character to rise to its opportunities when elevated by a sense of responsibility; and *The Superfluities of Life*, an anecdote delightfully told. *The Old Book* and *The Scarecrow*, two of the most fantastically imaginative, resolve themselves into literary satire. The motive of the latter was borrowed by Hawthorne in his *Mother Rigby's Pipe*. Of fictions with an historical basis, the most popular are those derived from the lives of poets—*A Poet's Life*, of which Shakespeare is the hero, and *A Poet's Death*, relating the sad history of Camoens. *The Revolt in the Cevennes* is an historical romance of considerable compass; but Tieck's masterpiece in this department is his *Witches' Sabbath*, a tale almost unparalleled in literature for its delineation of heart-breaking, hopeless misery. *The Young Carpenter* (1836, but commenced much earlier) can hardly be assigned to any of these classes. It has a strong affinity to *Wilhelm Meister*, and may be compared with *Sternbald*, both for its resemblance and its contrast. Finally, in *Vittoria Accorambona* (1840) Tieck takes yet another new departure, indicating affinities with the modern French school of fiction. The novel has been translated into English, but is probably best known to English readers by Mrs. Carlyle's half-earnest half-mocking admiration of the hero Bracciano, a Blue Beard on the highest principles, and her wish that she could have lived two hundred years before, "to have been—his mistress, not his wife."

These novels were all written at Dresden, where Tieck had settled in 1819. He enjoyed especial favor at court, took an active part in the direction of the royal theatre, and gained a new description of celebrity by his semi-public readings from dramatic poets in the court circle. According to the almost unanimous testimony of his hearers, he was the finest dramatic reader of his age. His daughter Dorothea, who united her father's literary talent to her grandmother's mystic piety, was of great assistance to him, especially in the translation of Shakespeare which passes under his name. Schlegel had translated seventeen plays. Tieck had undertaken to translate the remainder, and it has been generally supposed that he kept his word. In fact the translation was almost entirely executed by Dorothea Tieck and Count Wolf Baudissin, Tieck contributing hardly anything but his advice and his name. The truth slips out quite innocently in the pages of his biographer Köpke, and is fully told by Gustav Freytag (*Im Neuen Reich*, January, 1880). During his residence at Dresden he collected his critical writings, produced his excellent translation of the English dramatists anterior to Shakespeare, and edited the works of Novalis, Kleist, Lenz, and other contemporaries. In 1842 he accepted the invitation of Frederick William IV. to settle in Berlin, where he had already been to conduct the representation of the *Antigone* with Mendelssohn's music. He found himself but little in his element in the city of his birth, and the dramatic representations directed by him, including revivals of some of his own plays, were rarely successful. In 1851 his health failed entirely, and he withdrew altogether from the world. He died on 28th April, 1853.

Though not a writer of the highest rank, Tieck is nevertheless a most original genius, very unjustly neglected by his countrymen. The best of his compositions in the taste of the romantic school are absolute masterpieces; and his later productions, if imperfect, occupy a unique position in literature. He may be compared to Wieland, whom he decidedly surpasses, and to Ariosto, whom he would have more than rivalled if he had been capable of a great sustained effort. His susceptibility and self-distrust checked his genius, but at the same time gave it that peculiar ironic flavor which constitutes its special distinction. He is like an exquisite side dish, not sufficiently substantial for a full meal. The attempts to extract a moral significance from the stories in *Phantasus* seem entirely thrown away; the purpose of his later writings, when there is any, is always definite. Perhaps the soundest criticism upon him, at bottom, is Heine's in his *Romantic School*, though written at a time when it was his cue to show the works of that school as little quarter as possible. Carlyle's criticism is excellent, but only refers to the *Phantasus*.

The principal contribution to Tieck's biography is the delightful book of Rudolf Köpke (Leipsic, 1855), chiefly drawn from his oral communications and containing his opinions on a number of subjects. Particulars of his residence at Dresden, more especially of his connection with the theatre, are given in the memoirs of Friesen (Weimar, 1871). Tales from *Phantasus* have been translated in Carlyle's *Specimens of German Romance*, and are reprinted in his miscellanies. A greatly inferior version, in some places unscrupulously altered from Carlyle, was published in 1845 with an elaborate preface signed by J. A. F., who does not, however, appear to have been the translator. Several of Tieck's other works have been translated into English, but the only remarkable rendering is Bishop Thirlwall's of *The Pictures* and *The Betrothal*. A complete chronological list of his writings is appended to Köpke's work.

(R. G.)

TIEDEMANN, FRIEDRICH (1781–1861), German anatomist and physiologist, the son of a philosopher and psychologist of considerable repute, was born at Cassel on 23d August, 1781. He graduated in medicine at Marburg in 1804, but soon abandoned practice owing to disappointment at his failure to check his father's last illness. Repelled on the one hand by the brilliant but unsubstantial discourses of Schelling on the "Naturphilosophie," and attracted on the other hand by the practical skill and intelligence of the surgical anatomist Sömmering, he returned to the study of natural science. He betook himself to

Paris, and became an ardent follower of Cuvier. On his return to Germany he maintained the claims of patient and sober anatomical research against the prevalent speculations of the school of Oken (see OKEN and MORPHOLOGY), whose foremost antagonist he was long reckoned. His manifold labors in the field of Cuvierian anatomy cannot be recorded here; but his remarkable studies of the development of the human brain, as correlated with his father's studies on the development of intelligence, may be mentioned. He spent most of his life (from 1816) as professor of anatomy and physiology at Heidelberg, and died at Munich on 22d January, 1861.

T'IENTSIN is the largest commercial city in Chih-li, the metropolitan province of China. It is situated in 39° 7′ N. lat, and 117° 11′ E. long., at the junction of the Peiho and the Wan-ho, which is connected by the Grand Canal with the Yang-tsze-kiang. It is a prefectural city, and the residence of the viceroy of the province during a great portion of the year. The town is built on a vast alluvial plain which extends from the mountains beyond Peking to the sea, and through which the Peiho runs a circuitous course, making the distance by water from T'ientsin to the coast about 70 miles, as against 35 miles by road. The soil of the surrounding country being strongly impregnated with soda and nitre is not fertile, but produces sorghum and other coarse grains. The city walls are well built, though not always kept in good order, and measure about three quarters of a mile each way. As in all Chinese cities, the more wealthy inhabitants live in the suburbs, but even their houses have a mean appearance, being built mainly of mud or dried bricks. The streets are for the most part unpaved, and in wet weather are little better than quagmires. Some improvements have, however, been made in this respect of late. The city has always been a great commercial depôt. In 1885 the foreign imports amounted to £3,226.972 [$15,683,083.92], and the exports to £980,852 [$4,766,940.72], and 375 foreign vessels of 279,829 tons visited the port, tea to the value of about £904,496 [$4.395,850.56] being landed for carriage overland, *via* Kalgan and Kiachta, to Siberia. During the winter the river is frozen, so that communication has to be carried on overland to Chin-kiang on the Yang-tsze-kiang, to which point also a line of telegraph (now extended to Peking) was opened in 1881. The principal articles of import are shirtings, drills, T-cloths, jeans and twills, opium, woollens, steel, lead, needles, Japanese sea-weed, and sugar; and of export, skins, beans, and peas, straw braid, coal, dates, wool, tobacco, and rhubarb. The coal exported is brought from the Kaiping colliery to the east of T'ientsin; its output in 1885 was 181,039 tons, 54,976 tons more than in 1884. An experimental railway nearly two miles long has lately been constructed at T'ientsin.

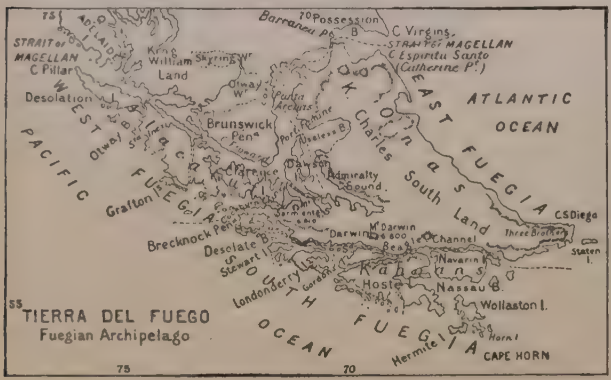
In 1853 T'ientsin was beseiged by an army of Taiping rebels, which had been detached from the main force at Nanking for the capture of Peking. The defences of T'ientsin, however, saved the capital, and the rebels were forced to retreat. Five years later Lord Elgin, accompanied by the representative of France, steamed up the Peiho, after having forced the barriers at Taku, and took peaceable possession of the town. Here the treaty of 1858 was signed. Two years later, in consequence of the treacherous attack made on the English plenipotentiary the preceding year at Taku, the city and suburbs were occupied by an allied English and French force, and were held for two years. The city was constituted an open port. On the establishment of Roman Catholic orphanages some years later the pretensions of the priests so irritated the people that on the occurrence of an epidemic in the schools they attacked the French and Russian establishments and murdered twenty of the foreign inmates, besides numbers of their native followers. The Chinese Government at once suppressed the riot, and sent a representative to Europe to apologize for the outbreak.

TIERNEY, GEORGE (1761–1830), an English Whig politician, was born at Gibraltar on 20th March, 1761, being the son of a wealthy merchant resident in Spain. He was sent to Peterhouse, Cambridge, where he took the degree of LL.D. in 1784, and was called to the bar; but, having inherited an ample fortune, he abandoned law and plunged into politics. He contested Colchester in 1788, when both candidates received the same number of votes, but Tierney was declared elected. He was, however, defeated in 1790. He sat for Southwark from 1796 to 1806, and then represented in turn Athlone (1806–7), Bandon (1807–12), Appleby (1812–18), and Knaresborough (1818–30). When Fox seceded from the House of Commons, Tierney became a prominent, if not the leading, opponent of Pitt's policy. It was perhaps for this reason that he was disliked by Fox. In 1797—such was the height of political passion at this epoch—Wilberforce noted in his diary that Tierney's conduct was "truly Jacobinical;" and in May, 1798, Pitt accused him of want of patriotism. As the words were not withdrawn, a duel ensued at Putney Heath on Sunday, 27th May, 1798; but neither combatant was injured. In 1803 Tierney, partly through gratitude for the peace which had been ratified with France and partly because Pitt was out of office, joined the ministry of Addington as treasurer of the navy, and was created a privy councillor; but this ill-advised step alienated many of his supporters among the middle classes, and offended most of the influential Whigs. On the death of Fox he joined (1806) the Grenville ministry as president of the board of control, with a seat in the cabinet, and thus brought himself once more into line with the Whigs. After the death of Ponsonby in 1817 Tierney became the recognized leader of the opposition in the House of Commons. In the neutral ministry of Canning, the place of master of the mint was held by him, and when Lord Goderich succeeded to the lead Tierney was admitted to the cabinet; but he was already suffering from ill-health and took little part in its deliberations. He died suddenly at Savile Row, London, on 25th January, 1830.

Tierney was a shrewd man of the world, with a natural aptitude for business. His powers of sarcasm were a cause of terror to his adversaries, and his presence in debate was much dreaded. His arguments were felicitous, and, though he never aimed at the highest flights of eloquence, his choice of language was the theme of constant admiration. Lord Lytton, in his poem of St. Stephen's, alludes to "Tierney's airy tread," and praises his "light and yet vigorous" attack, in which he inflicted, "with a placid smile," a fatal wound on his opponent.

TIERRA DEL FUEGO, a large archipelago at the southern extremity of South America, from which it is separated by Magellan Strait, at the narrows and other points scarcely a mile wide. The group lies between 52° 40′ and 55° 59′ S. lat. and 63° 30′ and 74° 35′ W. long., stretching nearly in a line with the Patagonian Andes for over 400 miles northwest and southeast, between Capes Pillar and Horn, and for about 270 miles west and east from Cape Pillar to Cape Espiritu Santo (Catherine Point) in the north; southwards it tapers to 120 miles between Capes Horn and St. Diego, the latter being continued eastwards to Staten Island, which is not usually included in the group. Although on ordinary maps this region presents to the eye a hopelessly confused aggregate of islands, channels, and fjord-like inlets, as if it had been submerged sufficiently to convert its deep valleys and gorges into marine passages, bays, and bights, it is nevertheless clearly disposed in three main sections, which may be conveniently named East, West, and South Fuegia.

East Fuegia consists of the single island of King Charles's South Land (eastern Tierra del Fuego), which is very much larger than all the rest of the group together, being considerably over 200 miles long from north to south. It obviously forms a southern extension of the Patagonian pampas, which it greatly resembles in its physical constitution, climate, flora, and fauna. The low-lying, flat or slightly rolling plains are covered with a rich growth of tall herbage, which is frequented by the rhea, guanaco, and other animals common to the adjoining mainland, and also peopled by a branch of the same Tehuelche (Patagonian) family. In the south a long peninsula projects westwards to the Pacific. This western limb assumes a mountainous character, Mount Darwin (6800 feet) being situated about midway on its south side and Mount Sarmiento (6900 or perhaps 7000 feet), the culminating point of the archipelago, much nearer the Pacific. Although generally supposed to be volcanic, this peak presents such extremely precipitous, in fact, almost vertical flanks that John Ball considers it more probably "a portion of the original rock skeleton that formed the axis of the Andean chain during the long ages that preceded the great volcanic outbursts that have covered the framework of the western side of South America."[1] This is altogether an alpine region with numerous snow-clad summits and glaciers descending down to the sea (Darwin).



Map of Tierra del Fuego.

Along the south side of East Fuegia flows Beagle Channel, about 55° S. lat., separating it from South Fuegia, which comprises the islands of Hoste, Navarin, Gordon, Londonderry, Stewart, Wollaston, and numerous islets, disposed in triangular form with the base on Beagle Channel and the apex at the rocky headland of Cape Horn. At its western end Beagle Channel takes the name of Darwin Sound, which leads to the Pacific at Londonderry and Stewart Islands. North of these lies Brecknock Peninsula, the westernmost extension of East Fuegia, cutting off South Fuegia from Clarence Island and Desolation Land, which with Dawson Island and numerous rocks and islets constitute West Fuegia. Desolation Land, so named by Cook, who supposed it to form a continuous mass stretching from the western entrance of Magellan Strait to Cockburn Channel, really consists of at least three, and possibly more islands, separated from each other by very narrow channels flowing between the Pacific and the western branch of Magellan Strait. The name Desolation has been reserved for the northern member of the group terminating at Cape Pillar; the one next to it has been called Santa Iñez; the other or others are still unnamed. When Ball passed through the strait, he was shown one of the narrow sounds "which have lately been ascertained to penetrate entirely through what used to be considered a single island" (*op. cit.*, p. 241).

Lying almost in a line with the main Andean axis, both West and South Fuegia are essentially highland regions, conforming in their general characteristics to the intervening western extension of East Fuegia. As compared with the great mass of the latter, they are everywhere extremely rugged and mountainous, having a mean elevation of not less than 3000 feet, a much moister climate, and arboreal instead of grassy vegetation. The isothermals of 32° Fahr. for July (winter) and 50° Fahr. for January (summer), with a mean annual temperature of 42° Fahr., show that tolerably mild winters are followed by cool summers, both seasons being accompanied by overcast skies, constant and sudden changes from fair to foul weather; whilst fogs, mists, rains, snows, and high winds (prevailing throughout the year) endanger the navigation of the intricate inland channels, and render the archipelago one of the dreariest regions on the globe.

A botanical parting line seems to be constituted by the range of hills running back of Punta Arenas along the east side of Brunswick Peninsula (which, although attached by a narrow neck of land to Patagonia, belongs physically to the insular domain), and terminating at Cape Froward (53° 54' S. lat.), the southernmost point of the American mainland. West and south of this line the pampas are replaced by lofty mountains clothed with a dense forest vegetation from the water's edge to heights of 1000 and 1200 feet, above which stretches a zone of peaty soil with stunted alpine plants as far as the snow line (3000 to 3500 feet). The forest species are chiefly an evergreen beech (*Fagus antarctica*, S.) and the winter bark (*Winteria aromatica*), also evergreen, with tall smooth stem and glossy leaves like the laurel. Wild celery, cress, cochlearia, and other anti-scorbutic plants occur on both sides of Magellan Strait, and the beech nourishes a large yellow mushroom, which, with the berries of a dwarf shrub, is the only vegetable food of the natives.

In West and South Fuegia the fauna is restricted mainly to two species of fox, a bat, rats, mice, the sea otter,[2] the penguin and other aquatic birds, and various cetaceans in the surrounding waters.

To the three geographical divisions correspond three well-marked ethnical groups,—the Onas of East, the Yahgans of South, and the Alacalufs of West Fuegia. The first are estimated to number 2000, the others 3000 each, making a total population of some 8000 for the whole archipelago. The Onas are Patagonians who have crossed the strait. The Alacalufs are also immigrants from the mainland, but probably they came at an earlier date, and from the western uplands, being apparently a branch of the Auca (Araucanian) race of the Patagonian and Chilian Cordilleras. They differ altogether in speech both from the Onas, with whom they come scarcely anywhere in contact, and from the Yahgans, who are the true aborigines of the archipelago. These last are in exclusive possession of South Fuegia, and also occupy the north side of Beagle Channel about Mount Darwin and further west. To them alone missionary enterprise has hitherto been extended, and the English station of Ushiwaya on Beagle Channel has for some years been the only centre of civilizing influences in the archipelago. As Lieutenant Bove of the Italian Antarctic expedition has made a special study of this branch,[3] they are much better known than either of the neighboring races. If they represent an earlier Araucanian immigration than that of the Alacalufs, their extremely low social state, on which all observers are unanimous, may be regarded as the result of degradation from a higher condition during their long sojourn in their present inhospitable environment. But it seems more probable that they are the direct descendants of the primitive race by which the archipelago has been occupied from a vastly remote period, as is shown by the very great number of kitchen-middens recently discovered on the coast. Although taller than the Negritoes of the eastern hemisphere (4 feet 10 inches to 5 feet 4 inches), the Yahgans present in some respects a more debased type, characterized by low brows, prominent zygomatic arches, large tumid lips, flat nose, loose wrinkled skin ("pelle grinzosa e cadente," says Bove), black restless eyes very wide apart, coarse black unkempt hair, and head and chest disproportionately large compared with the extremely slender and outwardly curved legs, conveying an impression of top-heaviness like that of the Akkas of equatorial Africa. Their mental qualities are on the same low level, as is indicated by the almost total absence of clothing under such inclement skies, by the brutal treatment of their women, who when old and useless are often eaten, by the lack of human affections or love of offspring, who in rough weather are thrown overboard (Dr. Fenton), either as a peace offering to the spirits of the storm or to lighten the canoe, and by many repulsive practices connected with their food and social habits. The tribal organization has not yet been reached, each family circle living apart and combining only in small groups against some common enemy, but recognizing no hereditary chief or even any temporary leader. Yet the missionaries, who have reduced the language to writing (Gospel of St. Luke, London, 1881), assert that it contains no less than 30,000 words, although the numerals stop at *five*, already a compound form (*cu-pash-pa*), and although the same word expresses both *hand* and *finger*. But they have obviously failed to distinguish between distinct terms and the endless grammatical intricacies in which this, like so many other rude forms of speech, is still involved.

[2] [The sea otter, *Enhydra lutris*, is not meant, see vol. xv. p. 446; but the fur-seal, *Otaria*, vol. xv. p. 450.—Am. Ed.]

[3] See Guido Cora's *Cosmos* for May, 1883.

Since 1881 the eastern portion of Fuegia (with Staten Island) has belonged to the Argentine Republic and the western to Chili. The boundary line, which is purely conventional, runs from Cape Espiritu Santo due south to Beagle Channel. Neither power has hitherto occupied any part of Fuegia, except Punta Arenas (Sandy Point) on the Patagonian side of Magellan Strait, where the Chilians have for some years maintained a convict and coaling station.

Fuegia was discovered by Magellan in 1520, when he sailed through the strait named after him, and called this region the "Land of Fire," either from now extinct volcanic flames, or much more probably from the fires kindled by the natives along parts of his course. In 1578 Drake first sighted the point which in 1616 was named Cape Hoorn (Anglicized Horn) by the Dutch navigators Lemaire and Schouten. In 1619 the brothers Nodal first circumnavigated the archipelago, which was afterwards visited at intervals by Wood and Narborough (1670), Gennes and Froger (1696), Byron (1764), Wallis and Carteret (1767), Cook (1768), and Weddell (1822). But no systematic exploration was attempted until the British Admiralty undertook a thorough survey of the whole group by King (1826–28) and Fitzroy (1831–36). The latter expedition (*Voyage of the "Beagle"*) was accompanied by Charles Darwin, then a young man. To these admirable surveys is due most of the present geographical terminology of the archipelago. Since then the work of exploration has been continued and nearly completed by Dumont d'Urville (1837), Charles Wilkes (1839), Parker Snow (1855), Bove (1883), and various English, American, and Roman Catholic missionaries.

TIFFIN, a city of the United States, in Seneca county (of which it is the county seat), Ohio, stands upon the Sandusky river, in 41° 7′ N. lat., 83° 11′ W. long., 42 miles southeast of Toledo. The city is situated in the midst of an agricultural region, for which it serves as a shipping and supply point, and has three railroads,—the Baltimore and Ohio, the Indiana, Bloomington, and Western, and the Northwestern Ohio. It is the seat of Heidelberg College, one of the minor educational institutions of the State. Tiffin had in 1880 a population of 7879, an increase of 2231 over that in 1870.

TIFLIS, capital of the province of the same name and of Russian Caucasia, is picturesquely situated (44° 48′ E. long., 41° 42′ N. lat.) at the foot of high mountains, on both banks of the river Kúr, some 500 feet above the level of the Black Sea. The heat in summer is excessive, owing to the confined position; but the surrounding hills (1350 to 2400 feet) shelter the town effectively from the cold winds of a generally severe winter. A large square, the cathedral, one or more handsome streets, gardens, bridges, many fine or neat buildings—among them the grand-ducal palace, the opera-house, and the museum—European shops, the club or circle, hotels, and public offices are evidence that Western civilization has not only penetrated but has long prevailed in this geographically remote town. Of its 54 churches 26 are Armenian, 2 Lutheran, and 1 Catholic. The (Sion) cathedral traces back its origin to the 5th century; but in the interval it has suffered much and often. Other churches date from the 14th and 15th centuries, the Armenian cathedral of Vank from 1480, and the Catholic church from the 14th century. Tiflis has two gymnasia and pro-gymnasia for boys and two for girls, and a number of other schools; several scientific societies, of which the Caucasian branch of the geographical society is well known; an astronomical and physical observatory; and a public library. The manufactures of the place are limited to a few cotton and silk factories, tanneries, soap-works, and brick-works. But the petty trades are largely developed; and the artisans of Tiflis (about 8000) are renowned as silversmiths, gunsmiths, and sword-makers. Since 1883 Tiflis has been in railway connection with Poti and Batum on the Black Sea and with Baku on the Caspian; but the line from Russia to Vladikavkaz has not yet crossed the main chain of the Caucasus. The trade is of great importance, as Tiflis is the chief centre for the import of raw silk and silken goods, raw cotton, carpets, and dried fruits from Persia, as well as from trans-Caucasia, while a variety of manufactured wares are imported from Russia. The foreign trade of trans-Caucasia with Asia, mostly carried on from Tiflis, in 1884 reached the value of £1,729,800 [$8,406,828] for exports, and £857,070 [$4,165,360.20] for imports. In 1883 the population numbered 104,024 as against 71,051 in summer 1865 and 60,085 in winter, exclusive of a garrison of 6800. Ethnologically the numbers are—Armenians 31,180, Georgians 14,787, and Russians 12,142, with an admixture of about 1200 Germans, 7150 Persians (in summer), 1500 Tatars, and some Jews and Greeks.

Many chroniclers and travellers have written about Tiflis. Perhaps one of the fullest accounts is contained in Brosset's edition of the *Description Géographique de la Géorgie* (St. Petersburg, 1842), by the illegitimate son of Wakhtang VI., king of Karthli, who became a pensioner of Peter the Great. English travellers since 1849 describe Tiflis in its main features much in the same terms. Lady Sheil, writing in 1849, calls it "most thriving, active, and bustling." Edward Eastwick (1860), estimating its population at 40,000 and the height of the mountains overhanging it at 3000 feet, represents the plain in which the city is situated to be so barren that "even the Kúr . . . imparts to it but a limited fertility." Mounsey (1866) speaks in warm terms of its social charms and the great hospitality of its inhabitants, and notes it as the seat of government for the "Caucasian provinces of Russia, headquarters of an army of 150,000 men, and the residence of the governor-general." In the old division of Tiflis three distinct towns were included,—Tiflis, Kal‘a (the fort), and Isni; subsequently Tiflis seems to have become known as Sáiyidábád, Kal‘a as Tiflis, and Isni as Aulabár. Kal‘a and Isni possessed citadels; that of the former contained the church of St. Nicholas and a royal palace, that of the latter the church of the Holy Virgin and the residence of the archimandrite. The town is now divided into quarters: the Russian (the finest of all), the German, the Armenian, and that in which are congregated Jews, Mohammedans, and the mass of Orientals. Tiflis can lay claim to a very considerable antiquity. In 455 the chieftain of Georgia, Wakhtang, transferred his capital from Mhtset to the warm springs of Tpilisi, where he erected several churches and a fort. In 570 the Persians took the place and made it the residence of their rulers, but retained it only for ten years. Tiflis underwent successive plunderings and devastations at the hands of the Greeks in 626, of one of the commanders of Omar in 731, of the Khazars in 828, and of the Saracens in 851. The Georgians, however, always managed to return to it and to keep it in their permanent possession. In the course of the succeeding centuries Tiflis fell repeatedly into Persian hands; and it was plundered by Timur about the end of the 14th century. Afterwards the Turks seized it several times, and towards the end of the 17th century the Lesghians made attacks upon it. In 1795, when the shah of Persia plundered Tiflis, Russia sent troops to its protection, and the Russian occupation became permanent in 1799.

TIGER. Although this name is often applied by settlers and sportsmen to several of the larger *Felidæ*, as the leopard of Africa and the jaguar of America, it should properly be restricted to the well-known striped species of Asia, *Felis tigris* of Linnæus, an animal which is only rivalled by the lion in size, strength, and ferocity among the cat-like beasts of prey. It is a true cat on a large scale, and possesses all the essential characters of the genus as defined in the article MAMMALIA (vol. xv. p. 440 *sq.*). It belongs to the section in which the pupil of the eye contracts under the stimulus of light into a round spot and not a vertical slit, and in which the hyoid bone is connected loosely with the skull by a long ligament, instead of by a continuous chain of bones. In these points it agrees with the lion and the leopard and differs from the common cat. Almost everything that is said in the article LION (vol. xiv. pp. 685–688) of the structure of the skeleton, teeth, and claws of that animal will apply equally well to the tiger, the difference between the two lying mainly in the skin and its coverings. There are, however, slight distinctions in the proportionate size of the lower teeth, the general form of the cranium, and the relative length of the nasal bones and ascending processes of the maxillaries by which the skull of the lion and tiger can be easily discriminated by the practiced observer.

Although examples of both species present considerable variations in size, and reliance cannot always be placed upon alleged dimensions, especially when taken from skins stripped from the body, it seems well ascertained that the length of the largest-sized Bengal tiger may exceed that of any lion. Larger specimens are certainly recorded, but 10 feet from the tip of the nose to the end of the tail is, according to Jerdon, an unusual length for a large male tiger. The female is somewhat smaller and has a lighter and narrower head. The tiger has no mane, but in old males the hair of the cheeks is rather long and spreading. The ground color of the upper and outer parts of the head, body, limbs, and tail is a bright rufous fawn, and these parts are beautifully marked with transverse stripes of a dark, almost black color. The markings vary much in different individuals, and even on the two sides of the same individual. The under parts of the body, the inside of the limbs, the cheeks, and a large spot over each eye are nearly white. The tigers which inhabit hotter regions, as Bengal and the south Asiatic islands, have shorter and smoother hair, and are more richly colored and distinctly striped than those of northern China and Siberia, in which the fur is longer, softer, and lighter colored.

Tiger (*Felis tigris*, Linn.).

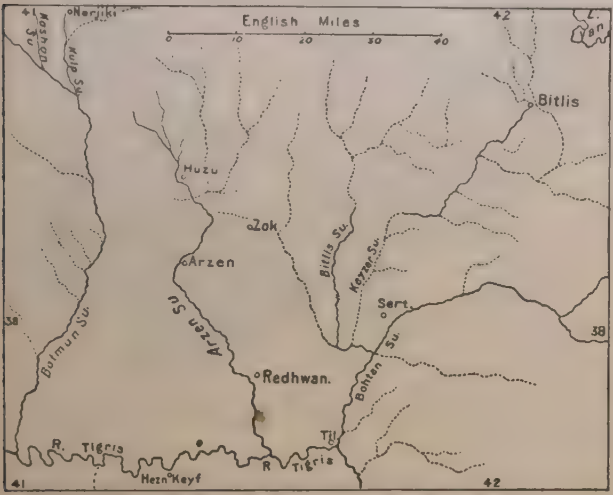
The tiger is exclusively Asiatic, but has a very wide range in that continent, having been found in almost all suitable localities south of a line drawn from the river Euphrates, passing along the southern shores of the Caspian and Sea of Aral by Lake Baikal to the Sea of Okhotsk. Its most northern range is the territory of the Amur, its most southern the islands of Sumatra, Java, and Bali. Westward it reaches to Turkish Georgia and eastward to the island of Saghalin. It is absent, however, from the great elevated plateau of Central Asia, nor does it inhabit Ceylon, Borneo, or the other islands of the Indo-Malayan Archipelago, except those named.

The principal food of the tiger in India is cattle, deer, wild hog, and pea-fowl, and occasionally human beings. The regular "man-eater" is generally an old tiger whose vigor is passed, and whose teeth are worn and defective; it takes up its abode in the neighborhood of a village, the population of which it finds an easier prey than the larger or wilder animals named above. Though chiefly affecting grassy plains or swamps, it is also found in forests, and seems to be fond of haunting the neighborhood of old ruins. As a rule, tigers do not climb trees; but when pressed by fear, as during an inundation, they have been known to do so. They take to the water readily and are good swimmers. The tigers of the Sundarbans (Ganges delta) continually swim from one island to the other to change their hunting-grounds for deer. The following extract from Sir J. Fayrer's *Royal Tiger of Bengal* (1875) may complete this notice of the tiger's habits.

> "The tigress gives birth to from two to five, even six cubs; but three is a frequent number. She is a most affectionate and attached mother, and generally guards and trains her young with the most watchful solicitude. They remain with her until nearly full-grown, or about the second year, when they are able to kill for themselves and begin life on their own account. Whilst they remain with her she is peculiarly vicious and aggressive, defending them with the greatest courage and energy, and when robbed of them is terrible in her rage; but she has been known to desert them when pressed, and even to eat them when starved. As soon as they begin to require other food than her milk, she kills for them, teaching them to do so for themselves by practicing on small animals, such as deer and young calves or pigs. At these times she is wanton and extravagant in her cruelty, killing apparently for the gratification of her ferocious and bloodthirsty nature, and perhaps to excite and instruct the young ones, and it is not until they are thoroughly capable of killing their own food that she separates from them. The young tigers are far more destructive than the old. They will kill three or four cows at a time, whilst the older and more experienced rarely kill more than one, and this at intervals of from three or four days to a week. For this purpose the tiger will leave its retreat in the dense jungle, proceed to the neighborhood of a village or gowrie, where cattle feed, and during the night will steal on and strike down a bullock, drag it into a secluded place, and then remain near the 'murrie,' or 'kill,' for several days, until it has eaten it, when it will proceed in search of a further supply, and, having found good hunting ground in the vicinity of a village or gowrie, continue its ravages, destroying one or two cows or buffaloes a week. It is very fond of the ordinary domestic cattle, which in the plains of India are generally weak, half-starved, under-sized creatures. One of these is easily struck down and carried or dragged off. The smaller buffaloes are also easily disposed of; but the buffalo bulls, and especially the wild ones, are formidable antagonists, and have often been known to beat the tiger off, and even to wound him seriously." (W. H. F.)

TIGER CAT. See OCELOT.

TIGRANES, or DIKRAN, a name borne by several kings of ancient Armenia. According to the legend of the Armenians, the first of these kings was the Tigranes who in Xenophon's romance appears as the schoolfellow of Cyrus, and to him they ascribe the foundation of Tigranocerta (Dikranagerd) on the Tigris. But in reality, as classical writers relate, this city was built by the first historical Tigranes of Armenia, variously known as TIGRANES II. and TIGRANES I., for whose history see PERSIA, vol. xviii. p. 606 *sq.* His son Tigranes is known by his rebellion against his father (PERSIA, *ut supra*). TIGRANES III. (II.), grandson of Tigranes II. (I.), had a short reign, which he owed to a revolution at home and the favor of Augustus. He came to the throne in 20 B.C., having previously been an exile at Rome. Tigranes IV. (III.) was seated on the throne by the Parthians (PERSIA, p. 611). For Tigranes V. (c. 60 A.D.), a great-grandson on his mother's side of Herod the Great, see PERSIA, vol. xviii. p. 613.



Map showing the tributaries of the Tigris.

TIGRIS,[1] the shorter of the two large rivers rising in the highlands of Armenia and Kurdịstan, and (when turned southward) running each its own independent course to the Persian Gulf. Like the Euphrates, the Tigris rises from two principal sources, of which the western and more distant—in 38° 10′ N. lat. and about 39° 20′ E. long.—is a little south of Lake Giuljek, in a peninsula formed by the Euphrates, and some 2 or 3 miles only from the channel of that river. The names and sources of the different streams forming the Western Tigris—or that part of the upper river which runs, roughly speaking, from Diarbekr to the junction with the Eastern Tigris, about 50 miles north-northwest from Jezíra Ibn Omar—are given by Consul Taylor as the Arganeh M'adan and the Dibeneh Su, uniting at Ammaneh castle; the Ambar Su, rising at Heyni; the Batman Su, formed by the Kulp, the Kaushan, and the Sarum, rising north and northwest of Nerjiki; and the Khuzu or Huzu and the Arzen-Redhwan or Yezid Khaneh Su. Of the Eastern Tigris the chief tributaries are the Bohtan Su and its feeder the Bitlis (which receives the Keyzer or Shirwan), the Möx, the Shattak, the Chamkari, and the Sarhal Su. Of these the most northerly points may be found on the Kulp or Dibeneh Su about 38° 40′ N. lat. and the most easterly on the Shattak in 42° 50′ E. long.

After the junction of the eastern and western branches (see the accompanying map) the river pursues a winding course, generally southeast, for about 800 miles, *via* Mosul and Baghdad, to the point of union with the Euphrates at Kurna, whence it becomes known as the Shattu 'l-Arab, and falls into the sea some 70 miles farther down. Between Mosul and Baghdad the Tigris receives from its left the Great and the Little Zab and other tributaries from the Kurdish Mountains. Below the confluence of the latter it is joined by the Diyála, also from the left, while on the right canals and watercourses connect it more or less directly with the Euphrates, which in the vicinity of Baghdad it approaches to within 30 or 35 miles. The Tigris is navigable for light freight-bearing steamers up to Baghdad, and for vessels of lighter draught to 20 miles below Mosul, but thence to Diarbekr only for rafts. "But owing to the rapidity of the current the traffic is all down stream, carried on mainly by a primitive style of craft, which is broken up at Baghdad and transported by camels back to Mosul. The journey between these points occupies three or four days during the floods and from twelve to fourteen at other times."

TILBURG, or **TILBORG**, a town of Holland, in the province of North Brabant, 13 miles to the east-southeast of Breda, contains numerous and extensive woollen factories, employing from 5000 to 6000 persons, and also some calico-printing establishments. It has the usual public buildings, including four Roman Catholic churches, a Reformed church, and a synagogue, but none of architectural or historical interest. The population in 1879 was 28,390 and in 1887 32,016.

TILDEN, SAMUEL JONES (1814–1886),[2] American statesman, was born at New Lebanon, New York, on the 9th of February, 1814. He studied at Yale and at the University of New York, but ill-health prevented him from finishing his course. He studied law and rose rapidly to the first rank at the New York bar. From boyhood he had had a fondness for politics, but had sacrificed it to the practice of law. After 1860 he drifted into New York State politics, and became chairman of the Democratic State Committee in 1866. The Tweed "ring" in New York city dreaded him, and in 1869 attempted to remove him from his chairmanship. Tilden then became the soul of the legal attacks upon the "ring," and worked for the removal of the corrupt judges who were their tools; and in the "ring trials" he accomplished the mathematical feat of ascertaining and demonstrating from bank-books the principle on which the spoils had been divided. In 1874 he was elected governor of the State by the Democrats. For years another "ring" had been making money out of the State canals. This, too, Tilden succeeded in breaking up. In 1876 the National Democratic Convention nominated him for the presidency, the Republicans nominating Governor Hayes of Ohio. The result was the disputed election of 1876–77, when each party secured about the same number of electors outside of the three Southern states of Florida, South Carolina, and Louisiana. The Democrats had a majority in these States; but the returning boards, by rejecting votes which they believed had been obtained by fraud or intimidation, gave their States to the Republicans. Two sets of certificates were therefore sent to Washington, and as no provision had been made in the United States constitution for a dispute of this kind there was no power authorized to decide between the two parties. In this emergency Tilden consented to the appointment of an extra-constitutional body, an "electoral commission," to decide disputed cases, the decisions of which were to hold good unless reversed by concurrent vote of the two houses. The commission decided all the cases in favor of the Republican candidates, and Tilden was defeated. He continued in retirement until his death, which took place at Greystone, New York, on 4th August, 1886.

---

[1] The Tigris is the Hiddekel of the Bible, the Diḳlat or Idiḳlat of the cuneiform monuments. The old Persian form Tigrá ("swift as an arrow"), whence Tigris, seems to be connected etymologically with these names. The modern Arabic name is Dijla (Aramaic Deḳlath, Diglā).

[2] [Governor Tilden's ancestors came from Kent county in England, and first settled in Massachusetts. At eighteen he wrote an article for the *Albany Argus* in the interests of the Regency and the Democrats of the State, then threatened by a coalition of Anti-Masons and nascent Whigs, which was attributed to Martin Van Buren. Graduated with the class of 1837 at the University of New York, he soon began writing political articles for the press on financial and economical topics, some of which were circulated as campaign documents. In 1844, three years after his admission to the bar, he established the *Morning News*, and edited it through the presidential campaign of that year. A brief experience in the Assembly of his native State was followed by absorption into his profession, where he became distinguished for rare analytical powers and "perfection of method" in handling witnesses. At the outbreak of the civil war he was accused of disloyalty to the Union, but he warned a friend that the South "must not expect Northern Democrats to hold the government while they were whipping it," and avowed that he would sustain President Lincoln in case of hostilities, as he would have done President Jackson. He claimed to have given sixteen months "to the total surrender of professional business" to the overthrow of the Tweed ring, and his account of the steps then taken he published under the title *The New York City Ring, Its Origin, Maturity, and Fall* (1873). These efforts secured him the Democratic nomination for the governorship of his State in the following year, when he defeated General Dix by a large majority. An accurate account of his disputed election to the presidency, and of the Electoral Commission which gave judgment for Hayes, may be found in vol. xx. p. 907. The decision turned upon a single electoral vote, and the zealous Democratic governor of Oregon, holding that one of the Republican electors chosen in that State was disqualified, gave a certificate to his Democratic opponent Out of this conduct grew the notorious "cipher-despatches" design to uphold the Oregon governor, and Tilden did not escape the suspicion of being implicated in them. He refused to be a candidate in the ensuing presidential contest, and passed the rest of his days in retirement at Greystone, his country seat near Yonkers, N. Y. Of the vast estate which he had accumulated he devised the greater part, over $4,000,000, to trustees for public uses, and they have incorporated to establish with this money a public library in New York city.

In the vituperations of political life he was accused of inadequate returns of his taxable income, with sharp practices as a corporation counsellor, and with subtle indirections in the pursuit of official place; but he rarely deigned to notice the charges. In his retirement he was the recognized leader and adviser of the Democratic party, and his reforming services to the city and State of New York have secured him the undisputed reputation of an able and useful statesman. See his *Writings and Speeches*, by John Bigelow (2 vols., 1885), and a campaign life of him by T. P. Cook, 1876.—AM. ED.]

TILES (Saxon *tigel*, connected with Lat. *tegula*) are used for a great variety of architectural purposes, such as covering roofs, floors, and walls, and are made of many different materials.

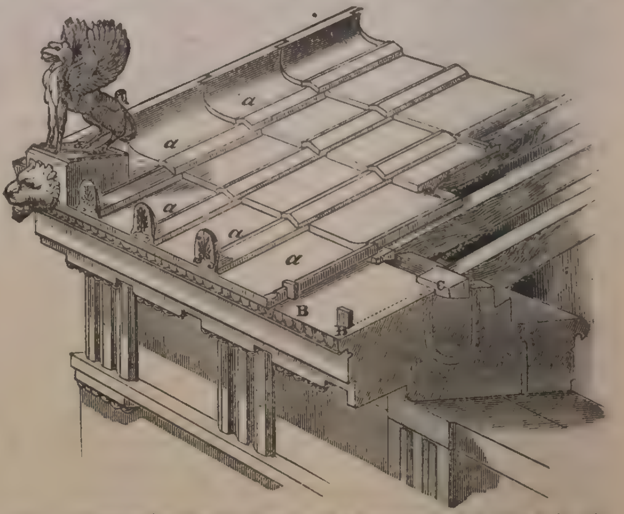


FIG. 2.—Perspective sketch showing the arrangement of tiles B in Fig. 1, at Bassæ. B, B, Dowels to fix the joint-tiles. C, tilting piece. *a*, *a*, flat surface of tiles.

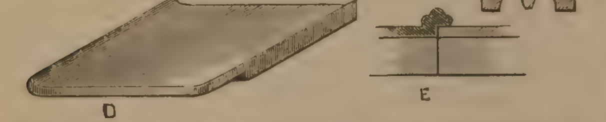

FIG. 1.—Examples of roofing tiles from Greek temples. A, B, marble tiles from Ægina and Bassæ, showing two methods of working the joint-tiles. C, C, clay tiles from Olympia. D, sketch showing method of jointing at the lower edge. E, longitudinal section of a clay joint-tile (ἁρμος). F, joint-tile with peg to fix it.

1. *Roofing Tiles.*[1]—In the most important temples of ancient Greece the roof was covered with tiles of white marble, fitted together in the most perfect way so as to exclude the rain. In most cases, as in the Athenian Parthenon and the existing temple at Ægina, the tiles were large slabs of marble, with a flange along each side, over which joint-tiles (ἁρμοί) were accurately fitted (see A in Fig. 1). In the temple of Apollo at Bassæ, though the main building was of limestone, the roof was covered with very beautiful tiles of Parian marble, which are specially mentioned by Pausanias as being one of the chief beauties of the temple. Some of these were found by Mr Cockerell during his excavations at Bassæ early in the 19th century.[2] In design they resemble the other examples mentioned above, but are peculiar in having the joint-piece worked out of the same slab of marble as the adjacent tiles (see B in Fig. 1), at a great additional cost of both material and labor, in order to secure a more perfect fit. Fig. 2 shows the way in which they were set on the roof. Great splendor of effect must have been gained by continuing the gleaming white of the columns and walls on to the roof. All along the eaves each end of a row of joint-tiles was usually covered by an *antefixa*, an oval-topped piece of marble with honeysuckle or some other conventional pattern carved in relief.[3] In most cases the Greeks used terra-cotta roofing tiles, shaped like the marble ones of Fig. 1, A. Others were without a flange, being formed with a concave upper surface to prevent the rain getting under the joint-tiles. The lower edge of the tile, whether of marble or of clay, was usually half-lapped and fitted into a corresponding rebate in the upper edge of the next tile (see D in Fig. 1). The ἁρμοί also were half-lapped at the joints (see E in Fig. 1). All these were usually fastened with bronze nails to the rafters of the roof. In some cases each joint-tile had a projecting peg to fix it to the next ἁρμός, as shown at F. In the temples of imperial Rome marble roofing tiles were used like those shown at Fig. 1. These were copied from the Greeks along with most other architectural features. For domestic and other less important work clay tiles (*tegulæ*) were employed, of the form shown in A, Fig. 3. These are narrower at the lower edge, so as to fit in to the upper edge of the next tile, and the joints were covered with a semi-circular joint-tile (*imbrex*). Rows of terra-cotta antefixæ were set along the eaves of the roof, and were often moulded with very beautiful reliefs. In localities which supplied laminated stone, such as Gloucestershire and Hampshire in Britain, the Romans often roofed their buildings with stone tiles, fastened with iron nails. Fig. 3, B, shows an example from a Roman villa at Fifehead Neville in Dorset, England. Each slab had a lap of about 2 inches over the row of tiles below it; many large iron nails were found with these stone tiles. In a few cases, in the most magnificent temples of ancient Rome, as in those of Capitoline Jupiter and of Venus and Rome, and also the small circular temple of Vesta,[4] tiles of thickly gilded bronze were used, which must have had the most magnificent effect. Those of the last-named building are specially mentioned by Pliny (*H.N.*, xxxiv. 7) as having been

---

[1] In Egypt and Assyria temples and palaces were mostly roofed with stone, while inferior buildings had flat roofs covered with beaten clay.

[2] See Cockerell, *Temples of Ægina and Bassæ*, London, 1860.

[3] Marble tiles are said to have been first made by Byzes of Naxos about 620 B.C.; see Pausanias, v. 10, 2.

[4] The dome of the Pantheon was covered with tiles or plates of bronze thickly gilt, as were also the roofs of the forum of Trajan.

made of Syracusan bronze,[1]—an alloy in great repute among the Romans. The bronze tiles from the temples of Jupiter Capitolinus and of Venus and Rome were taken by Pope Honorius I. (625–638) to cover the basilica of St. Peter, whence they were stolen by the Saracens during their invasion of the Leonine city in 846.[2]

In mediæval times lead or copper[3] in large sheets was used for the chief churches and palaces of Europe; but in more ordinary work clay tiles of very simple form were employed. One variety, still very common in Italy, is shown in C, Fig. 3. In this form of so-called "pan-tile" each tile has a double curve, forming a tegula and imbrex both in one. Stone tiles were also very common throughout the Middle Ages. Another kind of roofing tile, largely used in pre-Norman times and for some centuries later for certain purposes, was made of thin pieces of split wood, generally oak; these are called "shingles." They stand the weather fairly well, and many old examples still exist, especially on the wooden towers and spires of East Anglia. At the present day, when slate is not used, tiles of burnt clay are the ordinary roofing material, and many complicated forms have been invented to exclude rain. Most of these are, however, costly and do not answer better than a plain rectangular tile about 9 by 6 inches, fastened with two copper or even stout zinc nails, and well bedded on mortar mixed with hair. For additional security clay tiles are usually made with two small projections at the upper edge, which hook on to the battens to which they are nailed. Broseley (Shropshire) is one of the chief places in England for the manufacture of roofing tiles of the better sort. The common kinds are made wherever good clay exists. In some places pan-tiles are still used and have a very picturesque effect; but they are liable to let in the rain, as they cannot be securely nailed or well bedded in mortar. In Gloucestershire, Yorkshire, and other counties of England, stone tiles are still employed, but are rapidly going out of use, as they require very strong roof-timbers to support them, and the great extension of railways has made the common purple slates cheap in nearly every district.

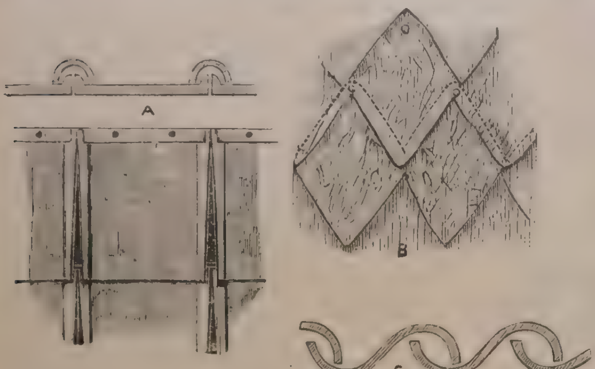

FIG. 3.—A, section and elevation of the clay tiles commonly used in ancient Rome. B, Roman stone tiles, each fixed with one iron nail at the top angle. C, pan-tiles used in mediæval and modern times.

Some of the mosques and palaces of Persia are roofed with the most magnificent enamelled lustred tiles, decorated with elaborate painting, so that they shine like gold in the sun. They were especially used from the 13th to the 15th century. In style and method of manufacture the finest of them resemble the frieze shown in Fig. 5.

2. *Wall Tiles.*—These have been partly described under MURAL DECORATION (vol. xvii. p. 42).[4] In most Oriental countries tiles were used in the most magnificent way throughout the Middle Ages, especially in Damascus, Cairo, Moorish Spain, and in the chief towns of Persia. Fig. 4 shows a fine example from a mosque in Damascus. From the 12th to the 16th century a special kind of lustred tile was largely employed for dadoes, friezes, and other wall surfaces, being frequently made in large slabs and modelled boldly in relief, with sentences from sacred books or the names and dates of reigning caliphs. The whole was picked out in color, usually dark or turquoise blue, on a ground of cream-white enamel, and in the last firing minute ornaments in copper lustre were added over the whole design, giving the utmost splendor of effect (see Fig. 5). Great skill and taste are shown by the way in which the delicate painted enrichments are made to contrast with the bold decoration in relief. These lustred tiles sometimes line the prayer-niche in houses and mosques; in such cases the slabs usually have a conventional representation of the kaaba at Mecca, with a lamp hanging in front

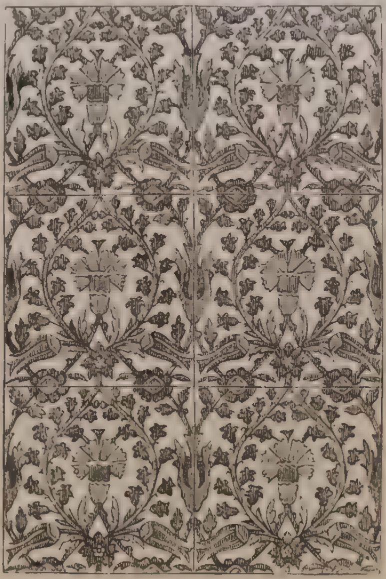

FIG. 4.—Wall tiles from Damascus, of the 16th century.

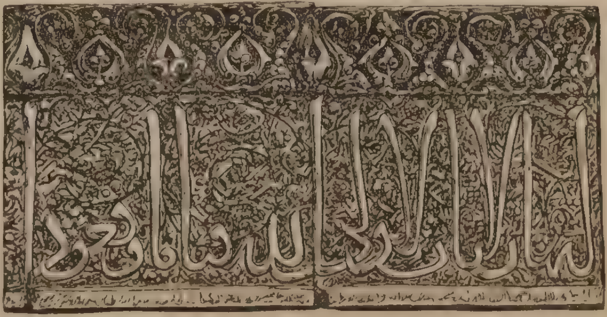

FIG. 5.—Persian lustred tiles of the 13th century, forming part of a frieze. (South Kensington Museum).

---

[1] Bronze tiles for small buildings such as this were usually of a pointed oval form, something like the feathers of a bird. This kind of tiling is called *pavonaceum* by Pliny, *H.N.*, xxxvi. 22.

[2] Part of the bronze tiles had been stripped from the temple of Jupiter by the Vandals in 455; see Procopius, *Bell. Van*., i. 5.

[3] The gilt domes of Moscow are examples of this use of copper.

[4] For the enamelled wall tiles of ancient Egypt, see POTTERY, vol. xix. p. 621.

of it and a border of sentences from the Koran.[1] The mosques of Persia are specially rich in this method of decoration, magnificent examples existing at Natenz, Seljuk, Tabríz, Ispahan, and other places.[2] In the 16th and 17th centuries tiles of a coarse kind of majolica were used for wall decoration in southern Spain; some rich examples still exist in Seville. These appear to be the work of Italian potters who had settled in Spain. The *azulejos* (wall tiles) in the Alhambra and other buildings in Spain are among the most beautiful productions of Hispano-Moorish art.[3] In technique they resemble majolica; but the finest kinds, dating from the 14th and 15th centuries, have designs taken from mosaic patterns, with complicated lines of geometrical interlacings.[4]

3. *Floor Tiles.*—From the 12th to the 16th century floor tiles in most northern countries of Europe were made by filling up with clay of a different color patterns sunk in slabs of clay (see ENCAUSTIC TILES). In Italy, during the latter part of the 15th and the first half of the 16th century, majolica tiles, rich both in pattern and in color, were used for pavements in many places. Comparatively few examples now exist; the majolica enamel was too soft to stand the wear of feet. One of the small south chapels in the church of S. Maria del Popolo in Rome has a very fine pavement of these tiles, executed, probably at Forlì, about 1480 for Cardinal della Rovere (Julius II.), whose arms—an oak tree—are repeated frequently among the rich decorations. A still more magnificent tile floor in the uppermost of Raphael's Vatican loggie is mentioned under ROBBIA (vol. xx. p. 607). The same article (p. 605) describes the exquisite majolica tiles which Luca della Robbia made as a border for the tomb of Bishop Federighi at Florence. Fine examples of tile paving of 1487 exist in the basilica of S. Petronio at Bologna, and others of rather earlier date in S. Paolo at Parma. The chapel of St. Catherine at Siena and the church of S. Sebastiano at Venice have majolica paving of about 1510. Fig. 6 shows an example of about this date from the Petrucci Palace in Siena, now in the South Kensington Museum.[5] In the early part of the 16th century majolica tiles from Spain were occasionally imported into England. At the southeast of the mayor's chapel at Bristol there exists, though much worn, a fine pavement of Spanish tiles dating from about 1520. Others have been found in London, at Newington Butts, and in other places. At the present time imitations of the unfortunately named "encaustic tiles" are almost the only sort employed in England and other northern countries. Very coarse and poorly designed majolica tiles are still made and used for paving in Italy and Spain.

(J. H. M.)

TILLEMONT, SÉBASTIEN LE NAIN DE (1637–1698), ecclesiastical historian, was born at Paris on 30th November, 1637 and received his education in the "petites écoles" of the Port Royalists, Nicole being his principal master. At an early age he became an admiring student of Livy and Baronius and began to accumulate those vast collections which form the basis of his monumental works. He continued to carry on his studies in the seminary at Beauvais, where the bishop was a warm patron; but it was not until 1676, two or three years after his return to Paris, that, under the influence of Isaac de Sacy, he entered the priesthood. He took up his abode in a humble dwelling at Port Royal des Champs, where he remained till the dispersion of the "solitaires" in 1679, after which event he spent the remainder of his life (with the exception of a visit to Arnauld in Holland in 1685) at Tillemont, between Montreuil and Vincennes. He died on 28th January, 1698, and was buried at Port Royal; in 1711 his remains were removed to the church of St. André des Arcs, Paris.

His great work, *Mémoires pour servir à l' histoire ecclésiastique des six premiers siècles* to 513 A.D. (1693–1712, 16 vols., 4to), is a model of patient, exhaustive, and what Gibbon has called "sure-footed" erudition (see vol. v. p. 669). Of his equally learned *Histoire des empereurs et des autres princes qui ont régné durant les six premiers siècles de l' église* (1690–1738, 4to) no more than four volumes were published. Tillemont also gave valuable assistance to Hermant, Du Fossé, and other Port Royalists in their historical work.

TILLOTSON, JOHN (1630–1694), archbishop of Canterbury, was the son of a Puritan clothier in Sowerby, Yorkshire, where he was born in October, 1630. He entered as a pensioner of Clare Hall, Cambridge, in 1647, graduated in 1650, and was made fellow of his college in 1651. Chillingworth's *Religion of Protestantism* biassed his mind against Puritanism, and the bias was further confirmed by intercourse with Cudworth and others at Cambridge. In 1656 he became tutor to the son of Edward Prideaux, attorney-general to Cromwell. In what year he took orders is unknown, but, according to the *Life* published in 1717, the person who ordained him was Dr. T. Sydserf, a Scottish bishop. Tillotson was present at the Savoy Conference in 1661, and remained identified with the Presbyterians till the passing of the Act of Uniformity in 1662. Shortly afterwards he became curate of Cheshunt, Herts, and in June, 1663, rector of Keddington, Suffolk. For several years after his ordination he devoted himself to an exact study of the Scriptures, ancient ethics, and the writings of the early fathers, especially Basil and Chrysostom. The result was seen in the general tone of his preaching, which was practical rather than theological, and, though regarded by some as latitudinarian, was characterized by the earnestness of sincere conviction and the balanced wisdom gained by thoughtful reflection. He was, moreover, a man of the world as well as a divine, and in his sermons he exhibited a certain indefinable tact which enabled him at once to win the ear of his audience. His style is chiefly remarkable for its simplicity and clearness, and in this respect it mirrored his own candor and sincerity. The qualities above mentioned won him in his lifetime the reputation of "having brought preaching to perfection;" and probably it was because he was neither brilliant, original, nor profound that his preaching was so universally admired. "His sermons," says Burnet, "were so well heard and liked, and so much read, that all the nation proposed him as a pattern and studied to copy after him." In 1664 he became preacher at Lincoln's Inn. The same year he married Miss French, daughter of the canon of Christ Church, Oxford, and niece of Oliver Cromwell; and he also became Tuesday lecturer at St. Lawrence, Jewry. Tillotson employed his controversial weapons with some skill against "atheism" and "Popery." In 1663 he published a characteristic sermon on "The Wisdom of being Religious," and in 1666 replied to Sergeant's *Sure Footing in Christianity* by a pamphlet on the *Rule of Faith.* The same year he received the degree of D.D. In 1670 he became prebendary and in 1672 dean of Canterbury. Through his wife Tillotson became connected with Dr. Wilkins, the second husband of her mother. In 1675 he edited Wilkins's *Principles of Natural Religion*, completing what was left unfinished of it, and in 1682 his *Sermons*, with a preface in which he vindicated Wilkins from certain misrepresentations of Wood in his *History and Antiquities of the University of Oxford.* In 1680 he brought out Barrow's *Treatise of the Pope's Supremacy*, and in 1683 his *Sermons.* On 5th November, 1678, Tillotson preached a sermon against Popery before the House of Commons, in which he maintained that it was their duty to make provision against the propagation of a religion more mischievous than irreligion itself; but in a sermon on the Protestant religion in 1680 before the king he propounded the proposition that Catholics could enjoy their own faith, but not openly draw men off from the profession of the established religion. Along with Burnet, Tillotson attended Lord Russell on the scaffold in 1683, and after the publication of Lord Russell's speech was appointed to appear before the privy council; but his explanations were regarded as satisfactory, the chief suspicions in connection with the speech resting on Burnet. Tillotson afterwards enjoyed the friendship of Lady Russell, and it was partly through her that he obtained so much influence with Princess Anne, who followed his advice in regard to the settlement of the crown on William of Orange. He possessed the special confidence of William and Mary, and was made clerk of the closet to the king, 27th March, 1689. It was chiefly through his advice that the king appointed an ecclesiastical commission for the reconciliation of the Dissenters, and he was regarded as the representative in the commission of the views of the king and queen. In August of this year he was appointed by the chapter of his cathedral to exercise the archiepiscopal jurisdiction of the province of Canterbury during the suspension of Sancroft. He was also about the same time named dean of St. Paul's. Soon afterwards he was elected to succeed Sancroft; but he accepted the promotion with extreme reluctance, and it was deferred from time to time at his request till April, 1691. His attempts to reform certain abuses of the church, especially that of nonresidence among the clergy, awakened against him much ill-will, and of this the Jacobites took every possible advantage and pursued him to the end of his life with insult and reproach. "This" Burnet says, "could neither provoke him, nor fright him from his duty; but it affected his mind so much that this was thought to have shortened his days." He died of palsy on 24th November, 1694.

---

[1] The South Kensington Museum, London, contains many fine examples, as well as of the later sorts, like those shown in Fig. 4.

[2] See Coste, *Monuments de la Perse*, Paris, 1867.

[3] The method of manufacture employed by Moslem races for tiles is the same as that used for their pottery; see vol. xix. pp. 638–42, also MURAL DECORATION, vol. xvii. pp. 41–42.

[4] For the decorative use of tiles, see Julien Foy, *La Céramique des Constructions*, Paris, 1883.

[5] See Vanzolini, *Fabbriche di Maioliche*, Pesaro, 1879, ii. p. 229 *sq.*; and Frati, *Pavimento nella Bas Petroniana*, Bologna, 1853.

For his manuscript sermons Tillotson's widow received 2500 guineas [$12,757,50], then an unexampled sum, and for many years their popularity remained unrivalled. During his lifetime he published *Sermons on Several Occasions*, 1671, republished with a second volume added in 1678; *Fifty Sermons and the Rule of Faith*, 1691; *Four Sermons concerning the Divinity and Incarnation of our Blessed Saviour*, 1693; *Six Sermons on Several Occasions*, 1694. His *Posthumous Sermons*, edited by Dr. Ralph Barker, appeared in 14 vols., 1694; third edition, 1704. His *Works* were published in 1707–1710, and were frequently reprinted. In 1752 an edition appeared in 3 vols. with *Life* by Thomas Birch, D.D., compiled from Tillotson's original papers and letters. Of the many subsequent editions the best is that with *Life* by Birch, of 1820, 10 vols. Various selections from his sermons and works have been published separately.

See in addition to Birch's *Life*, Welford's *Memorials*, Burnet's *Own Times*, and Macaulay's *History of England.*

TILLY, JOHANN TSERCLAES, COUNT OF (1559–1632), a famous general, was born in February, 1559, at the chateau of Tilly in Brabant. It was originally intended that he should become a priest, and he was strictly educated by the Jesuits. He preferred, however, the life of a soldier, and began his military career in the Netherlands, under Alessandro Farnese, in the Spanish service. Afterwards he joined the imperial army, and as lieutenant-colonel under Duke Philip Emmanuel of Lorraine greatly distinguished himself in Hungary in the war against the Turks. For his brilliant achievements he was raised to the rank of field-marshal. In 1610 he was put by Maximilian I. at the head of his Bavarian army; and soon after the outbreak of the Thirty Years' War he was made commander-in-chief of the troops of the Catholic League. In this position he displayed qualities which placed him among the foremost generals of the age. After the battle of Prague (the White Hill) in 1620 he thoroughly subdued Bohemia, and in 1622 conquered the Palatinate,—a service for which Ferdinand II. gave him the title of count. In 1623 he defeated Christian of Brunswick at Stadtlohn in Westphalia, and in 1626 Christian IV. of Denmark at Lutter in Brunswick. The consequence of the latter victory was that Tilly and Wallenstein were able to cross the Elbe; but as Tilly was wounded before Pinneberg in Schleswig-Holstein, the task of finally compelling the king of Denmark to accept terms of peace had to be left to Wallenstein alone. When Wallenstein was obliged in 1630 to withdraw for a while into private life, Tilly added to the functions he already discharged those of commander of the imperial forces. From this time the only important success achieved by him was the storming of Magdeburg (May, 1631), a success accompanied by frightful cruelties, for which he was at least in part responsible. Gustavus Adolphus had now come forward as the champion of Protestantism, and Tilly, with all his genius and tenacity, was not a match for the Swedish king. Four months after the capture of Magdeburg Tilly was defeated at Breitenfeld in Saxony, and was himself so severely wounded that he escaped from the field with difficulty. In March, 1632, he drove the Swedes from Bamberg and placed himself in an entrenched camp at Rain to prevent them from passing over the Lech. Gustavus Adolphus crossed the stream, and in the fight which ensued Tilly was mortally wounded. He died in April, 1632, at Ingolstadt, and was buried at Alt-Oetting in Bavaria.

Tilly was of medium height, reserved in manner, and wholly indifferent to external marks of honor. The Roman Church never had a more devoted servant, and he gave evidence of the essential simplicity of his character by declining the offer of the emperor to make him a prince and to grant to him the principality of Calenberg. As he was not married, his title and estates descended to his nephew.

See Klopp, *Tilly im dreissigjährigen Kriege*, Stuttgart, 1861, and Villermont, *Tilly*, Tournay, 1859.

TILSIT, a commercial town of East Prussia and the capital of Prussian Lithuania, is situated on the left bank of the Memel or Niemen, 52 miles southeast of the town of Memel and 60 northeast of Königsberg. The town is spacious, and has a number of handsome modern buildings, including a town-house, post-office, law-courts, and a large hospital. It contains three Protestant churches, a Roman Catholic church, and a Jewish synagogue. The manufactures include soap, leather, shoes, glass, and other articles, and there are iron-foundries and steam flour and saw mills. Tilsit carries on trade in timber, grain, hemp, flax, herrings, and other northern produce; but its trade with Russia, at one time considerable, has fallen off since the construction of the railway from Königsberg *via* Insterburg and Gumbinnen to Kovno. The river is navigable beyond the town. The market-gardening of the neighborhood deserves mention, and the annual horse-fair and markets are of considerable local importance. In 1783 the population was 8060; in 1880 it had increased to 21,400, and in 1885 to 22,428.

Tilsit, which received town-rights in 1552, grew up around a castle of the Teutonic order, known as the "Schalauner Haus," founded in 1288. It owes most of its interest to the peace signed here on 9th July, 1807, the preliminaries of which were settled by the emperors Alexander and Napoleon on a raft moored in the Memel. The peace of Tilsit, which constituted the kingdom of Westphalia and the duchy of Warsaw, registers the nadir of Prussia's humiliation under Napoleon (see Prussia, vol. xx. p. 15). The poet Max von Schenkendorf (1784–1817) was born at Tilsit.

TIMBER. See Building, Forests, and Strength of Materials; also Fir, Oak, Pine, Teak, etc.

TIMBUKTU, or Timbuctoo (Sonrhai, *Timbutu;* Berber, *Tumbutku;* Arab, *Tin-buktu*), a city of the Sahara, on the southern verge of the desert, in 18° 4′ N. lat. and 1° 45′ W. long., at the northeast extremity of the Fulah state of Moassina (Massina), 9 miles north of its riverine port Kabara, on the left bank of the Niger, at the confluence of the numerous branches of the Joliba (upper Niger) where it trends eastwards, and at the converging point of the main trade routes from the Gulf of Guinea and from the Mediterranean across the western Sahara. Timbuktu lies on a terrace formed by the southern scarp of the desert, about 800 feet above sea-level, and overlooking a chain of *dhayas* or marshy hollows, fringed here and there with a few mimosas and palm thickets, amid the surrounding sandy wastes. These dhayas, which are flooded every three or four years, converting the lowland tracts between the terrace and the main stream into a labyrinth of channels and back waters, mark the bed of a navigable creek which formerly branched from the Niger northwards to the foot of the scarp, and which in 1640 inundated a low-lying quarter of the city. According to Pouyanne and Sabatier, the main stream followed this course before it took its present easterly curve to Burum, where it bends southwards to the coast. Here also it was probably joined at some remote period by the now dried-up Wady Messaura from the Tuát oases south of Algeria, although the rough levels taken by Oscar Lenz and others make it uncertain whether the flow through this depression was northwards or southwards. In any case Timbuktu has been left, so to say, high and dry by the general process of desiccation going on throughout the Saharian region. It was founded, or more probably captured, by the Tuareg Berbers about the 11th century, and under the Mandingo kings of Mali (Mallé) was a noted mart for gold and salt in the 14th century, mention of "Timboutch" occurring on a Catalan map dated 1373. Under Askia, founder of the extensive but short-lived Sonrhai empire (1492), it rose to great splendor and became with Gogo a chief centre of Mohammedan culture for the peoples of western Sudan. But since the overthrow (1591) of the Sonrhai dynasty by the Morocco captain, the Andalusian Jodar with his Ruma followers, Timbuktu has continued to be the prey of the surrounding unruly populations—Tuaregs, Arabs or Arabized Berbers, Fulahs (1800), and Toucouleurs (1865). Being thus at the mercy of all, it has ceased to rebuild its dismantled walls, being content to pay tribute to each in turn and sometimes to more than one simultaneously, for which it indemnifies itself by peaceful intervals of trade whenever the land routes are open and the upper and lower reaches of the Niger are clear of pirates. But at times even the short tract separating it from Kabara is so beset with marauders that it bears the ominous name of "Ur-immandess," that is, "He (God) hears not." Recently, however, it has enjoyed a considerable interval of peace, and the population estimated by Barth at 11,000 in 1853, had risen to 20,000 in 1880 (Lenz). These form a motley group of Sonrhais, Tuaregs, Mandingoes, Arabs from Morocco, Berabish Arabs, Bambaras, Fulahs, and since 1850 a few Jewish traders. Apart from some Christian captives, the place was reached during the 19th century by only four Europeans—Laing from Tripolitana (1826) who was murdered on his return journey, Caillié from the north (1828), Barth from central Sudan (1853), and Lenz from Morocco (1880). Since 1884, however, regular relations have been opened with the French on the upper Niger.

From the ruins covering extensive tracts on the north and west sides, it is evident that Timbuktu was formerly a much larger place than at present. Even the great mosque, which must at one time have stood in the centre, now lies near the outskirts, where its high but unsightly earth tower forms a striking landmark. The aggregate of mean hovels or mud houses of which the place consists is only relieved by a few structures of a better class. As in former times, a great staple of trade is salt from Taudeni and other parts of the Sahara, here exchanged with gold dust for kola nuts from the south, Manchester goods, and some other European wares, which with tea are imported from Morocco or penetrate from the British protected territories along the lower Niger. Cowries, slowly yielding to European moneys, are the chief currency. The local industries are mainly confined to some fancy and other leatherwork prepared by the Tuareg women. The local administration is in the hands of an hereditary *kahia*, a kind of mayor, descended from one of the Ruma families. The kahia is himself more or less under the control of a neighboring Tuareg chief and of the powerful Bakhai family, who, as "sherífs" and marabouts, are revered throughout the western Sahara. Timbuktu, which possesses some valuable Arabic manuscripts and is still a centre of Moslem teaching, is a converging point of the chief west Sudanese and Saharan races—Arabs or Arabized Berbers to the west; Sonrhais in the immediate vicinity, and thence southeastwards along the Niger; Ireghenaten or "mixed" Tuaregs southwards across the Niger as far as the Hombori Hills and in the fertile Libbako plains beyond them; Fulahs, Mandingoes, and Bambaras in and about the city; and Imóhag or Imósharh Tuaregs belonging to the Awellimiden confederation mainly to the north and east.

TIME, Measurement of. Time is measured by successive phenomena recurring at regular intervals. The only astronomical phenomenon which rigorously fulfils this condition, and the most striking one,—the apparent daily revolution of the celestial sphere caused by the rotation of the earth,—has from the remotest antiquity been employed as a measure of time. The interval between two successive returns of a fixed point on the sphere to the meridian is called the sidereal day; and sidereal time is reckoned from the moment when the "first point of Aries" (the vernal equinox) passes the meridian, the hours being counted from 0 to 24. Clocks and chronometers regulated to sidereal time are only used by astronomers, to whom they are indispensable, as the sidereal time at any moment is equal to the right ascension of any star just then passing the meridian. For ordinary purposes solar time is used. In the article Astronomy (vol. ii. pp. 674–675) it is shown that the solar day, as defined by the successive returns of the sun to the meridian, does not furnish a uniform measure of time, owing to the slightly variable velocity of the sun's motion, and the inclination of its orbit to the equator, so that it becomes necessary to introduce an imaginary mean sun moving in the equator with uniform velocity. The equation of time (*loc. cit.*, pp. 675) is the difference between apparent (or true) solar time and mean solar time. The latter is that shown by clocks and watches used for ordinary purposes. Mean time is converted into apparent time by applying the equation of time with its proper sign, as given in the *Nautical Almanac* and other ephemerides for every day at noon. As the equation varies from day to day, it is necessary to take this into account, if the apparent time is required for any moment different from noon. The ephemerides also give the sidereal time at mean noon, from which it is easy to find the sidereal time at any moment, as 24 hours of mean solar time are equal to $24^h\ 3^m\ 56.5554^s$ of sidereal time. About 21st March of each year a sidereal clock agrees with a mean-time clock, but it gains on the latter $3^m\ 56.5^s$ every day, so that in the course of a year it has gained a whole day. For a place not on the meridian of Greenwich the sidereal time at noon must be corrected by the addition or subtraction of 9.8565^s for each hour of longitude, according as the place is west or east of Greenwich.

While it has for obvious reasons become customary in all civilized countries to commence the ordinary or civil day at midnight, astronomers count the day from noon, being the transit of the mean sun across the meridian, in strict conformity with the rule as to the beginning of the sidereal day. The hours of the astronomical day are also counted from 0 to 24. An international conference which met in the autumn of 1884 at Washington, to consider the question of introducing a universal day (see below), has recommended that the astronomical day should commence at midnight, to make it coincide with the civil day. The great majority of American and Continental astronomers have, however, expressed themselves very strongly against this change; and even if it should be made in the *British Nautical Almanac*, it appears very doubtful whether the other great ephemerides will adopt it, the more so as astronomers have hitherto felt no inconvenience from the difference between the astronomical and the civil day.

Determination of Time.—The problem of determining the exact time at any moment is practically identical with that of determining the apparent position of any known point on the celestial sphere with regard to one of the fixed (imaginary) great circles appertaining to the observer's station, the meridian or the horizon. The point selected is either the sun or one of the standard stars, the places of which are accurately determined and given for every tenth day in the modern ephemerides. The time thus determined furnishes the *error* of the clock chronometer, or watch employed, and a second determination of time after an interval gives a new value of the error and thereby the *rate* of the timekeeper.

The ancient astronomers, although they have left us very ample information about their dials, water or sand clocks (*clepsydræ*), and similar timekeepers, are very reticent as to how these were controlled. Ptolemy, in his *Almagest*, states nothing whatever as to how the time was found when the numerous astronomical phenomena which he records took place; but Hipparchus in the only book we possess from his hand gives a list of forty-four stars scattered over the sky at intervals of right ascension equal to exactly one hour, so that one or more of them would be on the meridian at the commencement of every sidereal hour. In a very valuable paper[1] Schjellerup has shown that the right ascensions assumed by Hipparchus agree within about 15′ or one minute of time with those calculated back to the year 140 B.C. from modern star-places and proper motions. The accuracy which, it thus appears, could be attained by the ancients in their determinations of time was far beyond what they seem to have considered necessary, as they only record astronomical phenomena (*e.g.*, eclipses, occultations) as having occurred "towards the middle of the third hour," or "about 8½ hours of the night," without ever giving minutes.[2] The Arabians had a clearer perception of the importance of knowing the accurate time of phenomena, and in the year 829 we find it stated that at the commencement of the solar eclipse on 30th November the altitude of the sun was 7° and at the end 24°, as observed at Baghdad by Ahmed ibn Abdallah, called Habash.[3] This seems to be the earliest determination of time by an altitude; and this method then came into general use among the Arabians, who on observing lunar eclipses never failed to measure the altitude of some bright star at the beginning and end of the eclipse. In Europe this method was adopted by Purbach and Regiomontanus, apparently for the first time in 1457. Bernhard Walther, a pupil of the latter, seems to have been the first to use for scientific purposes clocks driven by weights: he states that on 16th January, 1484, he observed the rising of the planet Mercury and immediately attached the weight to a clock having an hour-wheel with fifty-six teeth; at sunrise one hour and thirty-five teeth had passed, so that the interval was an hour and thirty-seven minutes. For nearly two hundred years, until the application of the pendulum to clocks became general, astronomers could place little or no reliance on their clocks, and consequently it was always necessary to fix the moment of an observation by a simultaneous time determination. For this purpose Tycho Brahe employed altitudes observed with quadrants; but he remarks that they are not always of value, for if the star is taken too near the meridian the altitude varies too slowly, and if too near the horizon the refraction (which at that time was very imperfectly known) introduces an element of uncertainty. He therefore preferred azimuths, or with the large "armillary spheres" which played so important a part among his instruments he measured hour-angles or distances from the meridian along the equator.[4] Transits of stars across the meridian were also observed with the meridian quadrant, an instrument which is alluded to by Ptolemy and was certainly in use at the Marágha (Persia) observatory in the 13th century, but of which Tycho was the first to make extensive use. It appears, however, that he chiefly employed it for determining star-places, having obtained the clock error by the methods already described.

In addition to these methods, that of "equal altitudes" was much in use during the 17th century. That equal distances east and west of the meridian correspond to equal altitudes had of course been known as long as sun-dials had been used; but, now that quadrants, cross-staves, and parallactic rules[5] were commonly employed for measuring altitudes more accurately, the idea naturally suggested itself to determine the time of a star's or the sun's meridian passage by noting the moments when it reached any particular altitude on both sides of the meridian. But Tycho's plan of an instrument fixed in the meridian was not forgotten, and from the end of the 17th century, when Roemer invented the transit instrument, the observation of transits across the meridian became the principal means of determining time at fixed observatories, while the observation of altitudes, first by portable quadrants, afterwards by reflecting sextants, and during the 19th century by portable alt-azimuths or theodolites, has been used on journeys. During the last fifty years the small transit instrument, with what is known as a "broken telescope," has also been much employed on scientific expeditions; but great caution is necessary in using it, as the difficulties of getting a perfectly rigid mounting for the prism or mirror which reflects the rays from the object-glass through the axis to the eye-piece appear to be very great, for strange discrepancies in the results have often been noticed. The gradual development of astronomical instruments has been accompanied by a corresponding development in timekeepers. From being very untrustworthy, astronomical clocks are now made to great perfection by the application of the pendulum and by its compensation, while the invention of chronometers has placed a portable and equally trustworthy timekeeper in the hands of travellers.

We shall now give a sketch of the principal methods of determining time.

In the spherical triangle ZPS between the zenith, the pole, and a star the side $ZP = 90° - \phi$ (ϕ being the latitude), $PS = 90° - \delta$ (δ being the declination), and ZS or $Z = 90°$ minus the observed altitude. The angle $ZPS = t$ is the star's hour-angle or, in time, the interval between the moment of observation and the meridian passage of the star. We have then

$$\cos t = \frac{\cos Z - \sin\phi \sin\delta}{\cos\phi \cos\delta},$$

which formula can be made more convenient for the use of logarithms by putting $Z + \phi + \delta = 2S$, which gives

$$\tan^2 \tfrac{1}{2}t = \frac{\sin(S-\phi)\sin(S-\delta)}{\cos S \cos(S-Z)}.$$

According as the star was observed west or east of the meridian, t will be positive or negative. If a be the right ascension of the star, the sidereal time $= t + a$, a as well as δ being taken from an ephemeris. If the sun had been observed, the hour-angle t would be the apparent solar time. The altitude observed must be corrected for refraction, and in the case of the sun also for parallax, while the sun's semi-diameter must be added or subtracted, according as the lower or upper limb was observed. The declination of the sun being variable, and being given in the ephemerides for noon of each day, allowance must be made for this by interpolating with an approximate value of the time. As the altitude changes very slowly near the meridian, this method is most advantageous if the star be taken near the prime vertical, while it is also easy to see that the greater the latitude the more uncertain the result. If a number of altitudes of the same object are observed, it is not necessary to deduce the clock error separately from each observation, but a correction may be applied to the mean of the zenith distances. Supposing n observations to be taken at the moments $T_1, T_2, T_3, \ldots$, the mean of all being T_0, and calling the z corresponding to this Z, we have

$$z_1 = Z + \frac{dZ}{dt}(T_1 - T_0) + \frac{1}{2}\frac{d^2Z}{dt^2}(T_1 - T_0)^2;$$
$$z_2 = Z + \frac{dZ}{dt}(T_2 - T_0) + \frac{1}{2}\frac{d^2Z}{dt^2}(T_2 - T_0)^2;$$

and so on, t being the hour-angle answering to T_0. As $\Sigma(T - T_0) = 0$, these equations give

$$Z = \frac{z_1 + z_2 + z_3 + \ldots}{n} - \frac{1}{2}\frac{d^2Z}{dt^2}\frac{(T_1 - T_0)^2 + (T_2 - T_0)^2 + \ldots}{n};$$
$$= \frac{z_1 + z_2 + z_3 + \ldots}{n} - \frac{d^2Z}{dt^2}\frac{\Sigma 2\sin^2\frac{1}{2}(T - T_0)}{n}.$$

But, if in the above-mentioned triangle we designate the angles at Z and S by $180° - A$ and p, we have

$$\sin z \sin A = \cos\delta \sin t;$$
$$\sin z \cos A = -\cos\phi \sin\delta + \sin\phi \cos\delta \cos t;$$

and by differentiation

$$\frac{d^2Z}{dt^2} = \frac{\cos\phi \cos\delta \cos A \cos p}{\sin Z},$$

in which A and p are determined by

$$\sin A = \frac{\sin t}{\sin Z}\cos\delta \text{ and } \sin p = \frac{\sin t}{\sin Z}\cos\phi.$$

With this corrected mean of the observed zenith distances the hour-angle and time are determined, and by comparison with T_0 the error of the timekeeper.

The method of equal altitudes gives very simply the clock error equal to the right ascension minus half the sum of the clock times corresponding to the observed equal altitudes on both sides of the meridian. When the sun is observed, a correction has to be applied for the change of declination in the interval between the observations. Calling this interval $2t$, the correction to the apparent noon given by the observations x, the change of declination in half the interval $\Delta\delta$, and the observed altitude h, we have

$$\sin h = \sin\phi \sin(\delta - \Delta\delta) + \cos\phi \cos(\delta - \Delta\delta)\cos(t + x)$$
$$\text{and } \sin h = \sin\phi \sin(\delta + \Delta\delta) + \cos\phi \cos(\delta + \Delta\delta)\cos(t - x),$$

whence, as $\cos x$ may be put $= 1$, $\sin x = x$, and $\tan\Delta\delta \doteq \delta\Delta$,

$$x = -\left(\frac{\tan\phi}{\sin t} - \frac{\tan\delta}{\tan t}\right)\Delta\delta,$$

which, divided by 15, gives the required correction in seconds of time. Similarly an afternoon observation may be combined with an observation made the following morning to find the time of apparent midnight.

The observation of the time when a star has a certain azimuth may also be used for determining the clock error, as the hour-angle can be found from the declination, the latitude, and the azimuth. As the azimuth changes most rapidly at the meridian, the observation is most advantageous there, besides which it is neither necessary to know the latitude nor the declination accurately. In the article GEODESY (vol. x. p. 149) it has been shown how the observed time of transit over the meridian is corrected for the deviations of the instrument in azimuth, level, and collimation. This corrected time of transit, expressed in sidereal time, should then be equal to the right ascension of the object observed, and the difference is the clock error. In observatories the determination of a clock's error (a necessary operation during a night's work with a transit circle) is generally founded on observations of four or five "clock stars," these being standard stars not near the pole, of which the absolute right ascensions have been determined with great care, besides observation of a close circumpolar star for finding the error of azimuth and determination of level and collimation error.[1]

Observers in the field with portable instruments often find it inconvenient to wait for the meridian transits of one of the few close circumpolar stars given in the ephemerides. In that case they have recourse to what is known as the method of time determination in the vertical of a pole star. The alt-azimuth is first directed to one of the standard stars near the pole, such as a or δ Ursæ Minoris, using whichever is nearest to the meridian at the time. The instrument is set so that the star in a few minutes will cross the middle vertical wire in the field. The spirit-level is in the meantime put on the axis and the inclination of the latter measured. The time of the transit of the star is then observed, after which the instrument, remaining clamped in azimuth, is turned to a clock star and the transit of this over all the wires is observed. The level is applied again, and the mean of the two results is used in the reductions. In case the collimation error of the instrument is not accurately known, the instrument should be reversed and another observation of the same kind taken. The observations made in each position of the instrument are separately reduced with an assumed approximate value of the error of collimation, and two equations are thus derived from which the clock error and correction to the assumed collimation error are found. This use of the transit or alt-azimuth out of the meridian throws considerably more work on the computer than the meridian observations do, and it is therefore never resorted to except when an observer during field operations is pressed for time. The formulæ of reduction as developed by Hansen in the *Astronomische Nachrichten* (vol. xlviii. p. 113 *sq.*) are given by Chauvenet in his *Spherical and Practical Astronomy* (vol. ii. p. 216 *sq.*, 4th ed., Philadelphia, 1873). The subject has also been treated at great length by Döllen in two memoirs, *Die Zeitbestimmung vermittelst des tragbaren Durchgangs-instrument im Verticale des Polarsterns* (St. Petersburg, 1863 and 1874, 4to).

Longitude.—Hitherto we have only spoken of the determination of local time. But in order to compare observations made at different places on the surface of the earth a knowledge of their difference of longitude becomes necessary, as the local time varies proportionally with the longitude, one hour corresponding to 15°. Longitude can be determined either geodetically or astronomically. The first method supposes the earth to be a spheroid of known dimensions. Starting from a point of departure of which the latitude has been determined, the azimuth from the meridian (as determined astronomically) and the distance of some other station are measured. This second station then serves as a point of departure to a third, and by repeating this process the longitude and latitude of places at a considerable distance from the original starting-point may be found. Referring for this method to the articles EARTH (FIGURE OF THE), GEODESY, and SURVEYING, we shall here only deal with astronomical methods of determining longitude.

---

[1] The probable error of a clock correction found in this way from one star with the Dunsink transit circle was $\pm 0.052^s$.

The earliest astronomer who determined longitude by astronomical observations seems to have been Hipparchus, who chose for a first meridian that of Rhodes, where he observed; but Ptolemy adopted a meridian laid through the "Insulæ Fortunatæ" as being the farthest known place towards the west.[1] When the voyages of discovery began the peak of Teneriffe was frequently used as a first meridian, until a scientific congress, assembled by Richelieu at Paris in 1630, selected the island of Ferro for this purpose. Although various other meridians (*e.g.*, that of Uranienburg and that of San Miguel, one of the Azores, 29° 25′ west of Paris) continued to be used for a long time, that of Ferro, which received the authorization of Louis XIII. on 25th April, 1634, gradually superseded the others. In 1724 the longitude of Paris from the west coast of Ferro was found by Louis Feuillée, who had been sent there by the Paris Academy, to be 20° 1′ 45″; but on the proposal of Guillaume de Lisle (1675–1726) the meridian of Ferro was assumed to be exactly 20° west of the Paris observatory. Modern maps and charts generally give the longitude from the observatory of either Paris or Greenwich according to the nationality of the constructor; the Washington meridian conference of 1884 has recommended the exclusive use of the meridian of Greenwich. On the same occasion it was also recommended to introduce the use of a "universal day," beginning for the whole earth at Greenwich midnight, without, however, interfering with the use of local time.[2]

The simplest method for determining difference of longitude consists in observing at the two stations some celestial phenomenon which occurs at the same absolute moment for the whole earth. Hipparchus pointed out how observations of lunar eclipses could be used in this way, and for about fifteen hundred years this was the only method available. When REGIOMONTANUS (*q.v.*) began to publish his ephemerides towards the end of the 15th century, they furnished other means of determining the longitude. Thus Amerigo Vespucci observed on 23d August, 1499, somewhere on the coast of Venezuela, that the moon at $7^h\,30^m$ P.M. was 1°, at midnight 5½° east of Mars; from this he concluded that they must have been in conjunction at $6^h\,30^m$, whereas the Nuremberg ephemeris announced this to take place at midnight. This gave the longitude of his station as roughly equal to 5½ hours west of Nuremberg. The instruments and the lunar tables at that time being very imperfect, the longitudes determined were very erroneous; see NAVIGATION (vol. xvii. p. 275), to which article we may also refer for a history of the long-discussed problem of finding the longitude at sea. The invention of the telescope early in the 17th century made it possible to observe eclipses of Jupiter's satellites; but there is to a great extent the same drawback attached to these as to lunar eclipses, that it is impossible to observe with sufficient accuracy the moments at which they occur.

Eclipses of the sun and occultations of stars by the moon were also much used for determining longitude before the invention of chronometers and the electric telegraph offered better means for fixing the longitude of observatories. These methods are now hardly ever employed except by travellers, as they are very inferior as regards accuracy. For the necessary formulæ see Chauvenet's *Spherical and Practical Astronomy*, vol. i. pp. 518–542 and 550–557.

We now proceed to consider the four methods for finding the longitudes of fixed observatories, viz., by (1) moon culminations, (2) rockets or other signals, (3) transport of chronometers, and (4) transmission of time by the electric telegraph.

1. *Moon Culminations.*—Owing to the rapid orbital motion of the moon the sidereal time of its culmination is different for different meridians. If, therefore, the rate of the moon's change of right ascension is known, it is easy from the observed time of culmination at two stations to deduce their difference of longitude. Let the right ascension of the moon a and its differential coefficients be computed for the Greenwich time T, and let the culmination be observed at two places whose longitudes from Greenwich are λ and λ', the time of observation being $T+t$ and $T+t'$ Greenwich time, or in local time $T+t+\lambda=\theta$ and $T+t'+\lambda'=\theta'$; we have then

$$\theta'-\theta=(t'-t)\frac{da}{dt}+\frac{1}{2}(t'^2-t^2)\frac{d^2a}{dt^2}+\ldots,$$

and, as the difference of longitude is $\lambda'-\lambda=(\theta'-\theta)-(t'-t)$, we have only to determine $t'-t$ from the first equation. This is simply done by a suitable selection of T. Calling $T+\frac{1}{2}(t+t')=T'$, we have to put $T'-\frac{1}{2}(t'-t)$ and $T'+\frac{1}{2}(t'-t)$ for $T+t$ and $T+t'$. It is then easy to see that

$$\theta'-\theta=(t'-t)\frac{da}{dt}+\frac{1}{24}(t'-t)^3\frac{d^3a}{dt^3},$$

and, solving this equation by first neglecting the second term on the right side and then substituting the value of $t'-t$, thus found in that term, $t'-t=\frac{\theta'-\theta}{da/dt}-\frac{1}{24}\left[\frac{\theta'-\theta}{da/dt}\right]^3\frac{d^3a}{dt^3}$.

In order to be as much as possible independent of instrumental errors, some standard stars nearly on the parallel of the moon are observed at the two stations; these "moon-culminating stars" are given in the ephemerides in order to secure that both observers take the same stars. As either the preceding or the following limb, not the centre, of the moon is observed, allowance must be made for the time the semi-diameter takes to pass the meridian and for the change of right ascension during this time. This method was proposed by Pigott towards the end of the 18th century, and has been much used; but, though it may be very serviceable on journeys and expeditions to distant places where the chronometric and telegraphic methods cannot be employed, it is not accurate enough for fixed observatories. This is due, not only to the difficulties attending the observation (the difference of personal error in observing the moon and stars, the different apparent enlargement of the moon by irradiation in different telescopes and under different atmospheric circumstances, etc.), but chiefly to the large coefficient with which $\theta'-\theta$ has to be multiplied in the final equation for $\lambda'-\lambda$. Errors of four to six seconds of time have therefore frequently been noticed in longitudes obtained by this method from a limited number of observations, the longitude of the Madras observatory was for many years assumed to be $5^h\,21^m\,3.77^s$, but subsequently by a telegraphic determination this was found to be 4.37^s too great.

2. *Signals.*—In 1671 Picard determined the difference of longitude between Copenhagen and the site of Tycho Brahe's observatory by watching from the latter the covering and uncovering of a fire lighted on the top of the observatory tower at Copenhagen. Powder or rocket signals have been in use since the middle of the 18th century; they are nowadays never used for this purpose, although several of the principal observatories of Europe were connected in this manner early in the 19th century.[3]

3. *Transport of Chronometers.*—This means of determining longitude was first tried in cases where the chronometers could be brought the whole way by sea, but the improved means of communication on land led to its adoption in 1828 between the observatories at Greenwich and Cambridge, and in the following years between many other observatories. A few of the more extensive expeditions undertaken for this object deserve to be mentioned. In 1843 more than sixty chronometers were sent sixteen times backwards and forwards between Altona and Pulkowa, and in 1844 forty chronometers were sent the same number of times between

---

[1] This was probably first done in the first century by Marinus of Tyre.

[2] This proposal was chiefly dictated by a wish to facilitate the international telegraph and railway traffic. In the United States, where the large extent of the country in longitude makes it impossible to use the time of one meridian, four standard meridians were adopted in 1883, viz., 75°, 90°, 105°, 120° west of Greenwich, so that clocks showing "Eastern, Central, Mountain, or Pacific time" are exactly five, six, seven, or eight hours slower than a Greenwich mean-time clock.

[3] For instance, Greenwich and Paris in 1825 (*Phil. Trans.*, 1826). The result, $6^m\,21.6^s$, is only about 0.6^s too great.

Altona and Greenwich.[1] In 1844 the longitude of Valentia on the southwest coast of Ireland was determined by transporting thirty pocket chronometers *via* Liverpool and Kingstown and having an intermediate station at the latter place. The longitude of the United States naval observatory has been frequently determined from Greenwich. The following results will give an idea of the accuracy of the method.[2]

Previous to 1849, 373 chronometers	$5^h\ 8^m\ 12.52^s$	
Expedition of 1849, Bond's discussion	11.20^s	
“ “ Walker's “	12.06^s	
“ “ Bond's second result	12.26^s	$\pm 0.20^s$
“ 1855, 52 chronometers, 6 trips, Bond,	13.40^s	$\pm 0.19^s$

The value now accepted from the telegraphic determination is $5^h\ 8^m\ 12.09^s$. The probable errors of the results for Pulkowa-Altona and Altona-Greenwich were supposed to be $\pm 0.039^s$ and $\pm 0.042^s$. It is of course only natural that the uncertainty of the results for the trans-Atlantic longitude should be much greater, considering the length of time which elapsed between the rating of the chronometers at the observatories of Boston (Cambridge, Massachusetts) and Liverpool. The difficulty of the method consists in determining the "travelling rate." Each time a chronometer leaves the station A and returns to it the error is determined, and consequently the rate for the time occupied by the journeys from A to B and from B to A and by the sojourn at B. Similarly a rate is found by each departure from and return to B, and the time of rest at A and B is also utilized for determining the stationary rate. In this way a series of rates for overlapping intervals of time are found, from which the travelling rates may be interpolated. It is owing to the uncertainty which necessarily attaches to the rate of a chronometer during long journeys, especially by land, where they are exposed to shaking and more or less violent motion, that it is desirable to employ a great number. It is scarcely necessary to mention that the temperature correction for each chronometer must be carefully investigated, and the local time rigorously determined at each station during the entire period of the operations.

4. *Telegraphic Determination of Longitude.*—This was first suggested by the American astronomer S. C. Walker, and owed its development to the United States Coast Survey, where it was employed from about 1849. Nearly all the more important public observatories on the continent of Europe have now been connected in this way, chiefly at the instigation of the "Europäische Gradmessung," while the determinations in connection with the transits of Venus and those carried out in recent years by the American and French Governments have completed the circuit of the greater part of the globe. The telegraphic method compares the local time at one station with that at the other by means of electric signals. If a signal is sent from the eastern station A at the local time T, and received at the western station B at the local time T_1, then, if the time taken by the current to pass through the wire is called x, the difference of longitude is

$$\lambda = T - T_1 + x,$$

and similarly, if a signal is sent from B at the time T_2 and received at A at T_3, we have

$$\lambda = T_3 - T_2 - x,$$

from which the unknown quantity x can be eliminated.

The operations of a telegraphic longitude determination can be arranged in two ways. Either the local time is determined at both stations and the clocks are compared by telegraph, or the time determinations are marked simultaneously on the two chronographs at the two stations, so that further signals for clock comparison are unnecessary. The first method has to be used when the telegraph is only for a limited time each night at the disposal of the observers, or when the climatic conditions at the two stations are so different that clear weather cannot often be expected to occur at both simultaneously, also when the difference of longitude is so considerable that too much time would be lost at the eastern station waiting for the arrival of the transit record of one star from the western station before observing another star. The independent time determination also offers the advantage that the observations may be taken either by eye and ear or by the chronograph, and that the signals may be either audible beats of a relay or chronographic signals, the rule being to have observations and signals made by similar operations. The best way of using audible beats of a relay is to let the circuit pass through an auxiliary clock, which from second to second alternately makes and breaks the current, the making of the current being rendered audible by the tapping of the relays at both stations. If, now, the auxiliary and the observing clocks are regulated to a different rate, the coincidences of the beats of the relay with those of the observing clock can be noted with great accuracy, from which the difference between the two observing clocks is found. It has been proved by experience that the degree of accuracy with which the clock comparison can be made by one coincidence is exactly equal to that of one chronograph signal, the probable error being in both cases about $\pm 0.015^s$. It should, however, be mentioned that the interval between two consecutive coincidences cannot be made less than two minutes, whereas the chronograph signals may be given every second, and, as the observations made with the chronograph are also somewhat more accurate than those made by eye and ear, the chronograph should be used wherever possible. The other method, that of simultaneous registration at both stations of transits of the same stars, has also its advantages. Each transit observed at both stations furnishes a value of the difference of longitude, so that the final result is less dependent on the clock rate than in the first method, which necessitates the combination of a series of clock errors determined during the night to form a value of the clock error for the time when the exchange of signals took place. When using this method it is advisable to select the stars in such a manner that only one station at a time is at work, so that the intensity of the current can be readjusted (by means of a rheostat) between every despatch and receipt of signals. This attention to the intensity of the current is necessary whatever method is employed, as the constancy of the transmission time (x in the above equations) chiefly depends on the constancy of the current. The probable error of a difference of longitude deduced from one star appears to be[3]

for eye and ear transits $\pm 0.08^s$,
for chronograph transits $\pm 0.07^s$;

while the probable error of the final result of a carefully planned and well executed series of telegraphic longitude operations is generally between $\pm 0.015^s$ and $\pm 0.025^s$.

It is evident that the success of a determination of longitude depends to a very great extent on the accurate determination of time at the two stations, and great care must therefore be taken to determine the instrumental errors repeatedly during a night's work. But, in addition to the uncertainty which enters into the results from the ordinary errors of observation, there is another source of error which becomes of special importance in longitude work, viz., the so-called personal error. The discovery of the fact that all observers differ more or less in their estimation of the time when a star crosses one of the spider lines in the transit instrument was made by Bessel in 1820;[4] and, as he happened to differ fully a second of time from several other observers, this remarkably large error naturally caused the phenomenon to be carefully examined. Bessel also suggested what appears to be the right explanation, viz., the co-operation of two senses in observing transits by eye and ear, the ear having to count the beats of the clock while the eye compares the distance of the star from the spider line at the last beat before the transit with the distance at the first beat after it, thus estimating the fraction of second at which the transit took place. It can easily be conceived that one person may first hear and then see, while to another these sensations take place in the reverse order; and to this possible source of error may be added the sensible time required by the transmission of sensations through the nerves to the brain and for the latter to act upon them. As the chronographic method of observing dispenses with one sense (that of hearing) and merely requires the watching of the star's motion and the pressing of an electric key at the moment when the star is bisected by the thread, the personal errors should in this case be much smaller than when the eye and ear method is employed. And it is a fact that in the former method there have never occurred errors of between half and a whole second such as have not unfrequently appeared in the latter method.

In astronomical observations generally this personal error does not cause any inconvenience, so long as only one observer is employed at a time, and unless the amount of the error varies with the declination or the magnitude of the star; but when absolute time has to be determined, as in longitude work, the full amount of the personal equation between the two observers must be carefully ascertained and taken into account. And an observer's error has often been found to vary very considerably not only from year to year but even within much shorter intervals; the use of a new instrument, though perhaps not differing in construction from the accustomed one, has also been known to affect the personal error. For a number of years this latter circumstance was coupled with another which seemed perfectly incomprehensible, the personal error appearing to vary with the reversal of the instrument, that is, with the position of the illuminating lamp east or west. But in 1869–70 Hirsch noticed during the longitude operations in Switzerland that this was caused by a shifting of the reflector inside the telescope, by means of which the field is illuminated, which produced an apparent shifting of the image of the spider lines, unless the eye-piece was very accurately focused for the observer's sight. The simplest and best way to find the equation between two observers is to let one observe the transits of stars over half the wires in the telescope, and the other observe the transits over the remainder, each taking care to refocus the eye-piece for himself in order to avoid the above-mentioned source of error. The single transits reduced to the middle wire give immediately the equation; and, in order to eliminate errors in the assumed wire-intervals, each observer uses alternately the first and the second half of the wires. Another method is in vogue at Greenwich, where each observer with the transit circle from a series of stars determines the clock error and reduces this to a common epoch (0^h sid. time) by means of a clock rate found independently of personal error. The differences between the clock errors thus found are equal to the personal equations. This method cannot, however, be recommended, as the systematic errors in the right ascensions of the stars and any slight variation of the clock rate would affect the personal equation; the first method is therefore generally used in longitude work. It is advisable to let the observers compare themselves at the beginning, middle, and end of the operations and, if possible, at both the instruments employed. A useful check on the results is afforded by simultaneous experiments with one of the instruments contrived by C. Wolf, Kaiser, and others (sometimes called "time collimators" by which the absolute personal error of an observer can be determined. Though differing much in detail, these instruments are all constructed on the same principle; an artificial star (a lamp shining through a minute hole in a screen mounted on a small carriage moved by clockwork) passes in succession across a number of lines drawn on oiled paper, while an electric contact is made at the precise moment when the star is bisected on each line by the carriage passing a number of adjustable contact makers. The currents thus made register the transits automatically on a chronograph, while the observer, viewing the apparatus through his telescope, can observe the transits in the usual manner either by eye and ear or by chronograph, thus immediately finding his personal error. On the continent these contrivances have frequently been used to educate pupils learning to observe, and experience has repeatedly shown that a considerable personal error can be generally somewhat diminished through practice.

---

[1] As a great many of the chronometers used in 1844 were made by Dent and were of superior excellence, a smaller number was considered sufficient.

[2] Gould, *Transatlantic Longitude*, p. 5, Washington, 1869.

[3] Albrecht, *Bestimmung von Längendifferenzen mit Hülfe des electrischen Telegraphen*, p. 80 Leipsic, 1869, 4to.

[4] Maskelyne had in 1795 noticed that one of his assistants observed transits more than half a second later than himself, but this was supposed to arise from some wrong method of observing adopted by the assistant, and the matter was not further looked into.

Literature.—General treatises on spherical astronomy, such as Brünnow's *Lehrbuch der sphärischen Astronomie* (3d ed., Berlin, 1871; translated into English and several other languages) and Chauvenet's *Manual*, treat very fully of the numerous methods of determining time by combination of altitudes or azimuths of several stars. The best handbook of telegraphic longitude work is Albrecht's already mentioned; but any one engaging in practical work of this kind should consult the accounts of the numerous longitude determinations carried out during recent years, particularly the *Publicationen des kön. preussischen geodätischen Instituts*; *Telegraphic Determination of Differences of Longitude by Officers of the United States Navy* (Washington, 1880); *Telegr. Determ. of Longitudes in Mexico, Central America, and on the West Coast of South America* (Washington, 1885); the *Reports* of the United States Coast and Geodetic Survey; vol. ix. of the *Account of the Great Trigonometrical Survey of India*; and vol. iii. of Dun Echt observatory *Publications*. A discussion of all the investigations on personal errors up to 1875 was published by Dreyer in *Proc. R. Irish Acad.*, 2d series, vol. ii., 1876, pp. 484–528. (J. L. E. D.)

TIMOLEON. The life of Timoleon, one of the noblest and most interesting of the men of old Greece, is closely bound up with the history of SICILY (*q.v.*), and more particularly of SYRACUSE (*q.v.*), in the latter half of the 4th century B.C. It is as the champion of Greece against Carthage, and of constitutional government against violence and oppression, that he stands out as such a grand figure. His early career in his native Corinth was shaped by a tragic incident. Timoleon had saved the life of his brother, Timophanes, on the field of battle; but, when that same brother, at the head of a band of mercenary soldiers, took possession of the acropolis and made himself practically a military despot and master of the city, Timoleon, after an ineffectual protest, let him be struck down by his brother-in-law and one or two other friends who had joined in his remonstrance.[1] By the public opinion of Corinth generally his conduct was approved as patriotic; but the curses of his mother and the cold looks of some of his kinsfolk and acquaintances drove him from the city into the solitude of the fields, and there, it would seem, for some years he pined away, hating life and even bent on ending it by voluntary starvation. He must have reached middle life when, in 344 B.C., envoys came from Syracuse to Corinth to appeal to the mother-city for relief from the intestine feuds and foreign mercenaries under which the Syracusans, and all the Greeks of Sicily, suffered. Carthage, too, their old and bitter foe, after some years of quiet, was again bestirring herself and intriguing with the local despots. Corinth could not refuse her help, though her chief citizens declined the responsibility of attempting to establish a settled government in the factious and turbulent Syracuse. By a sort of Divine inspiration, says Plutarch (*Tim.*, 3), Timoleon, being named by an unknown voice in the popular assembly, was chosen by a unanimous vote to undertake the mission. He sailed for Sicily with a few of the leading citizens of Corinth and a small troop of Greek mercenaries. On arriving at Rhegium he found that his movements were watched by a Carthaginian squadron, acting under the advice of a Syracusan, Hicetas, who had made himself master of Leontina and aimed at supplanting with Carthaginian aid the younger Dionysius, still nominally tyrant of Syracuse, but actually in possession only of the island citadel. Hicetas, while seeming to favor Corinthian intervention, was really working with Carthage on behalf of the tyrants. Timoleon, however, slipped away from the Carthaginian watch and landed at Tauromenium (Taormina), where he had a very friendly reception. At Adranum, an island town, to which he came by invitation from a party among the citizens, he surprised Hicetas, and drove him back, with his troops utterly defeated, to Syracuse. The Sicilian Greeks now rallied round him, and the following year (343) saw the surrender of Dionysius and Timoleon master of the entire city. Hailed by the citizens as a heaven-sent deliverer, he at once began the work of restoration, bringing in a multitude of new settlers from the mother-city and from Greece generally, and establishing a popular government on the basis of the laws of Diocles, which had been forgotten under the Dionysian *régime*. The impress of Timoleon's reforms seems to have lasted to the days of Augustus. The tyrants, too, in the other Sicilian cities were put down, and his old enemy Hicetas went back to Leontini, where he lived as a private though powerful citizen. He made one more attempt to overthrow Timoleon, and induced Carthage to send (340–339) a great army, which landed at Lilybæum (Marsala). The Syracusans could hardly be brought to face the invader; but with a miscellaneous levy of about 12,000 men, most of them mercenaries, Timoleon marched westwards across the island into the neighborhood of Selinus and won a great and decisive victory on the Crimisus. The Carthaginian host is said to have outnumbered Timoleon's army in the proportion of seven to one. The general himself led on his infantry in person (Plut., *Tim.*, 27), and their enemy's discomfiture was completed by a blinding storm of rain and hail driven straight in their faces (Diod., xvi. 79). This victory gave the Greeks of Sicily many years of peace and safety from Carthage. Carthage made, however, one more effort and despatched some mercenaries to prolong the conflict between Timoleon and the tyrants. But it soon ended (338 B.C.) in the defeat of Hicetas, who was taken prisoner and put to death, and in a treaty which confined the dominion of Carthage in Sicily to the west of the Halycus (Platani). Timoleon, having put down the despots and given freedom to the Greek cities of Sicily, retired into private life, though he remained practically supreme not only at Syracuse but throughout Sicily. This island, notwithstanding the many elements of discord which political revolution, with the return of exiles and the influx of new settlers, must have brought in, seems to have been during Timoleon's lifetime tranquil and contented. There are some characteristic stories told of his last days. Although blind, he used to come in his car into the assembly in the theatre and give his opinion, which was commonly accepted by a unanimous vote. An officious person once insisted on his giving the ordinary bail in a lawsuit; but he replied that he had himself always been the consistent champion of law and of legal rights for them all. Again, when his military strategy was unfavorably criticised, he expressed his gratitude to heaven that he had won for the Syracusans the privilege of liberty of speech. He died in 337, and was buried at the cost of the citizens of Syracuse, who erected a grand monument to his memory in their market-place.

---

[1] [This account of the deed is Plutarch's. There are differing statements by Diodorus and Corn. Nepos.—AM. ED.]

Plutarch's *Life of Timoleon* and portions of Diodorus Siculus are our chief sources of original information. There is an admirable and most interesting account of his life and work in chap. lxxxv. of Grote's *History of Greece.*

TIMON of Athens, a noted misanthrope, lived during the Peloponnesian War. He is more than once alluded to by Aristophanes and other comedians of the Attic stage. Plutarch takes occasion to introduce a short account of his life in the biography of Mark Antony (ch. 70), and he gives his name to one of Lucian's dialogues. Shakespeare probably derived his knowledge of Timon mainly from Plutarch; but the Timon of Shakespeare resembles the Timon of Lucian in so many points that some critics think Shakespeare (or whoever wrote the first sketch of the play) must have had access to the dialogue in question.

TIMON of Phlius, the well-known sillograph and skeptic philosopher, flourished about 280 B.C. He studied philosophy under Stilpo the Megarian and Pyrrho of Elis, the famous skeptic. Thereafter he spent some time in Chalcedon, where he made a fortune by teaching and lecturing. The rest of his life was passed chiefly at Athens, where he died at an advanced age.

The writings of Timon, if we may trust Diogenes Laertius (ix. ch. 12), were exceedingly numerous both in prose and in verse: besides the Σίλλοι, he is asserted to have written epic poems, tragedies, comedies, satyric dramas, and other varieties. But he is best known as the author of the Σίλλοι or sarcastic hexameter verses written against the Greek philosophers. They were divided into three books; in the first the author spoke in his own person, while in the second and third Xenophanes of Colophon replied to inquiries addressed to him by Timon about early and late philosophers. From the fragments that remain (about 140 lines or parts of lines, printed in Mullach, *Frag. Phil. Græc.*, i. pp. 84–98) we see that Timon possessed some of the qualities of a great satirist together with a thorough command of the hexameter; but there is no trace of any loftier aim than to awaken derisive laughter. Philosophers are "excessively cunning murderers of many wise saws" (ver. 96); the only two whom he spares are Xenophanes, "the modest censor of Homer's lies" (v. 29), and Pyrrho, against whom "no other mortal dare contend" (v. 126). Besides the Σίλλοι we have some lines preserved from the Ἰνδαλμοί, a poem in elegiac verse, which appears to have inculcated the tenets of skepticism, and one or two lines or parts of lines which cannot be with certainty assigned to either poem.

TIMOR, an island of the East Indian Archipelago, the easternmost and largest of the lesser Sundanese group, stretching southwest and northeast for 300 miles between 8° 40′ and 10° 40′ S. lat. and 123° 30′ and 127° E. long. It has a mean breadth of 60 miles, an area of over 11,000 square miles, and a population roughly estimated at about 500,000. Timor lies in deep water a little to the west of the hundred-fathom line, which marks in this direction the proper limit of the shallow Arafura Sea, flowing between it and northern Australia. It differs considerably from the other members of the Sundanese group both in the lie of its main axis (southwest and northeast instead of west and east), and in the great prevalence of old rocks, such as schists, slates, sandstones, carboniferous limestones, and other more recent sedimentary formations, and in its correspondingly slighter volcanic character. It comes, however, within the great volcanic zone which sweeps in a vast curve from the northern extremity of Sumatra, through Java and the other Sundanese islands, round to Amboina, Tidor, Ternate, Jilolo, and the Philippines. There appear to be at least two quiescent and other extinct cones, and the surface is everywhere extremely rugged and mountainous, with numerous irregular ridges from 4000 to 8000 feet high, forming altogether a very confused orographic system. Mount Kabalaki in the eastern district of Manufahi rises above 10,000 feet (H. O. Forbes); the culminating point appears to be Mount Allas (11,500 feet) near the south coast. Owing to the prevalent dry easterly winds from the arid plains of North Australia, Timor, like Ombay, Flores, and other neighboring islands, has a much drier climate, with a correspondingly poorer vegetation, than Java, and has few perennial streams, and no considerable rivers. Hence, apart from almost untouched and unsurveyed stores of mineral wealth, such as iron, copper, and gold, which occur apparently in considerable quantities at several points, the island is poor in natural resources. The uplands, however, yield good wheat and potatoes, while the woodlands, which nowhere form veritable forests, contain much excellent sandalwood. This and a noted breed of hardy ponies form the chief articles of export. Owing doubtless to the zone of deep water flowing between Timor and the Arafura Sea, the fauna of Timor presents, beyond a marsupial cuscus, scarcely any Australian types. The few mammals, such as a deer, a civet, a pig, a shrew, and monkeys, as well as the birds and insects, resemble ordinary Malayan forms as met with in Java and more especially in Celebes and the Moluccas. In its natural history, as well as its physical constitution and oceanic surroundings, Timor is thus entirely separated from Australia and should perhaps be grouped with Celebes, Buru, Ceram, and Jilolo as the surviving fragments of a Miocene continent intervening between Asia and Australia, but at no time connected with either.

The bulk of the population is certainly Papuan, but intermingled in the most varied proportions with Malayan, Indonesian, and other elements; hence it presents an extraordinary diversity of physical types, as is clearly shown by the portraits figured in H. O. Forbes's *Naturalist's Wanderings in the Eastern Archipelago.* The natives, still mainly independent of their nominal Dutch and Portuguese rulers, are divided into a large number of more or less hostile tribes, speaking as many as forty distinct Papuan and Malayan languages or dialects. Some are extremely rude and still addicted to head-hunting, at least during war, and to other barbarous practices. In their *uma-luli*, or sacred (tabooed) enclosures, rites are performed resembling those of the Pacific islanders.

Politically Timor is divided between Holland and Portugal, the Dutch claiming the western section of 4500 square miles and 200,000 inhabitants, the Portuguese the eastern of nearly 6500 square miles and 300,000 inhabitants; the respective capitals, centres of government, and outports are Kupang at the western extremity and Deli on the northeast coast. But there are a large number of practically independent petty states, as many as forty-seven in the Portuguese territory alone, where they take the name of "renos," or kingdoms, under absolute "leoreis" or kinglets. The Dutch section forms with Sumba, Savu, Rotti, and the surrounding islets a residency administered by a Dutch resident stationed at Kupang, which has a population of 8000.

TIMOR LAUT ("Seaward Timor"), called also TENIMBER, an insular group in the East Indian Archipelago, forming the central and largest link in a double chain of islands which stretches from Timor through Kei and Aru to New Guinea. It lies nearly midway between Timor and Aru, and forms, not one continuous mass, as used to be supposed, but a group of three large islands,—Yamdena in the centre, separated by Wallace Channel from Larat in the north and by Egeron Strait from Selaru in the south, besides a cluster or chain of islets on the west and north sides. From one of these the name *Tenimber* appears to have been extended to the whole group, which stretches for about 100 miles southwest and northeast, nearly parallel with Timor, from which, however, it differs altogether in its physical constitution. H. O. Forbes, who surveyed Wallace Channel and the northern districts in 1882, describes it as a low coralline group seldom rising above 100 feet, except at Egeron Strait, where the cliffs are 400 feet high, and at Laibobar, apparently a volcanic islet on the west side, which has an extinct crater 2000 feet high. There are no streams, and the poor soil, covered with a typically coral island flora, yields little beyond maize—the staple food—manioc, sweet potatoes, tobacco, some sugar-cane, cotton, and a little rice. The fauna includes buffaloes in a wild state, a marsupial cuscus, some bats, the beautiful scarlet lory, new or rare varieties of the ground-thrush, honey-eater, and oriole. The birds seem to have come mainly from New Guinea, the insects from Timor, and a few of both from Australia.

The aborigines are evidently Papuans, with a language like that of the Kei Islanders; but there is a large intermingling of Malayan and perhaps Indonesian elements. They are a fine race, often over 6 feet, and, like all Papuans noted for their artistic sense, which is shown especially in their wood and ivory carvings. In other respects they are pagans in a low state of culture, mostly divided into hostile communities and addicted to piracy. The group belongs to the Dutch, who have a "post-holder" stationed at Ritabel on the west coast of Larat, a trading station of the Bughis from Celebes.

TIMOTHEUS, a distinguished Athenian general, was a son of Conon, who restored the walls of Athens. To the military qualities of his father he added a love of letters, which found scope in his friendship with Isocrates. The considerable fortune which he inherited from his father seems to have been exhausted by him in the public service. In 375 B.C. the Athenians, then at war with Sparta, sent Timotheus with a fleet to the Ionian Sea, where he gained over Cephalonia and secured the friendship of the Acarnanians and of Alcetas, king of the Molossians. He also made himself master of Corcyra, but used his victory with a moderation which won the goodwill of the conquered. At the same time he defeated a Spartan fleet at Alyzia on the Acarnanian coast. In 373 he was appointed to the command of a fleet destined for the relief of Corcyra, then beleaguered by the Spartans. But his ships were not fully manned, and to recruit their strength he first cruised in the Ægean. The delay excited the indignation of the Athenians, who brought him to trial; but, thanks to the exertions of his friends, Jason, tyrant of Pheræ, and Alcetas, king of the Molossians, both of whom came to Athens personally to plead his cause, he was acquitted, but removed from the command, Iphicrates being appointed in his room. Being reduced to great poverty—for he had pledged his private property in order to put the fleet in an efficient state—he left Athens and took service with the king of Persia. We next hear of him in 367 or 366, when he was sent by the Athenians with an armament to support Ariobarzanes, satrap of Phrygia. But finding that the satrap was in open revolt against Persia, Timotheus abstained from helping him and turned his arms against Samos, which was occupied by a Persian garrison. He took it after a ten months' siege (365 B.C.). Sailing north, he then captured Sestus, Crithote, Torone, Potidæa, Methone, Pydna, and many more cities. In 358 or 357, when Eubœa was in danger of falling into the hands of Thebes, the Athenians, in response to a spirited appeal of Timotheus, crossed over into the island and expelled the Thebans in three days. In the course of the Social War, which broke out shortly afterwards, Timotheus was despatched with Iphicrates, Menestheus, son of Iphicrates, and Chares to put down the revolt. The hostile fleets sighted each other in the Hellespont; but a gale was blowing, and Iphicrates and Timotheus decided not to engage. Chares, disregarding their opposition, lost many ships, and in his despatches he incriminated his colleagues so bitterly that the Athenians recalled them and put them on their trial for having taken bribes from the enemy to betray the fleet. The accusers were Chares and Aristophon. The former was an officer of notoriously bad character; the latter had himself stood in the dock no less than seventy-five times. Iphicrates was not above browbeating the jury, who accordingly acquitted him and his son. Timotheus, who condescended to no such means of securing an acquittal, was condemned to pay a very heavy fine. Being unable to pay, he withdrew to Chalcis. The time and place of his death are not mentioned by ancient writers. The Athenians afterwards did what they could to repair the wrong they had done to Timotheus by remitting the greater part of the fine to his son Conon, by burying his remains in the Ceramicus, and by raising statues to his memory in the agora and the acropolis.

Our materials for the life of Timotheus are very imperfect, and the chronology is in some points uncertain. The chief authorities are Isocrates, *Or.*, xv.; Xenophon, *Hellenica*, v. and vi.; Diodorus, xv. and xvi.; Cornelius Nepos, *Vit. tim.*; and Polyænus, *Strat.*, iii. 10. Other scraps are to be gleaned from the orators, Plutarch, etc. The speech *Against Timotheus* which has come down to us under the name of Demosthenes is probably not by the orator. It is chiefly interesting as illustrating the straits to which Timotheus was reduced by his sacrifices in the public cause.

TIMOTHEUS, a celebrated Greek musician and poet, was a native of Miletus, and died, according to the Parian marble, in 357 or 356 B.C., at the age of ninety. He added one or more strings (the number is uncertain) to the lyre, whereby he incurred the displeasure of the conservative Spartans. The few fragments of his poems are collected by Bergk in his *Poetæ Lyrici Græci*.

TIMOTHY, or TIMOTHEUS (Acts xvi. 1, xvii. 14, etc.), a Lycaonian, the son of a Gentile father but of a Jewish mother, Eunice (2 Tim. i. 5), became a disciple of Paul at the time of his visit to Derbe and Lystra, and in deference to Jewish feeling was circumcised. He accompanied the apostle on many of his journeys, and was employed by him on important missions (1 Thess. iii. 2; 1 Cor. iv. 17, xvi. 10). His name is associated with that of Paul in the opening salutations of both epistles to the Thessalonians, the second epistle to the Corinthians, and those to the Philippians and Colossians. He was therefore with Paul at Rome. At a later date he is mentioned in Heb. xiii. 23 as having undergone imprisonment but been released. For the epistles of Paul to Timothy, see PASTORAL EPISTLES (vol. xviii. p. 353). On the basis of them he is traditionally represented as bishop of Ephesus, and tradition also tells that he suffered under Domitian. His martyrdom is celebrated on the 24th January. The apocryphal *Acta Timothei* (Greek and Latin) have been edited by Usener (Bonn, 1877); compare Lipsius, *Apokr. Apostelgeschichten*, ii. 2 (1884).

TIMUR. TIMÚR BEY or TIMÚR LANG (*Timur i Leng*), "the lame Timur"—vulgarized into TAMERLANE—the renowned Oriental conqueror, was born in 1336 at Kesh, better known as Shahr-i-Sabz, "the green city," situated some 50 miles south of Samarkand in Transoxiana. His father Teragai was head of the tribe of Berlas. Great-grandson of Karachar Nevian (minister of Jagatai, son of Jenghiz Khan, and commander-in-chief of his forces), and distinguished among his fellow-clansmen as the first convert to Islamism, Teragai might have assumed the high military rank which fell to him by right of inheritance; but like his father Burkul he preferred a life of retirement and study. Under the paternal eye the education of young Timúr was such that at the age of twenty he had not only become an adept in manly outdoor exercises but had earned the reputation of being an attentive reader of the Koran. At this period, if we may credit the *Memoirs* (*Malfúzát*), he exhibited proofs of a tender and sympathetic nature.

About 1358, however, he came before the world as a leader of armies. His career for the next ten or eleven years may be thus briefly summarized from the *Memoirs.* Allying himself both in cause and by family connection with Kurgan, the dethroner and destroyer of Kezan, chief of the Jagatai, he was deputed to invade Khorasan at the head of a thousand horse. This was the second warlike expedition in which he was the chief actor, and the accomplishment of its objects led to further operations, among them the subjection of Khwarizm and Urganj. After the murder of Kurgan the contentions which arose among the many claimants to sovereign power were arrested by the invasion of Tughlaḳ Timúr of Kashgar, a descendant of Jenghiz. Timúr was despatched on a mission to the invader's camp, the result of which was his own appointment to the government of Máwará'lnahr (Transoxiana). By the death of his father he was also left hereditary head of the Berlas. The exigencies of his quasi-sovereign position compelled him to have recourse to his formidable patron, whose reappearance on the banks of the Sihon created a consternation not easily allayed. Máwará'lnahr was taken from Timúr and entrusted to a son of Tughlaḳ; but he was defeated in battle by the bold warrior he had replaced at the head of a numerically far inferior force. Tughlaḳ's death facilitated the work of reconquest, and a few years of perseverance and energy sufficed for its accomplishment, as well as for the addition of a vast extent of territory. During this period Timúr and his brother-in-law, Hosain—at first fellow-fugitives and wanderers in joint adventures full of interest and romance—became rivals and antagonists. At the close of 1369 Hosain was assassinated and Timúr, having been formally proclaimed sovereign at Balkh, mounted the throne at Samarkand, the capital of his dominions.

The next thirty years or so were spent in various wars and expeditions. He not only consolidated his rule at home by the subjection of intestine foes, but sought extension of territory by encroachments upon the lands of contemporary potentates. His conquests to the west and northwest led him among the Mongols of the Caspian, and to the banks of the Ural and Volga; those to the south and southwest comprehended almost every province in Persia, including Baghdad, Kerbela, and Kurdistan. To this time belong the vestiges of his presence that still remain, such as the ruined monastery at Keghut near the Aras (Araxes), the cleft stone in the church at Dayiru 'l-'Omar (M'ar Jibráil) near Mardin, and the ruinless sites of such ancient cities as Zaranj in Sistan. In 1398, when Timúr was more than sixty years of age, Farishta tells us that, "informed of the commotions and civil wars of India," he "began his expedition into that country," and on 12th September "arrived on the banks of the Indus." His passage of the river and upward march along the left bank, the reinforcement he provided for his grandson Pir Mohammed (who was invested in Multán), the capture of towns or villages accompanied, it might be, with destruction of the houses and the massacre of the inhabitants, the battle before Delhi and the easy victory, the triumphal entry into the doomed city, with its outcome of horrors,—all these circumstances belong to the annals of India. In April, 1399, some three months after quitting the capital of Mahmúd Tughlaḳ, Timúr was back in his own capital beyond the Oxus. It need scarcely be added that an immense quantity of spoil was conveyed away. According to Clavijo, ninety captured elephants were employed merely to carry stones from certain quarries to enable the conqueror to erect a mosque at Samarkand. The war with the Turks which succeeded the return from India was rendered notable by the capture of Baghdad, Aleppo, and Damascus, and especially by the defeat and imprisonment of Sultan Bayazid. This was Timúr's last campaign. Another was projected against China, but the old warrior was attacked by fever and ague when encamped on the further side of the Sihon (Syr-Daria) and died at Atrár (Otrar) on the 17th February, 1405. Markham, in his introduction to the narrative of Clavijo's embassy, states that his body "was embalmed with musk and rose water, wrapped in linen, laid in an ebony coffin, and sent to Samarkand, where it was buried." Timúr had carried his victorious arms on one side from the Irtish and the Volga to the Persian Gulf and on the other from the Hellespont to the Ganges.

Timúr's generally recognized biographers are—'Alí Yazdí, commonly called Sharifu 'd-Dín, author of the Persian *Zafarnáma*, translated by Petis de la Croix in 1722, and from French into English by J. Darby in the following year; and Ahmed ibn Mohammed ibn Abdallah, al Dimashki, al 'Ajmi, commonly called Ibn 'Arabsháh, author of the Arabic *'Ajaibu'l Makhlnkát*, translated by the Dutch Orientalist Golius in 1636. In the work of the former, as Sir William Jones remarks, "the Tartarian conqueror is represented as a liberal, benevolent, and illustrious prince"; in that of the latter he is "deformed and impious, of a low birth and detestable principles." But the favorable account was written under the personal supervision of Timúr's grandson, Ibráhím, while the other was the production of his direst enemy. Few indeed, if any, original annals of this class are written otherwise than to order, under patronage, or to serve a purpose to which truth is secondary. Among less reputed biographies or materials for biography may be mentioned a second *Zafarnáma*, by Mauláná Nizámu 'd-Dín Shanab Gházáni (Nizám Shámí), stated to be "the earliest known history of Timúr, and the only one written in his lifetime"; and vol. i. of the *Matla'u's-Sa'dain*—a choice Persian MS. work of 1495—introduced to Orientalists in Europe by Hammer, Jahrbücher, Dorn, and (notably) Quatremère. There are also the *Memoirs* (*Malfúẓát*) and *Institutes* (*Tuzukát*), of which an important section is styled *Designs and Enterprises* (*Tadbírát wa Kangáshahá*). Upon the genuineness of these doubt has been thrown. The circumstance of their alleged discovery and presentation to Shah Jahán in 1637 was of itself open to suspicion. Alhazen, quoted by Purchas in his quaint notice of Timúr, and referred to by Sir John Malcolm, can hardly be accepted as a serious authority. His assumed memoir was printed for English readers in 1597 by William Ponsonby under the title of a *Historie of the Great Emperor Tamerlan, drawn from the ancient monuments by Messire Jean du Bec, Abbot of Mortimer;* and another version of the same book is to be found in the *Histoire du Grand Tamerlan*, by De Sainctyon, published at Amsterdam in 1678. But, although the existence of this Alhazen of Jean de Bec has been believed by many, the more trustworthy critics consider the history and historian to be equally fictitious.

Reference may be made to two more sources of information. (1) Supposed likenesses of Timúr are to be found in books and in the splendid collection of Oriental manuscripts and drawings in the British Museum. One contained in the *Shah Jahán Náma*—a gorgeous specimen of illuminated Persian manuscript and exquisite caligraphy—represents a most ordinary, middle-aged Oriental, with narrow black whisker fringing the cheek and meeting the tip of the chin in a scanty, pointed beard; a thin moustache sweeps in a semicircle from above the upper lip; the eyebrow over the almond-shaped eye is marked but not bushy. But it were vain to seek for an expression of genius in the countenance. Another portrait is included in a set of sketches by native artists, some of which, taken probably from life, show great care and cleverness. Timúr is here displayed as a stoutish, long-bodied man, below the middle-height, in age and feature not unlike the first portrait, but with thicker and more straggling hair, and distincter, though not more agreeable character in the facial expression, yet not a sign of power, genius, or any elements of grandeur or celebrity. The uncomfortable figure in the Bodleian Library does not give much help. Sir John Malcolm has been at some pains to invest his portrait of Timúr with individuality. But an analysis of his results leaves the reader in more perplexity than satisfaction at the kind of information imparted, and he reverts insensibly to the sources from which his instructor has himself been instructed. (2) As regards plays, in Marlowe's *Tamburlaine* Timúr is described as tall of stature, straightly fashioned, large of limb, having joints strongly knit, long and sinewy arms, a breadth of shoulders to "bear old Atlas's burden," pale of complexion, and with "amber hair wrapp'd in curls." The outline of this description might be from Sharifu 'd-Dín, while the colors are the poet's own. A Latin memoir of Tamerlane by Perondinus, printed in 1600, entitled *Magni Tamerlanis Scytharum Imperatoris Vita*, describes Timúr as tall and bearded, broad-chested and broad-shouldered, well-built but lame, of a fierce countenance, and with receding eyes, which express cruelty and strike terror into the lookers-on. But Jean du Bec's account of Timúr's appearance is quite different. Now *Tamburlaine* was written in 1586. The first English translation of Jean du Bec is dated in 1595, the *Life* by Perondinus in 1600, and Petis de la Croix did not introduce Sharifu 'd-Dín or 'Alí Yazdí to European readers till 1722. The dramatist must have heard of Timúr in other quarters, equally reliable it may be with those available in the present stage of Oriental research. At the beginning of the 18th century Timúr was represented in Rowe's *Tamerlane* as a model of valor and virtue. The plot, however, has little to do with history, and is improbable and void of interest. By Matthew Gregory Lewis again "Timour" is depicted as the conventional tyrant of a gorgeous melodrama, slaying, burning, slaughtering, and committing every possible atrocity until checked by violent death and a poetical climax.

Apart from modern European *savants* and historians, and the more strictly Oriental chroniclers who have written in Persian, Turkish, or Arabic, the following authorities may be cited: Laonicus Chalcondylas, Joannes Leunclavius, Joachimus Camerarius, Petrus Perondinus, Lazaro Soranzo, Simon Mairlus, Matthew Michiovius. A score or so of other names are given by Samuel Purchas. See also Clements Markham's *Clavijo*, in the Hakluyt Society's publications; White's edition of Davy's translation of the *Institutes* (1783); Stewart's translation of the *Malfúẓát*; Malcolm's *History of Persia*; and *Trans. Roy. Soc.*, 1885. (F. J. G.)

TIN (Lat. *stannum*, whence the chemical symbol "Sn"; atomic weight = 117.6, O = 16), being a component of bronze, was used as a metal thousands of years prior to the dawn of history. But it does not follow that prehistoric bronzes were made of metallic tin. When the unalloyed metal was first introduced cannot be ascertained with certainty. All we know is that about the 1st century the Greek word κασσίτερος designated tin, and that tin was imported from Cornwall into Italy after, if not before, the invasion of Britain by Julius Cæsar. From Pliny's writings it appears that the Romans in his time did not realize the distinction between tin and lead; the former was called *plumbum album* or *candidum* to distinguish it from *plumbum nigrum* (lead proper). The word *stannum* definitely assumed its present meaning in the 4th century (H. Kopp).

Grains of metallic tin occur as a subordinate admixture in the gold ores of Siberia, Guiana, and Bolivia. Of tin mineral compounds (which are not numerous) tinstone, SnO_2, is the most important; besides it only tin pyrites, which, according to Rammelsberg, exists in two varieties, $FeCu_2SnS_4$ and $ZnFeCu_4Sn_2S_8$, need be named here.

Tinstone or Cassiterite.—This native oxide of tin, SnO_2, forms very hard quadratic crystals of specific gravity 6.8. The pure mineral is colorless, and it is very scarce; most specimens are brown owing to the presence of ferric or manganic oxide. The faces of the crystals exhibit diamond lustre. There is also another native form, known as "wood tin," occurring in roundish masses with a fibrous radiating fracture. The ore is found in veins or layers within the older crystalline rocks and slates. Being much more highly proof against the action of water and carbonic acid than its matrix, the ore often presents itself in loose crystals as part of the sand of rivers (stream tin). The oldest known deposit of tinstone is that of Cornwall, where it occurs in granite and in the "killas" (a kind of metamorphic clayish slate), associated with wolframite, apatite, topaz, mica, tourmaline, arsenide of iron, and other minerals. Cornish tin ore is characteristically rich in arsenic. Minor European deposits occur in the Erzgebirge, in Brittany, and in Galicia (Spain). A very considerable deposit of pure ore (chiefly stream tin) exists in the island of Banca; and in Malacca tinstone is found. Other relatively abundant deposits occur in Bolivia and Peru, and in Queensland and New South Wales (lately discovered).

Metallurgy.—In the extraction of tin from tinstone ore the first step is to pound the crude ore and wash away the lighter gangue with water (see METALLURGY, vol. xvi. p. 64). The washed ore is "roasted" to burn away the arsenic and sulphur and to convert the iron, originally present in the heavy and compact form of pyrites or arsenide, into light friable oxide, which is removed by a second washing process. If much oxide of copper is contained in the product, it is extracted with dilute sulphuric acid, and from the solution is recovered by precipitation with metallic iron (see COPPER, vol. vi. p. 310). The purified ore, known as "black tin," goes to the smelting furnace. During the roasting process the ore must be constantly agitated to prevent caking, and to bring the arseniferous, etc., parts to the surface. To save manual labor, Oxland and Hocking have constructed a mechanical roaster. It consists of a slanting tube of boiler-iron, coated inside with fire-brick. The lower end opens into the fire-place; the upper communicates with a set of chambers for the condensation of the white arsenic produced. The washed ore, after being dried on the top of the chamber, is run thence by a funnel into the pipe, which is made to rotate about its axis from three to eight times per minute. Before the ore has travelled far down the arsenic and sulphur catch fire, and by the time it reaches the bottom it is fully roasted. It falls into a receptacle below the level of the fire. Of the impurities of the ore the wolframite (tungstate of iron and manganese) is the most troublesome, because on account of its high specific gravity it cannot be washed away as gangue. To remove it, Oxland fuses the ore with a certain proportion of carbonate of soda, which suffices to convert the tungsten into soluble alkaline tungstate, without producing noteworthy quantities of soluble stannate from the oxide of tin; the tungstate is easily removed by treatment with water.

Smelting.—The purified ore is mixed with about one-fifth of its weight of anthracite smalls, the mixture being moistened to prevent it from being blown off by the draught, and is then fused on the sole of a reverberatory furnace for five or six hours. The slag and metal produced are then run off and the latter is cast into bars; these are in general contaminated with iron, arsenic, copper, and other impurities. To refine them, the bars are heated cautiously on an inclined hearth, when relatively pure tin runs off, while a skeleton of impure metal remains. The metal run off is further purified by *poling*, *i.e.*, by stirring it with the branch of a tree,—the apple tree being preferred traditionally. This operation is no doubt intended to remove the oxygen diffused throughout the metal as oxide, part of it perhaps chemically by reduction of the oxide to metal, the rest by conveying the finely diffused oxide to the surface and causing it to unite there with the oxide scum. After this the metal is allowed to rest for a time in the pot at a temperature above its freezing point and is then ladled out into ingot forms, care being taken at each stage to ladle off the top stratum. The original top stratum is the purest, and each succeeding lower stratum has a greater proportion of impurities; the lowest consists largely of a solid or semi-solid alloy of tin and iron.

To test the purity of the metal, the tin-smelter heats the bars to a certain temperature just below the fusing point, and then strikes them with a hammer or lets them fall on a stone floor from a given height. If the tin is pure it splits into a mass of granular strings. Tin which has been thus manipulated and proved incidentally to be very pure is sold as grain tin. A lower quality goes by the name of block tin. Of the several commercial varieties Banca tin is the purest; it is indeed almost chemically pure. Next comes English grain tin. For the preparation of chemically pure tin two methods are employed. (1) Commercially pure tin is treated with nitric acid, which converts the tin proper into an insoluble hydrate of SnO_2, while the copper, iron, etc., become nitrates; the oxide is washed first with dilute nitric acid, then with water, and is lastly dried and reduced by fusion with black flux or cyanide of potassium. (2) A solution of pure stannous chloride in very dilute hydrochloric acid is reduced with a galvanic current. According to Stolba, beautiful crystals of pure tin can can be obtained as follows. A platinum basin, coated over with wax or paraffin outside, except a small circle at the very lowest point, is placed on a plate of amalgamated zinc, lying on the bottom of a beaker, and is filled with a solution of pure stannous chloride. The beaker also is cautiously filled with acidulated water up to a point beyond the edge of the platinum basin. The whole is then left to itself, when crystals of tin gradually separate out on the bottom of the basin.

Properties of Pure Tin.—An ingot of pure tin is pure white (except for a slight tinge of blue); it exhibits considerable lustre and is not subject to tarnishing on exposure to normal air. The metal is pretty soft and easily flattened out under the hammer, but almost devoid of tenacity. That it is elastic, within narrow limits, is proved by its clear ring when struck with a hard body under circumstances permitting of free vibration. The specific gravity of ingot tin is 7.293 at 13° C. [55.4° F.] (Matthiessen). A tin ingot, though seemingly amorphous, has a crystalline structure, consisting of an aggregate of quadratic octahedra; hence the characteristic crackling noise which a bar of tin gives out when being bent. This structure can be rendered visible by superficial etching with dilute acid. As the minuter crystals dissolve more quickly than the larger ones, the surface assumes a frosted appearance (*moirée métallique*), not unlike that of a frozen window-pane in winter time. Its crystalline structure must account for the striking fact that the ingot, when exposed for a sufficient time to very low temperatures, (to — 39° C. [—38° F.] for 14 hours), becomes so brittle that it falls into powder under a pestle or hammer; it indeed sometimes crumbles into powder spontaneously. At ordinary temperatures tin proves fairly ductile under the hammer, and its ductility seems to increase as the temperature rises up to about 100°C. [212° F.]. At some temperature near its fusing point it becomes brittle (*vide supra*), and still more brittle from — 14° C. [6.8° F.] downwards. This behavior of the metal may probably be explained by assuming that in any tin crystal the coefficient of thermic expansion has one value in the direction of the principal axis and another in that of either of the subsidiary axes. From 0° to 100° [32° to 212° F.] the two coefficients are practically identical; below —14° [6.8° F.] and from somewhere above 100° C. [212° F.] upwards they assume different values; and, as the several crystals are oriented in a lawless fashion, this must tend to disintegrate the mass. Tin fuses at 232.7° [450.86° F.] (Persoz); at a red heat it begins to volatilize slowly; at 1600° to 1808° C. [2912° to 3286.4° F.] (Carnelley and Williams) it boils. The hot vapor produced combines with the oxygen of the air into white oxide, SnO_2.

Industrial Applications.—Commercially pure tin is used (principally in Germany) for the making of pharmaceutical apparatus, such as evaporating basins for extracts, infusion pots, stills, etc. It is also employed for making two varieties of tin-foil,—one for the silvering of mirrors (see MIRROR, vol. xvi. p. 523), the other for wrapping up chocolate, toilet soap, tobacco, etc. The mirror foil must contain some copper to prevent it from being too readily amalgamated by the mercury. For making tin-foil the metal is rolled into thin sheets, pieces of which are beaten out with a wooden mallet. As pure tin does not tarnish in the air and is proof against acid liquids, such as vinegar, lime juice, etc., it is utilized for culinary and domestic vessels. But it is expensive, and tin vessels have to be made very heavy to give them sufficient stability of form; hence it is generally employed merely as a protecting coating for utensils made essentially of copper or iron. The tinning of a copper basin is an easy operation. The basin, made scrupulously clean, is heated over a charcoal fire to beyond the fusing point of tin. Molten tin is then poured in, a little powdered sal-ammoniac added, and the tin spread over the inside with a bunch of tow. The sal-ammoniac removes the last unavoidable film of oxide, leaving a purely metallic surface, to which the tin adheres firmly. For tinning small objects of copper or brass (*i.e.*, pins, hooks, etc.) a wet-way process is followed. One part of cream of tartar, two of alum, and two of common salt are dissolved in boiling water, and the solution is boiled with granulated metallic tin (or, better, mixed with a little stannous chloride) to produce a tin solution; and into this the articles are put at a boiling heat. In the absence of metallic tin there is no visible change; but, as soon as the metal is introduced, a galvanic action sets in and the articles get coated over with a firmly adhering film of tin. Tinning wrought iron is effected by immersion. The most important form of the operation is making tinned from ordinary sheet iron (making what is called "sheet tin"). The iron plates, having been carefully cleaned with sand and muriatic or sulphuric acid, and lastly with water, are plunged into heated tallow to drive away the water without oxidation of the metal. They are next steeped in a bath, first of molten ferruginous, then of pure tin. They are then taken out and kept suspended in hot tallow to enable the surplus tin to run off. The tin of the second bath dissolves iron gradually and becomes fit for the first bath. To tin cast-iron articles they must be decarburetted superficially by ignition within a bath of ferric oxide (powdered hæmatite or similar material), then cleaned with acid, and tinned by immersion, as explained above. By far the greater part of the tin produced metallurgically is used for making tin alloys, the majority of which have been treated of in preceding articles; see LEAD, vol. xiv. p. 378; PEWTER, vol. xviii. p. 738; BRONZE, vol. iv. p. 330; PHOSPHORUS, vol. xviii. p. 827.

Tin Compounds.—The most important of these may be arranged into two classes, namely, stannous compounds, SnX_2, and stannic compounds, SnX_4, where X stands for Cl, Br, ½O, etc. Stannous compounds are, in general at least, characteristically prone to pass into the stannic form by taking up additional X_2 in the form of oxygen, chlorine, etc.

Stannous Chloride, , $SnCl_2$.—This can be obtained pure only by heating pure tin in a current of pure dry hydrochloric acid gas. It is a white solid, fusing at 250° C. [482° F.] and volatilizing at a red heat in nitrogen, a vacuum, or hydrochloric acid, without decomposition. The vapor density below 700° C. [1292° F.] corresponds to Sn_2Cl_4, above 800° C. [1472° F.] to nearly $SnCl_2$ (Von Meyer and Züblin). The chloride readily combines with water into an easily soluble crystallizable hydrate ("tin crystals"). This is made without difficulty by dissolving tin in strong hydrochloric acid and allowing it to crystallize. For its industrial preparation Nöllner passes sufficiently hydrated hydrochloric acid gas over granulated tin contained in stoneware bottles and evaporates the concentrated solution produced in tin basins over granulated tin. The basin itself is not attacked. The crystals contain one H_2O according to Berzelius, while Marignac finds two; probably both are right. The crystals are very soluble in cold water, and if the salt is really pure a small proportion of water forms a clear solution; but on adding much water most of the salt is decomposed, with the formation of a precipitate of oxy-chloride—

$$2SnCl_2 + 3H_2O = 2HCl + Sn_2OCl_2.2H_2O.$$

According to Michel and Kraft, one litre of cold saturated solution of tin crystals weighs 1827 grammes and contains 1333 grammes of $SnCl_2$. The same oxy-chloride is produced when the moist crystals, or their solution, are exposed to the air; by the action of the atmospheric oxygen

$$O + 3SnCl_2 = Sn_2Cl_2O + SnCl_4.$$

Hence all tin crystals as kept in the laboratory give with water a turbid solution, which contains stannic in addition to stannous chloride. The complete conversion of stannous into stannic chloride may be effected by a great many reagents,—for instance, by chlorine (bromine, iodine) readily; by mercuric chloride, $HgCl_2$, in the heat, with precipitation of calomel, HgCl, or metallic mercury; by ferric chloride in the heat, with formation of ferrous salt, $FeCl_2$; by arsenious chloride in strongly hydrochloric solutions, with precipitation of chocolate-brown metallic arsenic. All these reactions are available as tests for stannosum or the respective agents. In opposition to stannous chloride, even sulphurous acid (solution) behaves as an oxidizing agent. If the two reagents are mixed, a precipitate of yellow stannic sulphide is produced. By first intention

$$SO_3H_2 + 3Sn^{II}Cl_2 = 3Sn^{IV}Cl_2O + H_2S.$$

The stannic oxy-chloride readily exchanges its O for Cl_2 at the expense of the hydrochloric acid, which is always present, and the H_2S decomposes one-half of a molecule of $SnCl_4$ with formation of SnS_2. A strip of metallic zinc when placed in a solution of stannous chloride precipitates the tin in crystals and takes its place in the solution. Stannous chloride is largely used in the laboratory as a reducing agent, in dyeing as a mordant.

Stannous Oxide.—This as a hydrate is obtained from a solution of stannous chloride by addition of carbonate of soda; it forms a white precipitate, which can be washed with air-free water and dried at 80° C. [176° F.] without much change by oxidation. If the hydrate is heated in carbonic acid, the black anhydride SnO remains (Otto). Precipitated stannous hydrate dissolves readily in caustic potash ley; if the solution is evaporated quickly, it suffers decomposition, with formation of metal and stannate,

$$2SnO + K_2O = SnO_2K_2O + Sn.$$

If it is evaporated slowly, anhydrous stannous oxide crystallizes out at a certain stage (Otto). Dry stannous oxide, if touched with a glowing body, catches fire and burns into binoxide, SnO_2. Stannous oxalate when heated by itself in a tube leaves stannous oxide (Liebig).

Stannic chloride, $SnCl_4$, is obtained by passing dry chlorine over granulated tin contained in a retort; the tetrachloride distils over as a heavy liquid, from which the excess of chlorine is easily removed by shaking with a small quantity of tin filings and re-distilling. It is a colorless fuming liquid of specific gravity 2.269 at 0° [32° F.] (Pierre) and 2.234 at 15° C. [59° F.] (Gerlach), is fluid at $-29°$ C. [$-20°$ F.], and boils at 115.4° C. [239.7° F.] under 753.1 mm. pressure (Pierre). The chloride unites energetically with water into crystalline hydrates (ex. $SnCl_4,3H_2O$), easily soluble in water. It combines readily with alkaline and other chlorides into double salts: thus $SnCl_4 + 2KCl = SnCl_6K_2$, analogous to the chloro-platinate; another example is the salt $SnCl_6(NH_4)_2$, known industrially as "pink salt," because it is used as a mordant to produce a pink color. The plain chloride solution is similarly used. It is usually prepared by dissolving the metal in aqua regia.

Stannic Oxide, SnO_2.—This, if the term is taken to include the hydrates, exists in a variety of forms. (1) *Tinstone* (see above) is proof against all acids. Its disintegration for analytical purposes can be effected by fusion with caustic alkali in silver, with the formation of soluble stannate, or by fusion with sulphur and carbonate of soda, with the formation of a soluble thio-stannate, $SnS_2 + xNa_2S$. (2) A similar oxide is produced by burning tin in air at high temperatures or exposing any of the hydrates to a strong red heat. Such *tin-ash*, as it is called, is used for the polishing of optical glasses. (3) *Meta-stannic acid* (H_2OSn_2O, generally written $H_{10}Sn_5O_{15}$, to account for the complicated composition of metastannates, *e.g.*, the soda salt $H_8Na_2Sn_5O_{15}$) is the white hydrate produced from the metal by means of nitric acid. It is insoluble in water and in nitric acid and apparently so in hydrochloric acid; but if heated with this last for some time it passes into a hydrochlorate, which, after the acid mother liquor has been decanted off, dissolves in water. The solution when subjected to distillation behaves pretty much like a physical solution of the oxide in hydrochloric acid, while a solution of ortho-stannic acid in hydrochloric acid behaves like a solution of $SnCl_4$ in water, *i.e.*, gives off no hydrochloric acid and no precipitate of hydrated SnO_2. (4) *Ortho-stannic acid* is obtained as a white precipitate on the addition of carbonate of soda or the exact quantity of precipitated carbonate of lime to a solution of the chloride. This hydrate, SnO_2H_2O, is readily soluble in acids forming stannic salts, and in caustic potash and soda, with the formation of ortho-stannates. Of these stannate of sodium, Na_2SnO_2, is produced industrially by heating tin with Chili saltpetre and caustic soda, or by fusing very finely powdered tinstone with caustic soda in iron vessels. A solution of the pure salt yields fine prisms of the composition $Na_2SnO_3 + 10H_2O$, which effloresce in the air. The salt is much used as a mordant in dyeing and calico-printing. Alkaline and other stannates when treated with aqueous hydrofluoric acid are converted into fluostannates (*e.g.*, K_2SnO_3 into K_2SnF_6), which are closely analogous to, and isomorphous with, fluo-silicates.

Sulphides.—If tin is heated with sulphur the two unite very readily into stannous sulphide, SnS, a lead-gray mass, which under the circumstances refuse to take up more sulphur. But, if a mixture of tin (or, better, tin amalgam), sulphur, and sal-ammoniac in proper proportions be heated, stannic sulphide, SnS_2, is produced in the beautiful form of *aurum musivum* (mosaic gold),—a solid consisting of golden yellow, metallic lustrous scales. It is used chiefly as a yellow "bronze" for plaster-of-Paris statuettes, etc.

Analysis.—Tin compounds when heated on charcoal with carbonate of soda in the reducing blowpipe flame yield metal and a scanty ring of white SnO_2. The reduction, however, succeeds better with cyanide of potassium as a flux. Stannous salt solutions yield a brown precipitate of SnS with sulphuretted hydrogen, which is insoluble in cold dilute acids and in real sulphide of ammonium, $(NH_4)_2S$; but the yellow, or the colorless reagent on addition of sulphur, dissolves the precipitate as SnS_2 salt. The solution on acidification yields a yellow precipitate of this sulphide. Stannic salt, $SnCl_4$, solutions give a yellow precipitate of SnS_2 with sulphuretted hydrogen, which is insoluble in cold dilute acids but readily soluble in sulphide of ammonium, and is re-precipitated therefrom as SnS_2 on acidification. Only stannous salts (not stannic) give a precipitate of calomel in mercuric chloride solution. A mixture of stannous and stannic chloride, when added to a sufficient quantity of solution of chloride of gold, gives an intensely purple precipitate of gold purple (purple of Cassius),—a compound which, although known for centuries, is to this day little understood chemically. It behaves on the whole like a compound of Sn_2O_3 with Au_2O. The test is very delicate, although the color is not in all cases a pure purple.

(W. D.)

TINAMOU, the name given in Guiana to a certain bird as stated in 1741 by Barrere (*France Equinoxiale*, p. 138), from whom it was taken and used in a more general sense by Buffon (*Hist. Nat. Oiseaux*, iv. p. 502). In 1783 Latham (*Synopsis*, ii. p. 724) adopted it as English, and in 1790 (*Index*, ii. p. 633) Latinized it *Tinamus*, as the name of a new and distinct genus. The "Tinamou" of Barrere has been identified with the "Macucagua" described and figured by Marcgrave in 1648, and is the *Tinamus major* of modern authors.[1]

Buffon and his successors saw that the Tinamous, though passing among the European colonists of South America as "Partridges," could not be associated with those birds, and Latham's step, above mentioned, was generally approved. The genus he had founded was usually placed among the *Gallinæ*, and by many writers was held to be allied to the Bustards, which, it must be remembered, were then thought to be "Struthious." Indeed the likeness of the Tinamou's bill to that of the RHEA (vol. xx. p. 519) was remarked in 1811 by Illiger. On the other hand L'Herminier in 1827 saw features in the Tinamou's sternum that in his judgment linked the bird to the *Rallidæ*. In 1830 Wagler (*Nat. Syst. Amphibien*, etc., p. 127) placed the Tinamous in the same Order as the Ostrich and its allies; and, though he did this on very insufficient grounds, his assignment has turned out to be not far from the mark, as in 1862 the great affinity of these groups was shown by Prof. Parker's researches, which were afterwards printed in the Zoological *Transactions* (v. pp. 205–232, 236–238, pls. xxxix.–xli.), and was further substantiated by him in the *Philosophical Transactions* (1866, pp. 174–178, pl. xv.). Shortly after this Prof. Huxley in his often-quoted paper in the Zoological *Proceedings* (1867, pp. 425, 426) was enabled to place the whole matter in a clear light, urging that the Tinamous formed a very distinct group of birds which, though not to be removed from the *Carinatæ*, presented so much resemblance to the *Ratitæ* as to indicate them to be the bond of union between those two great divisions.[2] The group, from the resemblance of its palatal characters to those of the EMEU (vol. viii. p. 157), *Dromæus*, he called *Dromæognathæ*, and his decision, if not his name, has since been widely accepted.

The Tinamous thus—by whatever name we call them, *Dromæognathæ*, *Tinami*, or *Crypturi*—will be seen to be of great importance from a taxonomer's point of view, though in regard to numbers they are comparatively insignificant. In 1873 Messrs. Sclater and Salvin in their *Nomenclator* (pp. 152, 153) recognized nine genera and thirty-nine species, since which time about half a dozen other species may have been described; but in 1880 Schlegel (*Mus. Pays-Bas*, viii., Monogr. 41, pp. 1–51) would only admit five genera and thirty-one species—the latter because it was the number possessed by the Leyden museum. They are peculiar to the Neotropical Region—four species only finding their way into southern Mexico and none beyond. Some of them inhabit forests and others the more open country; but setting aside size (which in this group varies from that of a Quail to that of a large common Fowl) there is an unmistakable uniformity of appearance among them as a whole, so that almost anybody having seen one species of the group would always recognize another. Yet in minor characters there is considerable difference among them; and first of all the group may be divided into two sub-families, the first, *Tinaminæ*, having four toes, and the second, *Tinamotidinæ*, having but three—the latter containing, so far as is known, but two genera, *Calopezus* and *Tinamotis*, each consisting of a single species, while the former, according to Messrs. Sclater and Salvin (*ut supra*), may be separated into seven genera, two being *Tinamus* and *Nothocercus*, characterized by the roughness of their posterior tarsal scales, the others, *Crypturus*, *Rhynchotus*, *Nothoprocta*, *Nothura*, and *Taoniscus*, having smooth legs.

---

[1] Brisson and after him Linnæus confounded this bird, which they had never seen, with the TRUMPETER (*q.v.*).

[2] M. Alix also has from an independent investigation of the osteology and myology of *Nothura major* come to virtually the same conclusion (*Journ. de Zoologie*, iii. pp. 169 and 252, pls. viii.–xi.).

Rufous tinamou (*Rhynchotus rufescens*).

To the ordinary spectator Tinamous have much the look of Partridges, but the more attentive observer will notice that their elongated bill, their small head and slender neck, clothed with very short feathers, give them a different air. The plumage is generally inconspicuous: some tint of brown, ranging from rufous to slaty, and often more or less closely barred with a darker shade or black, is the usual style of coloration; but some species are characterized by a white throat or a bay breast. The wings are short and rounded, and in some forms the feathers of the tail, which in all are hidden by their coverts, are soft. In bearing and gait the birds show some resemblance to their distant relatives the *Ratitæ*, and Mr. Bartlett shows (*Proc. Zool. Society*, 1868, p. 115, pl. xii.) that this is especially seen in the newly-hatched young. He also notices the still stronger Ratite character, that the male takes on himself the duty of incubation. The eggs are very remarkable objects, curiously unlike those of other birds; and, as before stated (BIRDS, vol. iii. p. 671), their shell[1] looks as if it were of highly-burnished metal or glazed porcelain, presenting also various colors, which seem to be constant in the particular species, from pale primrose to sage-green or light indigo, or from chocolate-brown to pinkish orange. All who have eaten it declare the flesh of the Tinamou to have a most delicate taste, as it has a most inviting appearance, the pectoral muscles being semi-opaque. Of their habits not much has been told. Darwin (*Journal*, chap. iii.) has remarked upon the silliness they show in allowing themselves to be taken, and this is wholly in accordance with what Prof. Parker observes of their brain capacity, and is an additional testimony to their low morphological rank. At least one species of Tinamou has bred not unfrequently in confinement, and an interesting account of what would have been a successful attempt by Mr. John Bateman to naturalize this species, *Rhynchotus rufescens*, in England, at Brightlingsea in Essex, appeared in the *The Field* (23d Feb., 1884, and 12th Sept., 1885). The experiment unfortunately failed owing to the destruction of the birds by foxes. (A. N.)

TINDAL, MATTHEW (1656–1733), one of the ablest and most popular of the English deists, the son of a clergyman, was born at Beer Ferris, Devonshire, in 1656. He studied law at Lincoln College, Oxford, where he came under the influence of the High Churchman George Hickes, dean of Worcester; and in his twenty-second year he was elected fellow of All Souls College, and held his fellowship till his death. About 1685 he saw "that upon his High Church notions a separation from the Church of Rome could not be justified," and accordingly he joined the latter. But, discerning the baselessness and absurdity of Rome's claims, he returned to the Church of England at Easter 1688. In 1694 he published an *Essay of Obedience to the Supreme Powers*, in which he justified the Revolution against notions of passive obedience and *jus divinum*; in 1697 an *Essay on the Power of the Magistrate and the Rights of Mankind in Matters of Religion*, an able vindication of liberty of conscience, though he allows no right of toleration to "atheists"; and in 1698 an essay on *The Liberty of the Press*, a vigorous exposure of the proposal to appoint licensers of the press and a powerful plea for the free discussion of religion. The first of his two larger works, *The Rights of the Christian Church associated against the Romish and all other priests who claim an independent power over it*, part i., appeared anonymously in 1706 (2d ed., 1706; 3d, 1707; 4th, 1709). The book was regarded in its day as an extremely forcible defence of the Erastian theory of the supremacy of the state over the church, and at once provoked a storm of counter-argument and abuse on the part of those who maintained the independent rights and authority of the church. The law also was invoked against it, and, after several attempts to proscribe the work had failed, one against the author, publisher, and printer succeeded on 12th December, 1707, and another against a bookseller for selling a copy the next day. The prosecution did not prevent the issue of a fourth edition and gave the author the opportunity of issuing *A Defence of the Rights of the Christian Church*, in two parts (2d ed., 1709). The book continued to be the subject of denunciation for years, and Tindal believed he was charged by Dr. Gibson, bishop of London, in a *Pastoral Letter*, with having undermined religion and promoted atheism and infidelity, — a charge to which he replied in an anonymous tract, *An Address to the Inhabitants of London and Westminster*, a second and larger edition of which appeared in 1730. In this tract[2] he makes a valiant defence of the deists and of the use of reason in religious matters, and anticipates here and there his *Christianity as Old as the Creation; or the Gospel a Republication of the Religion of Nature*, London, 1730 (2d ed., 1731; 3d, 1732; 4th, 1733), which was regarded by friends and foes alike as the "Bible" of deism. It was really only the first part of the whole work, and the second, though written and entrusted in manuscript to a friend, never saw the light. It was said that Dr. Gibson prevented its publication. The first part made a great noise, and the answers to it were numerous, the most able being by Dr. James Foster (1730), Dr. John Conybeare (1732), Dr. John Leland (1733), and Bishop Butler (1736). It was translated into German by J. Lorenz Schmidt (1741), and from it dates the influence of English deism on German theology. It is by this book that Tindal is now chiefly remembered; but he had probably adopted substantially the principles it expounds before he wrote his essay of 1697. He objected to be called a simple deist, and claimed the name of "Christian deist," as he held that true Christianity is identical with the eternal religion of nature. He died at Oxford on 16th August, 1733.

---

[1] Herr von Nathusius has described its microscopic structure (*Journ. für wissensch. Zoologie*, 1871, pp. 330–355).

[2] *A Second Address to the Inhabitants*, etc., with replies to some of the critics of that book, bears the same date, 1730, though some of the works it refers to appeared in 1731.

The religious system expounded in Tindal's *Christianity as Old as the Creation*, unlike the earlier system of Lord Herbert of Cherbury, was based on the empirical principles of Locke's philosophy. It assumed the traditional deistic antitheses of external and internal, positive and natural, revelations and religions, and perpetuated at the same time the prevalent misconceptions as to the nature of religion and revelation. The system was, moreover, worked out by the purely *a priori* method, with all but a total disregard of the facts of religious history. It starts from the tremendous assumptions that true religion must, both from the nature of God and the nature of things, be eternal, universal, simple, and perfect; it maintains that this religion can consist of nothing but the simple and universal duties towards God and man, the first consisting in the fulfilment of the second,—in other words, the practice of morality. The author's moral system is somewhat confused and inconsistent, but is essentially utilitarian. From such principles it follows necessarily that the true revealed religion can be nothing more nor less than a republication of the religion of nature or reason, and that, if Christianity is the perfect religion, it can only be that republication, and must be as old as the creation. The special mission of Christianity, therefore, was simply to deliver men from the superstition which had in course of time got mixed up with the religion of nature. True Christianity consequently must be a perfectly "reasonable service"; arbitrary and positive precepts can form no true part of it; revelation and reason can never disagree; reason must be supreme, and the Scriptures as well as all religious doctrines must submit to its tests; and only such writings can be regarded as Divine Scripture which tend to the honor of God and the good of man. Thus tested, much in the Old and the New Testaments must be rejected as defective in morality or erroneous in fact and principle. The strength of Tindal's position was the underlying conviction of the essential harmony between man's religious and rational nature, and consequently of the rationality of Christianity. Its weakness was that, like the whole religious philosophy of the time, it was founded on a total misconception of the nature of religion and of revelation, and on as complete a disregard of the course of man's religious development. Weak points in it were ably exposed by Foster, Conybeare, Butler, and others; but its radical errors needed for their complete exposure the higher conceptions of religion and religious history which were originated by Lessing, Schleiermacher, and Hegel.

TINGHAE. See CHUSAN.

TINNÉ, ALEXANDRINE (1839–1869), African traveller, born at the Hague on 17th October, 1839, was the daughter of an English merchant and his wife, Baroness van Steengracht-Capellen. Her father died when she was five years old, leaving her the richest heiress in the Netherlands. After travelling in Norway, Italy, and the East, and visiting Egypt, when she ascended the Nile to near the equator, Mademoiselle Tinné left Europe again in 1861 for a prolonged sojourn in the Nile regions. Accompanied by her mother and her aunt, she set out from Cairo on 9th January, 1862. After a short stay at Khartoum, the party ascended the White Nile as far as Gondokoro and explored a part of the Sobat, returning to Khartoum in November. Baron von Heuglin and Dr. Steudner having meantime joined the ladies at Khartoum, the whole party set out in February, 1863, to explore the Bahr-el-Ghazal. The limit of navigation at the Bahr-el-Homr was reached on 10th March. From Lake Rek a journey was made overland, across the Bahr Jur and southwest by the Bahr Kosango, to Jebel Kosango, on the borders of the Niam-Niam country. During the journey all the travellers suffered severely. Steudner died in April and Madame Tinné in June, and after many fatigues and dangers the remainder of the party reached Khartoum in July, 1864. Mademoiselle Tinné returned to Cairo by Berber and Suakim. The geographical and scientific results of the expedition, largely into a new country, were highly important, as will be seen in Heuglin's narrative in *Petermann's Mittheilungen* (Erg.-hft, Nov. 15, 1865), and in his own *Travels in the Region of the White Nile* (1869). At Cairo Mademoiselle Tinné lived in somewhat Oriental style during the next four years, visiting Algeria, Tunis, and other parts of the Mediterranean. In January, 1869, she started from Tripolis with a caravan, intending to proceed to Lake Tchad, and thence by Wadai, Darfur, and Kordofan to the Upper Nile. In July, however, on the route from Murzuk to Rhat, she was murdered by her escort.

Besides the references already given, see John A. Tinné's *Geographical Notes of an Expedition in Central Africa by three Dutch Ladies*, Liverpool, 1864.

TINNEVELLI, or **TINAVELLY**, a district of British India in the Madras presidency, lying between 8° 9′ and 9° 56′ N. lat. and 77° 16′ and 78° 27′ E. long. It has an area of 5381 square miles, and a coast-line of nearly 100 miles. Madura district bounds it on the N. and N.E., on the S. and S.E. the Gulf of Mannár, and on the W. the southern Ghats. Tinnevelli is a large plain, with an average elevation of 200 feet, sloping to the east with slight undulations. Along the western boundary the mountains rise to 4000 feet; but they send out no spurs into the district, nor are there any isolated hills. The district is watered by numerous short streams, the principal being the Támbraparní (length 80 miles). In the north the scenery is unattractive and the soil poor; in the south red sandy soil prevails, in which little save the Palmyra palm will grow. But along the banks of the rivers are rice-fields and a variety of trees and crops. Many shoals occur near the shore, and in the northeast numerous rocks and reefs. The hills which divide Tinnevelli from Travancore are chiefly granite and gneiss; and along the coast stretches the broad belt of alluvium common to the whole east coast of India, and in it are many salt marshes, divided by sand-dunes from the sea. Several veins of calc spar cross the district from east to west, and the beds of all the rivers are more or less encrusted with a deposit of lime. The district contains many ancient and magnificent buildings; but the most interesting antiquities are the large sepulchral earthen urns of prehistoric races which have been found at several places, especially along the course of the Támbrapaní, and which contain bones, pottery of all sorts, beads and bronze ornaments, iron weapons, implements, etc. As the seat of Dravidian civilization Tinnevelli possesses more antiquarian interest than any other part of Madras. The climate is very hot and dry except at the season of the monsoons; the average annual rainfall throughout the district is less than 25 inches. Tinnevelli possesses several roads, but no canals. The South Indian Railway enters the district five miles north of Virudupatti and runs to Tuticorin (77 miles); a branch line (18 miles) connects this last town with Tinnevelli.

In 1881 the population numbered 1,699,747 (males 825,887, females 873,860), of whom 1,468,977 were Hindus, 89,767 Mohammedans, and 140,946 Christians. Tinnevelli has twelve towns with over 10,000 inhabitants each, viz., TINNEVELLI (see below); Srívilliputur, 18,256; Palamcotta, 17,964; Tuticorin, 16,281; Kulase Kharapatnam, 14,972; Sivagiri, 13,632; Víravanallur, 12,318; Rajapalayam, 12,021; Tenkási, 11,987; Káyalpatnam, 11,806; Kalladakúrchi, 10,936; and Sivakási, 10,833. Out of the total area of 5381 square miles 1403 are uncultivable waste. In 1885–86 cereals, chiefly rice and spiked millet, or *kambu*, the staple food of the district, occupied 842,741 acres, pulses 192,341, oil seeds 78,127, and cotton 206,717. The total area of forest is roughly estimated at 1500 square miles. Tuticorin is the only port of any importance. The chief exports are cotton, coffee, jaggery, chillies, etc.: sheep, horses, cattle, and poultry are also sent to Ceylon. There is a considerable inland trade with Travancore. The pearl fishery on the coast is now unimportant. Coastal navigation is dangerous. In 1885–86 the total revenue of the district was £365,744 [$1,777,515.84], of which the land-tax yielded £305,850 [$1,486,431].

The early history of Tinnevelli is mixed up with that of Madura and Travancore. Down to 1781 it is a confused tale of anarchy and bloodshed. In that year the nawab of Arcot assigned the revenues to the East India Company, whose officers then undertook the internal administration of affairs. Several risings subsequently took place, and in 1801 the whole Carnatic, including Tinnevelli was ceded to the British. Tinnevelli is now the most Christian district of all India, both Roman Catholic and Protestant.

TINNEVELLI, chief and largest town of the above district, is situated 1½ miles from the left bank of the Támbraparní in 80° 43′ 47″ N. lat. and 77° 43′ 49″ E. long. The town was rebuilt about 1560 by Visvanátha, the founder of the Nâyakkan dynasty of Madura, who erected many temples, etc., among them the great Siva temple. Tinnevelli is an active centre of Protestant missions in South India. In 1881 the population was 23,221 (10,963 males and 12,258 female

TINTORETTO. See ROBUSTI.

TIPPERAH, a district of British India, in the Chittagong division of the lieutenant-governorship of Bengal, situated between 23° 0′ and 24° 16′ N. lat. and 90° 36′ and 91° 39′ E. long., with an area of 2491 square miles. It is bounded on the N. by Maimansinh and Sylhet, on the S. by Noákálí, on the W. by the river Meghna, separating it from Maimansinh, Dacca, and Bákarganj, and on the E. by the state of Hill Tipperah. The district presents a continuous flat and open surface, with the exception of the isolated Lálmái range (100 feet), and is for the most part laid out in well cultivated fields, intersected in all directions by rivers and *khals* (creeks), which are partially affected by the tides. In the lowlands the soil is uniformly light and sandy; but in the higher parts a deep alluvial soil alternates with bands of clay and sand. The principal rivers are the Meghna, which is navigable throughout the year for boats of 4 tons burden, and the Gumti, Dákátiá, and Titás, which are also navigable for craft of 4 tons for a considerable portion of their course. There are many marshes or bhils. The principal road is the grand trunk (63 miles), which traverses the district from east to west. The wild animals include elephants, tigers, leopards, wild boars, jackals, and buffaloes. The climate is mild, agreeable, and healthy.

The population of the district in 1881 was 1,519,338 (males 770,893, females 748,445); of these Hindus numbered 511,025, Mohammedans 1,007,740, and Christians 199. There are only two towns with more than 10,000 inhabitants each viz., Comillah (13,372) and Bráhmánbária (17,438). Comillah is the chief town of the district and is situated on the south bank of the Gumti, in 23° 28′ N. lat. and 91° 14′ E. long. Rice is the staple crop of the district; wheat and barley, Indian corn and millet, pease, gram, and several other pulses are also cultivated, as well as betel-leaf and betel-nut, sugar-cane, tobacco, etc. The chief exports are rice, jute, and betel-nuts; and the principal imports, sugar, timber, cotton goods, cocoa-nut oil, bamboos, spices, salt, tobacco, etc. In 1885–86 the net revenue of the district amounted to £181,481 ($881,997.66), the land-tax contributing £102,866 ($499,928.76). Tipperah came under the East India Company in 1765; but more than a fifth of its present area was under the immediate rule of the raja of Hill Tipperah, who paid a tribute of ivory and elephants. At that time Tipperah formed part of Jalálpur; but in 1822 it was separated, and since then great changes have been made in its boundaries. With the exception of a serious raid in 1860 by the Kukis or Lusháis, nothing has disturbed the peace of the district.

TIPPERARY, an inland county of Ireland, in the province of Munster, is bounded N.W. by Galway, N.E. by King's county, E. by Queen's county and Kilkenny, S. by Waterford, and W. by Cork, Limerick, Clare, and Galway. Its greatest length north to south, from the confluence of the Little Brosna and the Shannon to the Knockmealdown Mountains is 70 miles, and its greatest breadth west and east 40. The area is 1,061,731 acres, or about 1659 square miles.

The surface is extremely varied and picturesque. The Knockmealdown Mountains on the southern border (2609 feet) are principally of clay slate formation. To the north of this range are the picturesque Galtees, composed of Silurian strata overlaid by Old Red Sandstone (Galtymore 3015 feet). To the east bordering Kilkenny, are the Slieveardagh Hills composed of coalstone shales and sandstones, and near Templemore the Devil's Bit Mountains, with a curious gap on the summit. In the northwest there is a Silurian and sandstone group (Keeper Hill 2265 feet). The greater part of the county is a gently undulating plain, belonging to the central Carboniferous limestone plain of Ireland. From the rich level country the rock of Cashel, also composed of limestone, rises with great boldness and abruptness. Tipperary has only one river, the Suir, which has its source in the Devil's Bit Mountains, and flows southwards by Templemore, Thurles, Cahar, and Clonmel. The Nore, which also rises in the Devil's Bit Mountains, soon passes into Queen's county, and the Shannon forms part of the western border. A spur of the Leinster coal-field, the most important in Ireland, runs into Tipperary, extending to Cashel, a distance of 20 miles with an average breadth of 5 miles. All the measures are represented. The productive portion of the field is at Killenaule. It consists of a narrow trough ranging in a northeast direction, the beds dipping towards the axis at a high angle. The coal is anthracite and the seams are thin, the workable portion being of limited extent. In the lower measures are marine fossils, and plant impressions are numerous. Copper is obtainable at Lackamore and at Hollyford near Thurles, but only in small quantities. There is a vein of lead at Shallee, and zinc has recently been dug in considerable quantities at Silvermines on the north side of the Keeper Mountains. Manganese, malachite, galena, and barytes are also obtainable. There are slate quarries at Killaloe. Between Caher and Clonmel are extensive deposits of fine pipe-clay. The Mitchelstown stalactite caverns, discovered accidentally in 1833, attract a large number of visitors.

Agriculture.—Tipperary ranks among the best agricultural districts of Ireland. The subsoil in the lower grounds is limestone, which is overlaid by a rich calcareous loam, capable of yielding the finest crops. The centre of the county is occupied by the Golden Vale, the most fertile district in Ireland, which stretches from Cashel to the town of Limerick. On the higher districts the soil is light and thin, partaking much of the character of the clay slate and sands on which it rests. Detached portions of the Bog of Allen encroach on the northeastern parts of the county. The total number of holdings in 1885 was 23,763 of which 14,369 were under 30 acres in extent,—4841 between 15 and 30 acres, 4444 between 5 and 15, 2861 between 1 and 5, and 2223 less than 1 acre. Of the total area 24.8 per cent. was under crops, including meadow and clover, 57.9 under grass, .1 fallow, 2.5 plantations, 4.9 bog and marsh, 6.4 barren mountain land, and 3.4 water, roads, fences, etc. The area under corn crops decreased from 85,883 acres in 1876 to 73,753 in 1885, the decrease having taken place since 1882, the areas in the previous years having been remarkably uniform. The area under wheat decreased from 13,423 acres in 1882 to 5474 in 1885, and that of oats from 57,332 to 50,196. But the area under barley, for which distillation causes a steady demand, rose from 13,551 acres in 1876 to 17,998 in 1885. The area under green crops manifests also a tendency to decrease; the total area in 1885 was 58,833 acres, 33,042 being under potatoes, 19,196 turnips, 2096 mangolds and beetroot, and 4499 other green crops. The area under meadow and clover has been steadily increasing, being 114,149 in 1876 and 127,478 in 1885. The total number of horses in 1885 was 27,365, of which 17,173 were used for agriculture; the number of cattle 254,488, of which 80,508 were milch cows, the manufacture of butter occupying considerable attention; of sheep 203,798, pigs 80,475, goats 13,011, and poultry 681,239. According to the latest landowners' *Return* (1876), the county was divided among 2372 proprietors owning 1,042,457 acres of an annual value of £676,683 ($3,288,679.38), the average value of the land being nearly 13s. ($3.16) per acre. The following possessed upwards of 10,000 acres each: Viscount Lismore, 34,945; Lord Dunalley, 21,081; G. K. S. M. Dawson, 19,093; Lady Margaret Charteris, 16,617; Marquis of Ormonde, 15,765; Viscount Hawarden, 15,272; N. Buckley, 13,260; earl of Clonmel, 11,098; and A. Moore, 10,200.

Manufactures.—A few persons are employed in mining, but the occupation of the inhabitants is chiefly agricultural. There are a considerable number of meal and flour mills.

Railways.—The county is remarkably well supplied with railways. A branch of the Great Southern and Western runs from Roscrea to Nenagh, where it joins a branch of the Limerick and Waterford, which in its progress southeastwards from Limerick crosses the southern corner of the county by Limerick Junction, Tipperary, Caher, and Clonmel. The main line of the Great Southern and Western to Cork and Killarney crosses the centre of the county by Templemore, Thurles, and Limerick Junction. A branch of the Limerick and Waterford connects Thurles with Clonmel.

Administration and Population.—Tipperary is divided into a north and south riding, each consisting of six baronies. For parliamentary purposes it is separated into four divisions—East, Mid, North, and South—each returning one member. It contains 193 parishes and 3253 town lands. It is in the Leinster circuit. Assizes for the north riding are held in Nenagh and for the south riding in Clonmel. Quarter sessions are held at Cashel, Clonmel, Nenagh, Roscrea, Thurles, and Tipperary. There are twenty-four petty sessions districts and parts of six others. The county is within the Cork military district. Ecclesiastically it belongs to the dioceses of Cashel, Emly, Killaloe, and Lismore. Since 1841 the population has decreased more than one-half. From 435,553 in that year it fell to 216,718 in 1871 and to 199,612 in 1881. The following towns in 1881 possessed over 4000 inhabitants each, viz., Clonmel (partly in Waterford), 9325; Tipperary, 7274; Carrick-on-Suir (partly in Waterford), 6583; Nenagh, 5422; and Thurles, 4850. The number of persons who could read and write was 115,185, who could read only, 24,386; the remainder—60,041—were unable to read or write. There were 248 persons who spoke Irish only and 23,558 able to speak Irish as well as English.

History and Antiquities.—Anciently Tipperary was included in the territory of the Tuatha Dé Danann, and afterwards probably of the clan of Degaid. Henry II., who landed at Waterford in October, 1172, received at Cashel the homage of Donald O'Brien, king of Thomond. It was made a county by King John in 1210; in 1328 Edward III. made it a county palatine in favor of the earl of Ormonde; and, though the king shortly afterwards resumed his regal prerogative, the county was regranted in 1337. In 1372 the grant was confirmed to James, second earl of Ormonde, the lands belonging to the church retaining, however, a separate jurisdiction,—a division which continued till the Restoration. In 1617 James I. took the county palatine into his own hands. It was, however, restored in 1661 to James, twelfth earl and first duke, whose regalities were further made to include the portions of the county formerly under ecclesiastical jurisdiction. On the attainder of James, second duke, in 1715 the jurisdiction reverted to the crown. There are two round towers within the county,—one at Roscrea and the other on the rock of Cashel. Of the old castles there are few important examples. That built by the first earl of Ormonde at Thurles has now disappeared. On the rock of Cashel there are a massive guard tower and some remains of the ancient wall. The stronghold of Caher, now occupied as a barrack, is still in good preservation. At Roscrea one of the towers of the castle built by King John still remains, and the stronghold of the Ormondes, erected in the reign of Henry VIII., forms the depôt attached to the barracks. The ecclesiastical ruins on the rock of Cashel are among the most remarkable in Ireland. They consist of a cathedral in the Pointed style of the 13th century, partly destroyed by fire in 1495; a curious Saxon chapel, ascribed to Cormac MacCullinan, archbishop of Cashel (b. 831); the bishop's palace; the "vicar's choral-house,"—all on the summit of the rock; and Hore abbey at its foot, founded for Benedictines in 1272. The abbey of Holy Cross was founded in 1182 for Cistercian monks, and is one of the finest monastic ruins in Ireland. The relic of the true cross, from which the abbey takes its name, is in possession of the Catholic hierarchy of the district. The other principal ecclesiastical ruins are the priory of Athassel, founded for Augustinian monks about 1200; Fethard abbey, founded in the 14th century, now used as a chapel; the gable and porch of the abbey of Roscrea, founded by St. Cronan in the 7th century; and a portion of the Franciscan friary founded in the same town in 1490.

TIPPERARY, a market town in the above county, is beautifully situated near the base of the Slieve-namuck or Tipperary Hills, a branch of the Galtee range, on the Waterford and Limerick Railway, 3 miles southeast of Limerick Junction and 110 southwest of Dublin. It contains a handsome Protestant church, a Catholic chapel, an endowed grammar-school, a townhall, and a new corn and butter market. Owing to its situation in the centre of a fine agricultural district, it enjoys considerable prosperity, and its butter market ranks next to that of Cork. The town is of great antiquity, but first acquired importance by the erection of a castle by King John, of which there are now no remains. A monastery founded for Augustinians by Henry III., which has also disappeared, gave a second impulse to its growth. Formerly it was a corporation from a grant made in 1310 by Edward II., but is now governed by commissioners under provision of the Town Improvement Act of 1854. The population in 1871 was 6638, and in 1881 it was 7274.

TIPPOO SAHIB (1749–1799), sultan of Mysore, was the son of HYDER ALI (*q.v.*), and was born in 1749. He received a careful Mohammedan education, and was instructed in military tactics by the French officers in the employment of his father. In 1767 in the invasion of the Carnatic he commanded a corps of cavalry, and he subsequently distinguished himself in the Mahratta War of 1775–79. On the outbreak of the first Mysore War in 1780 he was put at the head of a large body of troops, with which he achieved several successes; in particular he entirely defeated Brathwaite on the banks of the Colerun in February, 1782. He succeeded his father in December, 1782, and in 1784 concluded a treaty of peace with the English. In the same year he assumed the title of sultan. In 1787–88 he subjugated the Nairs of Malabar, and in 1789 provoked English invasion by ravaging the territories of the rajah of Travancore. When the English entered Mysore in 1790, he retaliated by a counter invasion, but he was ultimately compelled by Cornwallis's victory at Arikera, near Seringapatam, to purchase peace by the cession of the half of his dominions (16th March, 1792). The English having deemed it necessary to renew hostilities in March, 1799, he was in less than two months shut up in Seringapatam and accidentally killed during the siege (4th May, 1799.) See INDIA, vol. xii. pp. 842–3.

TIPTON, a town of England, in Staffordshire, is situated in the valley of the Stour, on the London and North-Western Railway, 4½ miles southeast of Wolverhampton and 121 northwest of London. It is built in a somewhat scattered and irregular manner, with coal-pits and iron and other works interspersed. Branches of the Birmingham Canal supply it with water communication. It depends chiefly on its iron manufactures, especially of a heavy kind, and has numerous large furnaces and rolling-mills. Its principal goods are rails, engine-boilers, tubes, fenders, and fire-irons. It also possesses works for making iron bridges and stations, cement-works, brick-works, and maltings. There are no public buildings of importance. Tipton has six churches. The parish church is of very ancient date, and its registers go back to the year 1513. Formerly the town was sometimes called Tibbington. It is under the government of a local board formed in 1866. The population of the urban sanitary district (area, 2697 acres) in 1871 was 29,445, and in 1881 it was 30,013.

TIRABOSCHI, GIROLAMO (1731–1794), the first historian of Italian literature, was born at Bergamo on 18th December, 1731. He studied at the Jesuit college at Monza, entered the order, and was appointed in 1755 professor of eloquence in the university of Milan. Here he produced (1766–68) *Vetera Humiliatorum Monumenta* (3 vols.), a history of the extinct order of the Umiliati, which gave him at once a distinguished place in literature. Nominated in 1770 librarian to Francis III., duke of Modena, he turned to account the copious materials there accumulated for the composition of his *Storia della Letteratura Italiana.* This vast work, in which the progress of Italian literature from the time of the Etruscans to the end of the 17th century is traced in detail, occupied eleven assiduous years, 1771–82, and the thirteen quarto volumes embodying it appeared successively at Modena during that period. A second enlarged edition (16 vols.) was issued from 1787 to 1794, and was succeeded by many others, besides abridgments in German, French, and English. Tiraboschi died at Modena on 3d June, 1794, leaving a high reputation for virtue, learning, and piety.

Tiraboschi wrote besides *Biblioteca Modenese* (6 vols., 1781–86); *Notizie de' Pittori, Scultori, Incisori, ed Architetti Modenesi*, (1786); *Memorie Storiche Modenesi* (5 vols. 1793–94); and many minor works. He edited the *Nuovo Giornale dei Letterati d' Italia* (1773–90), and left materials for a work of great research entitled *Dizionario Topografico-Storico degli Stati Estensi* (2 vols. 4to, Modena, 1824–25).

TIRESIAS, a famous Theban seer of Greek legend, was a son of Everes and Chariclo, and a descendant of Udæus, one of the men who had sprung up from the serpent's teeth sown by Cadmus. He was blind, for which various causes were alleged. Some said that the gods had blinded him because he had revealed to men what they ought not to know. Others said that Athene (or Artemis) blinded him because he had seen her naked; when his mother prayed Athene to restore his sight, the goddess instead purged his ears so that he could understand the speech of birds and gave him a staff wherewith to guide his steps. Another story was that on Mount Cyllene (or on Cythærum) he saw two snakes coupling; he killed the female and became himself a woman. Seven years afterwards he saw the same sight, and killing the male became himself a man again. When Zeus and Hera disputed whether more pleasure was enjoyed by the male or the female sex, they referred the question to Tiresias, as he had experience of both. He decided in favor of the female sex, and Hera in her anger blinded him; but Zeus gifted him with long life and infallible divination. He lived for seven or, according to others, nine generations. In the war of the Seven against Thebes he foretold to the Thebans that they would be victorious if Menœceus offered himself in sacrifice. In the war of the Epigoni he advised the Thebans to flee. They fled, and he with them; but coming to the Tilphusian well he drank of it and died. According to others, Tiresias was taken prisoner by the victorious Argives and died while they were taking him to Delphi. The Argives took his daughter Manto (or Daphne) prisoner and sent her to Apollo at Delphi, where, being as skilled a seer as her father, she gave oracles. A different version of the legend of Tiresias was given by the elegiac poet Sostratus (reported by Eustathius on *Od.*, x. 492). According to him, Tiresias was originally a girl, but had been changed into a boy by Apollo at the age of seven; after undergoing several more transformations from one sex to the other, she (for the final sex was feminine) was turned into a mouse and her lover Arachnus into a weasel. Tiresias's grave was at the Tilphusian spring; but there was a cenotaph of him at Thebes, where also in later times his "observatory," or place for watching for omens, was pointed out. He had an oracle at Orchomenus, but during a plague it became silent and remained so in Plutarch's time. According to Homer, Tiresias was the only person in the world of the dead whom Proserpine allowed to retain intelligence. He figured in the great paintings by Polygnotus in the Lesche at Delphi. The story of his transformation into a woman is perhaps to be explained by the custom of medicine-men dressing like women, which prevails in Borneo, Patagonia, Kadiak (off Alaska), and probably elsewhere.[1]

TIRHUT or TIRHOOT, a district of British India, was formerly the largest and most populous in Bengal. On 1st January, 1875, it was divided into the two districts of Darbhangah and Muzaffarpur. For the latter, see MUZAFFARPUR. The former with an area of 3335 square miles, lies between 25° 30′ and 26° 40′ N. lat. and 85° 34′ and 86° 46′ E. long., and is bounded on the N. by Nepal, on the E. by Bhágalpur, on the S. by Monghyr, and on the W. by Muzaffarpur. The population of Darbhangah in 1881 was 2,633,447 (males 1,295,788, females 1,337,659); of these Hindus numbered 2,323,979, Mohammedans 308,985, and Christians 325. Its chief towns are Darbhangah, the capital, with 65,955 inhabitants; Madhubani, 11,911; and Rusera, 11,578. The total revenue of Darbhangah district in 1885–86 amounted to £157,037 [$763,199.82], of which the land revenue yielded £80,442 [$390,948.12].

The alluvial tract of country formerly known as Tirhut is varied by undulations, with groves, orchards, and woods. The principal rivers are the Ganges, Gandak, Bághmati, Tiljugá, and Karái, which are rarely navigable, except during the rainy season, when they are mostly rapid and dangerous. Tirhut produces all sorts of crops, rice being the principal; others are wheat, barley, maize, oil-seeds, etc.; opium and tobacco are largely grown for export. The chief industries include the manufacture of indigo, saltpetre, coarse cloth, pottery, and mats. The Tirhut State Railway runs from Mokameh on the left bank of the Ganges through Darbhangah and Muzaffarpur districts northwest into Champaran district as far as Bettia. A ferry over the Ganges at Mokameh connects it with the East Indian Railway. There are two branches, one extending from Muzaffarpur southwest to Hajipur (to be connected with the Bengal and North-Western Railway at Sonapur by a bridge over the Gandak), the other (226 miles open for traffic in March, 1886) from Samastipur *via* Darbhangah to Janjarpur, from which it will extend eastwards to Partabganj, a mart upon the Kosi river near the Nepal frontier.

TIRLEMONT (Flem. *Thienen*), a town of Belgium, in the province of Brabant, 29½ miles by rail to the east of Brussels, on the Great Geete. The old walls, dismantled since 1804, are nearly 6 miles in circuit, but enclose a large extent of arable and garden ground. The streets are regular, and there are some spacious squares; the market-place contains the town-hall, recently restored, and the church of Notre Dame du Lac, founded in 1298, enlarged in the 15th century, but still unfinished. The church of St. Germain dates partly from the 9th century. The industries of the place include the making of steam-engines, brewing, distilling, soap-making, tanning, and various woollen and cotton manufactures. The population in 1876 was 13,296.

Tirlemont was once a much larger and more flourishing town than it now is; it has suffered much in war and was taken by the French in 1635, by Marlborough in 1705, and again by the French in 1793. John Boland the famous editor of the *Acta Sanctorum*, was born here in 1596.

TIRYNS, the Τίρυνς τειχιόεσσα of Homer (*Il.*, ii. 559), was a small Peloponnesian city, in the prehistoric period of the Achæan race, long before the Dorian immigration. It stood on a small rock in the marshy plain of Argolis, about 3 miles from the sea, and was fabled to have been founded by King Prœtus, the brother of Acrisius, who was succeeded by the hero Perseus. It was the scene of the early life of Heracles, who is hence called Tirynthius. The massive walls were said to have been the work of Cyclopean masons. Its period of greatest splendor was during the 11th and 10th centuries B.C., but the city continued to exist till about 468 B.C., when it was destroyed through the jealousy of the inhabitants of the neighboring Argos,[1] who had not assisted in the final defeat of the Persians at Platæa.[1]

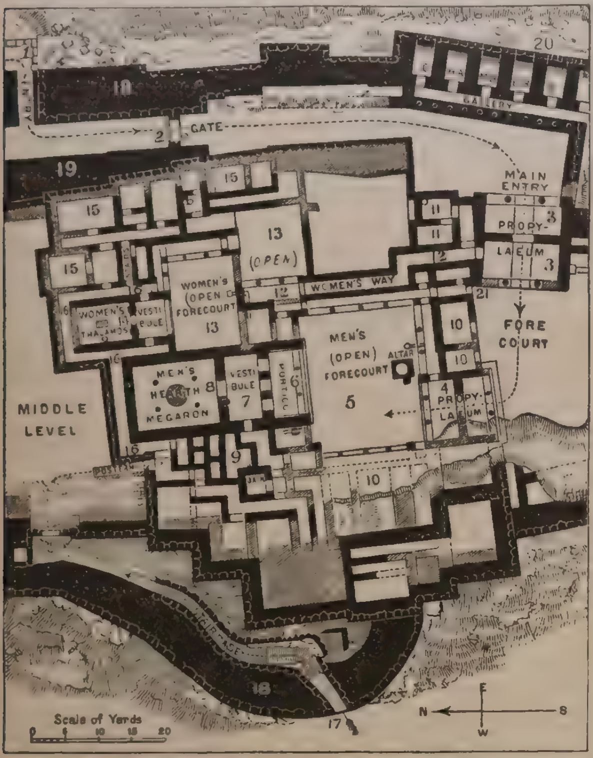

FIG. 1.—Plan of the palace in the upper part of Tiryns. 1. Main gate in the outer wall. 2. Inner gate, approached between massive walls. 3. Main propylæum. 4. Inner propylæum. 5. Court (αὐλή) of the men, surrounded by a colonnade on three sides; the altar to Zeus Herceus is by the entrance. 6. Αἴθουσα, portico of the men's megaron. 7. Πρόδομος, inner porch. 8. Men's megaron, with roof supported on four columns, and the circular hearth in the middle. 9. Bath-room and small θαλάμοι. 10, 10. Chambers round the great court. 11, 11. Guard chambers by the main propylæum. 12. Passage (λαύρη) from the main propylæum to the women's part. 13, 13. Courts of the women. 14. Women's megaron. 15. Chambers (θαλάμοι) in the women's part. 16. Passage from women's part to the rock-cut stairs. 17. Small postern door in the semicircular bastion, approached by flight of rock-cut steps. 18, 18. Massive outer wall of city. 19. Inner wall to guard the entrance passage. 20. Part of outer wall, with intermediate passage and rows of chambers, as shown in Fig. 2.

Excavations made in 1884–85 by Schliemann and Dörpfeld over part of the rock on which Tiryns stood have exposed a most interesting building, quite unique as an example of a Greek palace of the 11th or 10th century B.C., and of special interest from the way in which it closely illustrates the Homeric palaces of Alcinous and Odysseus, and throws a new light on scenes such as the slaughter of the suitors (*Od.*, xxi. and xxii.).

The rock on which Tiryns is built is of an irregular oval shape, about 330 yards long by 112 at the widest part, and is surrounded by a very massive wall, varying from 30 to 40 feet in thickness and averaging when complete about 50 feet in height, measuring from its base outside. Inside, the wall was probably not more than 10 or 12 feet high above the ground, so the masonry acts as a retaining wall to a considerable depth of earth which covers the rock (see Fig. 2 below). The wall is built of very large hammer-dressed blocks, some as much as 10 feet long by 3 feet 3 inches or 3 feet 6 inches wide, with smaller ones to fill up the interstices. The whole was bedded, not in mortar, but in clay, which has mostly been washed out of the joints; originally the surface was probably protected with a coating of stucco. The only important gateway, which was on the east side, away from the sea, probably resembled the "lion gate" at Mycenæ. The other entrances are mere slits in the wall. One of these and the chief gate are shown in Fig. 1. Internally the area of the city was divided by cross walls into three parts at successive levels. The lowest and middle divisions have not yet been excavated; the upper part at the south end of the rock was completely exposed in 1884–85 by Schliemann and Dörpfeld, and the almost complete plan of the various structures clearly made out. This division contains the palace of the ruler of Tiryns, a building which shows careful and skilful construction, elaborate decoration, and a well-arranged plan, suitable to the wants of a wealthy autocratic chief, who lived in a manner which partly recalls the luxury of an Oriental king, and also resembled the feudal state of a mediæval baron, surrounded by a crowd of vassals. From the main gate, which was defended by a tower, a strong passage led between the outer wall and an inner one to an inner gate, thence to a propylæum or double porch, with two wooden columns on each side,[3] adjoining which were chambers for guards. Then came another similar, but smaller propylæum, and opposite to that was the entrance of the great court (αὐλή), nearly 53 by 70 feet, in which stands the altar to Zeus Herceus, with a circular pit beneath it to catch the victims' blood. This court was surrounded by wooden columns supporting a roof, like a mediæval cloister; on the south side are chambers for attendants (θαλάμοι). On the north side is the great hall (μέλαρον[4]), with an outer portico supported by two columns (αἴθουσα) and an inner vestibule (πρόδομος) with three doors.[5] The hall is about 40 by 30 feet, with a circular hearth-stone in the centre (ἑστία or ἐσχάρα). Four columns supported the roof, the central part of which

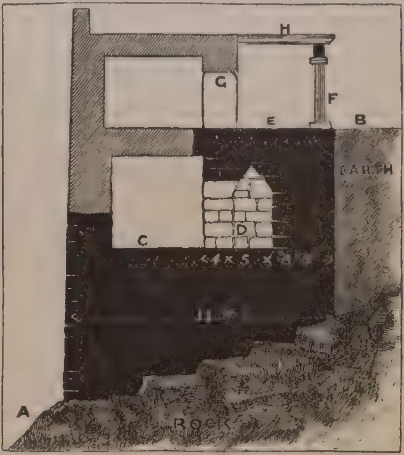

FIG. 2.—Section through the outer wall of the city at 20 in Fig. 1. A. Outer base of wall. B. Inside level of city. C. Intermediate platform for the garrison. D. Chambers opening on to it, with roof formed of projecting courses of stone in large blocks. E. Top of main wall, paved with clay, level with the inside. F. Wooden columns on existing stone bases, forming a porticus or covered walk along the top of the wall. G. Outer wall of the colonnade built of brick, now missing. H. Probable roof of the colonnade of wood, covered with beaten clay.

---

[1] Homer (*Il.*, ii. 559) speaks of the Tirynthians as subject to Argos.

[2] See Diod., iv. 10; Paus., ii. 25; and Herod., vi. 83, ix. 28. Schliemann (*Tiryns*, London, 1886) and Mahaffy (in *Hermathena*, Dublin), however, deny the truth of this statement, believing that Tiryns ceased to exist some centuries earlier, in spite of the strong evidence given by the inscription on the bronze column (now in Constantinople), formed by three twisted serpents, which once supported the golden tripod dedicated to Apollo out of the spoils from Platæa. Tiryns occurs in the list of allied states present at that battle; moreover, recent discoveries have brought to light remains of an important building of about 600 B.C.

[3] The arrows in Fig. 1 show the way from the city gate to the palace court and hall.

[4] The women's hall is also called the megaron; see *Od.*, xviii. 198.

[5] The πρόδομος is mentioned by Homer (*Il.*, ix. 473, and *Od.*, iv. 302); but in the palace of Odysseus the αἴθουσα seems to have been the only vestibule to the megaron. In several respects the palace of Tiryns is more magnificent than that of Odysseus, whose hall was paved with clay, not concrete as at Tiryns; see *Od.*, xxi. 122, where Telemachus ἀμφὶ δὲ γαῖαν ἔναξε, after cutting a trench to fix the row of axes.

probably rose above the rest like a mediæval "lantern"; and in this there was probably a door leading out to the flat roof round it—possibly the ὀρσοθύρη of Homer (*Od.*, xxii. 126), through which one of the suitors escaped and so got arms from the treasury or armory, which was on an upper floor (see *Od.*, xxii. 142 and xxi. 5). On the west side of the hall are a number of small chambers (θαλάμοι) for the unmarried men, and a bath-room about 12 by 10 feet, with its floor formed of one great slab of stone, sloped so as to drain out at one side through a pipe which passes through the wall. The women's part of the house is of equal importance to that of the men, and has its hall and two open courts with pillars. It is approached in a very circuitous way,[1] either by a passage (λαύρη) leading from a side door in the main propylæum or by another long passage which winds round the back of the men's hall, and so leads by a long flight of steps, cut in the rock, to the little postern door in the semicircular bastion. The many small rooms in this part of the palace were probably the bedrooms of the women and married couples of the chief's family. A staircase at 16 led to an upper floor, like the κλῖμαξ ὑψηλή of *Od.* xxi. 5. The circuit wall round the palace is more strongly constructed than the rest. On the south side it is built in two offsets, forming a level platform for the garrison halfway up. In the upper and thinner part of the wall two narrow passages at different levels are formed in its thickness. They are roofed by projecting courses of stone in large blocks. The wall on the east side has a similar intermediate platform, on to which open a series of small chambers formed in the mass of the upper wall (see Fig. 2). At the top level the wall was covered by a colonnade of wood pillars resting on circular stone blocks. This supported a flat roof and was open to the inside of the city. The back of the colonnade was built of brick, and is now missing, as are all the brick parts of the city, owing to the bricks having been only sun-dried.

The methods of construction employed in the Tiryns palace are of the highest interest. The foundations and about 3 feet of the walls above the ground are made of large blocks of stone bedded in clay; above this the wall was of brick, sun-dried, and covered with stucco. The upper story was probably of wood. Some of the thresholds of the doors were massive blocks of stone (λάϊνος οὐδός); others were of wood (δρύϊνος οὐδός). Wood was also used for all the columns, doorposts, and antæ (παραστάδες), and in some cases the walls of the rooms were lined with wood, carefully fixed by dowels, the holes for which still exist.[2] The doors had pivots of bronze revolving in well-fitted bronze cup-like sockets let into the thresholds. In the megaron and other rooms the floors are of good concrete, decorated with a simple series of incised lines, colored blue and red. The stucco of the internal wall is decorated with bold and very effective patterns—birds and scroll-work of semi-Oriental style; in many cases the motives are obviously taken from textile ornaments, as in the most archaic style of vase painting. One example of rich and costly decoration remains—part of a frieze of white alabaster, sculptured in relief with rosettes and interlacing patterns, and studded with jewel-like pieces of blue glass or enamel, the θριγκὸς κυάνοιο of *Od.* vii. 87.[3] Further excavations in the lower parts of the city will probably bring to light the dwellings of the citizens who garrisoned the place. The great bulk of the Tirynthians must have lived in houses outside the citadel, but under the shelter of its protection, just as in mediæval Italy villages grew up round the castles of any powerful lord.[4] (J. H. M.)

TISCHENDORF,[5] **LOBEGOTT FRIEDRICH KONSTANTIN** (1815–1874), an eminent Biblical critic, the son of a physician, was born on 18th January, 1815, at Lengenfeld, near Plauen, in the Saxon Voigtland. From the gymnasium at Plauen he passed in 1834 to the university of Leipsic, where he was mainly influenced by Winer, and began to take special interest in New Testament criticism. In 1840 he qualified as university lecturer in theology with a dissertation on the recensions of the New Testament text, the main part of which reappeared in the following year in the prolegomena to his first edition of the New Testament. The importance of these early textual studies was that they convinced him of the absolute necessity of new and exacter collations of MSS., and to this work he now gave himself. Above all he desired to go to Rome; but lack of help and money compelled him to turn first towards Paris, where he remained from October, 1840, till January, 1843, busy with the treasures of the great library, eking out his scanty means by making collations for other scholars, and producing for Didot several editions of the Greek New Testament, one of them exhibiting the form of the text corresponding most closely to the Vulgate. The great triumph of these laborious months was the decipherment of the palimpsest *Codex Ephraemi Rescriptus*, of which the New Testament part was printed before he left Paris and the Old Testament in 1845. His success in dealing with a MS. much of which had been illegible to earlier collators brought him into note and gained public and private support for more extended critical expeditions. From Paris he had paid short visits to Holland (1841) and England (1842). In 1843 he visted Italy, and after a stay of thirteen months went on to Egypt, Sinai, Palestine, and the Levant, returning by Vienna and Munich.[6] From Sinai he brought a great treasure, forty-three leaves of what is now known as the *Codex Sinaiticus* (ℵ). For the time he kept the place of discovery a secret, hoping to return and procure the rest of the book, and the fragments were published in 1846 as the *Codex Friderico-Augustanus*, a name given in honor of the king of Saxony. He now became professor in Leipsic and married (1845). His teaching was apparently not very remarkable; but his vacations were often occupied by fruitful critical journeys, and in 1853 and 1859 he made a second and a third voyage to the East. In the last of these, in which he had the active aid of the Russian Government, he at length got access to the remainder of the precious Sinaitic codex, and persuaded the monks to present it to the czar, at whose cost it was published in 1862. To gain for critical study a manuscript in point of age second only to the famous Vatican Bible was a splendid triumph, but Tischendorf's Eastern journeys were rich enough in other less sensational discoveries to deserve the highest praise.[7] Side by side with his industry in collecting and collating MSS., Tischendorf pursued a constant course of editorial labors, mainly on the New Testament, until he was broken down by overwork in 1873. He died on 7th December, 1874, at Leipsic.

The great edition, of which the text and apparatus appeared in 1869 and 1872,[8] was called by himself *editio viii.*; but this number is raised to twenty or twenty-one if mere reprints from stereotype plates and the minor editions of his great critical texts are included; posthumous prints bring up the total to forty-one. Four main recensions of Tischendorf's text may be distinguished, dating respectively from his editions of 1841, 1849, 1859 (*ed. vii.*), 1869–72 (*ed. viii.*). The edition of 1849 may be regarded as historically the most important from the mass of new critical material it used; that of 1859 is distinguished from Tischendorf's other editions by coming nearer to the received text; in the eighth edition the testimony of the Sinaitic MS. received great (probably too great) weight. The readings of the Vatican MS. were given with more exactness and certainty than had been possible in the earlier editions, and the editor had also the advantage of using the published labors of Tregelles. Whatever judgment may be passed on Tischendorf's critical tact and power, the apparatus of this final edition will not soon be superseded, and sums up a vast series of most important services to Biblical study.

Much less important was Tischendorf's work on the Greek Old Testament. His edition of the Roman text, with the variants of the Alexandrian MS., the Codex Ephraemi, and the Friderico-Augustanus, was of service when it appeared in 1850, but being stereotyped was not greatly improved in subsequent issues. Its imperfections, even within the limited field it covers, may be judged of by the aid of Nestle's appendix to the sixth issue (1880). Besides this may be mentioned editions of the New Testament Apocrypha (*Acts of Apostles*, 1851; *Gospels*, 1853, 2d ed. 1876; *Apocalypses*, 1866), and various minor writings, in part of an apologetic character, such as *Wann wurden unsere Evangelien verfasst?* (1865) and *Haben wir den echten Schrifttext der Evangelisten und Apostel?* (1873).

---

[1] The way to the harem in a modern Oriental house is similarly made as circuitous as possible for the sake of privacy.

[2] The marks of the wooden wall linings are specially clear in the little bath-room.

[3] The genuineness of this line has been questioned, but apparently without much reason.

[4] In modern Italian *castello* means a "village" as well as a "castle."

[5] In 1869 he became Konstantin von Tischendorf, having been raised to a place in the hereditary nobility of Russia.

[6] See his *Reise in den Orient*, Leipsic, 1845–46.

[7] The MSS. brought to Europe on the first two journeys are catalogued in the *Anecdota Sacra et Profana* (Leipsic, 1855, enlarged 1861). See also the *Monumenta Sacra Inedita* (Leipsic, 1846), and *Nova Collectio* of the same (1855–69). The third volume of the *Nova Coll.* gives the results of his last Eastern journey.

[8] The prolegomena remained unfinished at his death, and are being supplied by C. R. Gregory.

TISIO, or TISI, BENVENUTO (1481–1559), commonly called IL GAROFALO, a painter of the Ferrarese school. He was born in 1481 at Garofolo, in the Ferrarese territory, and constantly used the gillyflower (*garofalo*) as a symbol with which to sign his pictures. He took to drawing in childhood, and was put to study under Domenico Panetti (or Laneto), and afterwards at Cremona under his maternal uncle, Niccolò Soriani, a painter of credit, who died in 1499; he also frequented the school of Boccaccio Boccaccino. Removing to Rome, he stayed fifteen months with Giovanni Baldini, acquiring a solid style of draughtsmanship, and finally to Mantua, where he remained two years with Lorenzo Costa. He then entered the service of the marquis Francesco Gonzaga. Afterwards he went to Ferrara, and worked there four years, showing diligence and delicacy without much severity or elevation of style. Attracted by Raphael's fame, and invited by a Ferrarese gentleman, Geronimo Sagrato, he again removed to Rome, and found the great painter very amicable; here he stayed two years, rendering some assistance in the Vatican frescos. From Rome family affairs recalled him to Ferrara; there Duke Alphonso I. commissioned him to execute paintings, along with the Dossi, in the Villa di Belriguardo and in other palaces. Thus the style of Tisio partakes of the Lombard, the Roman, and the Venetian modes. He painted extensively in Ferrara, both in oil and in fresco, two of his principal works being the Massacre of the Innocents (1519), in the church of S. Francesco, and the Betrayal of Christ (1524), accounted his masterpiece. For the former he made clay models for study and a lay figure, and executed everything from nature. Both in the Ferrarese territory and in Rome his pictures of small dimensions are very numerous. He continued constantly at work until in 1550 blindness overtook him, —an affliction which he bore with patience, being a man of pleasant friendly disposition and of devout feeling. In the later years of his work he painted on all feast-days in monasteries for the love of God. He had married at the age of forty-eight and died at Ferrara on 6th (or 16th) September, 1559, leaving two children.

Garofalo combined sacred inventions with some very familiar details. A certain archaism of style, along with a strong glow of color, suffices to distinguish from the true method of Raphael even those pictures in which he most closely resembles the great master, and this is sometimes *very* closely. He was a friend of Giulio Romano, Giorgione, Titian, and Ariosto; in a picture of Paradise he painted this poet between St. Catherine and St. Sebastian. In youth he was fond of lute-playing and also of fencing. He ranks as the best of the Ferrarese painters; his leading pupil was Girolamo Carpi. The Adoration of the Magi, in the church of St. George near Ferrara, and a Peter Martyr, in the Dominican church, Ferrara (sometimes assumed to have been done in rivalry of Titian), are among his principal works not already mentioned. The Palazzo Chigi and the Palazzo Borghese contain numerous examples, and the London National Gallery four, one of them being a Madonna and Christ enthroned, with St. Francis and three other saints.

TITANIUM (atomic weight[1] = 48.08, O = 16), designates in chemistry a relatively rare element, which is customarily classed with the metals, although it comes nearer in its character to silicon than to any of the ordinary metals. Its discovery as an element was due to William Gregor, who found in the mineral menaccanite a new earth, which was regarded as the oxide of a new metal, menachin. Independently of him Klaproth in 1793 discovered a new metal in rutile and called it titanium; he subsequently found that it was identical with Gregor's element. The latter name was, however, retained. Titanium, although pretty widely diffused throughout the mineral kingdom, is not found in abundance. The commonest titanium mineral is rutile (TiO_2); anatase and brookite, though mineralogically different from rutile and each other, are forms of the same binoxide.

Metallic titanium is little known. In 1822 Wollaston examined a specimen of those beautiful copper-like crystals which are occasionally met with in iron-furnace slags, and declared them to be metallic titanium. This view had currency until 1849, when Wöhler showed that the crystals are a compound, $Ti(NC)_2 + 3Ti_3N_2$, of a cyanide and a nitride of the metal. Real titanium was made by Wöhler and Deville in 1857 by heating to redness fluo-titanate of potassium (see below) in vapor of sodium in an atmosphere of dry hydrogen, and extracting the alkaline fluoride formed by water. The metal thus produced had the appearance of iron as obtained by the reduction of its oxide in hydrogen. When heated in air, it burns brilliantly, with the formation of binoxide. Its most curious property is the readiness with which it unites with nitrogen gas into a nitride. The exact composition of this nitride is not known; but when heated in hydrogen it loses part of its nitrogen as ammonia, and becomes Ti_5N_6, a metallic-looking yellow solid, and this when heated in nitrogen gas passes into higher nitrides, which are again available for the production of ammonia. Tessié du Mothay in 1872 proposed to utilize these reactions for the production of ammonia from atmospheric nitrogen. Of other titanium compounds the most important are those formed on the type of TiX_4, when $X = Cl$, Br, or $\frac{1}{2}O$, etc.

The binoxide TiO_2 exists as rutile. One method of preparing a purer oxide from the mineral is to fuse it, very finely powdered, with six times its weight of bisulphate of potash in platinum, then extract the fuse with cold water, and boil the filtered solution for a long time. Titanic oxide separates out as a white hydrate, which, however, is generally contaminated with ferric hydrate and often with oxide of tin, SnO_2. A better method is Wöhler's. He fuses the finely powdered mineral with twice its weight of carbonate of potash in a platinum crucible, pounds the fuse, and treats it in a platinum basin with aqueous hydrofluoric acid. The alkaline titanate first produced is converted into crystalline fluo-titanate, TiF_6K_2, which is with difficulty soluble, and is extracted with hot water and filtered off. The filtrate, which may be collected in glass vessels if an excess of hydrofluoric acid has been avoided, deposits the greater part of the salt on cooling. The crystals are collected, washed, pressed, and recrystallized, whereby the impurities are easily removed. The pure salt is dissolved in hot water and decomposed with ammonia to produce a slightly ammoniacal hydrated oxide; this, when ignited in platinum, leaves pure TiO_2 in the form of brownish lumps, the specific gravity of which varies from 3.9 to 4.25, according to the temperature at which it was kept in igniting. The more intense the heat the denser the product. The oxide is fusible only in the oxy-hydrogen flame. It is insoluble in all acids, except in hot concentrated sulphuric, when finely powdered. Supposing the excess of vitriol to have been boiled away, the residue, after cooling, dissolves in cold water. The solution, if boiled, deposits its titanic oxide as a hydrate called meta-titanic acid, because it differs in its properties from ortho-titanic acid, obtained by decomposing a solution of the chloride in cold water with alkalies. The ortho-body dissolves in cold dilute acids; the meta-body does not. If titanic oxide is fused with excess of alkaline carbonate it expels CO_2 parts of carbonic acid for TiO_2 parts of itself. The salt R_2OTiO_2 is decomposed by water with the formation of a solution of alkali free of titanium, and a residue of an acid titanate, which is insoluble in water but soluble in cold aqueous mineral acids.

The chloride $TiCl_4$ is obtained as a distillate by heating to dull redness an intimate dry mixture of the binoxide and ignited lampblack in dry chlorine. The reaction may be carried out in a hard glass tube. For methods of purification we refer to the handbooks of chemistry. The pure chloride is a colorless liquid of 1.7604 specific gravity at 0° C. [32° F.], boiling at 136.4° [277.5] under 753.3 mm. pressure (T. E. Thorpe). It fumes strongly in moist air. When dropped very cautiously into cold water it dissolves into a clear solution, which, however, when boiled, deposits most of its oxide in the meta-hydrate form. There are, at least, two lower chlorides of titanium,—one of the composition Ti_2Cl_6 and another of the composition $TiCl_2$, both solids and both extremely prone to pass into titanic compounds. A solution of the tetrachloride in water, as well as of the soluble hydroxide in dilute acid generally, when kept in contact with metallic zinc, is reduced to one of the lower chlorides with development of a violet color. With regard to the detection of titanium we need not add much to what we have already given incidentally. Acid solutions of TiO_2 are not precipitated by sulphuretted hydrogen; but sulphide of ammonium acts on them as if it were ammonia, the H_2S being liberated. Oxide of titanium when fused with microcosmic salt (*i.e.*, $NaPO_3$) in the oxidizing flame yields a bead which is yellowish in the heat but colorless after cooling. In the reducing flame the bead becomes violet, more readily on the addition of tin; in the presence of iron it becomes blood-red. Titanic oxides when fused on charcoal, even with cyanide of potassium, yield no metal.

---

[1] According to T. E. Thorpe's researches, published in 1883.

TITANS, powerful beings of Greek mythology, the children of Sky and Earth. According to Hesiod, the male Titans were Oceanus, Cœus, Crius, Hyperion, Iapetus, and Cronus; the female were Thea, Rhea, Themis, Mnemosyne, Phœbe, and Tethys, to whom Apollodorus adds Dione. For the rebellion of the Titans against their father Sky (Uranus), the success and reign of Cronus, and the final consignment of the Titans to Tartarus by Zeus, see MYTHOLOGY, vol. xvii. p. 161, and SATURN, vol. xxi. p. 335 *sq.*

TITHES. It has been explained in SACRIFICE (vol. xxi. p. 147) that among ancient peoples sacrificial gifts frequently assume the character of a tribute in kind, paid to the deity in acknowledgment of the fruits of the land, or the increase of flocks attributed to his blessing. At first this tribute is not measured or enforced by law: the gift is a voluntary one, the magnitude of which may be fixed by a vow, or influenced by public opinion as to what is reasonable, but is not prescribed by any stated authority having power to exact what is prescribed. In the oldest Hebrew legislation sacrificial gifts to Jehovah (firstlings and first-fruits) are demanded; but apart from the consecration of the firstlings, which is imperative (Exod. xxii. 29 *sq.*, xxxiv. 19 *sq.*), the amount is not fixed. In Deuteronomy (xiv. 22 *sqq.*), on the other hand, the tithe or tenth of corn, wine, and oil is required in addition to the firstlings of the flock and the herd. This precept, written down in the 7th century B.C., is plainly no innovation, but rests on older usage (cp. Gen. xxviii. 22; Amos iv. 4); the new point emphasized is not that tithes must be paid, but that they must be consumed at the central, instead of a local, sanctuary (Deut. xii. 6, 11, xiv. 23 *sqq.*), apparently at the great autumn feast or Feast of TABERNACLES (*q.v.*).[1] Such a tithe is still nothing more than the old offering of first-fruits (*bikkūrīm*) made definite as regards quantity, and it was only natural that as time went on there should be some fixed standard of the due amount of the annual sacred tribute.[2] The establishment of such a standard does not necessarily imply that full payment was exacted; in Gen. xxviii. 22 Jacob vows of his own free will to pay tithes, just as the Arabs used to vow the tithe of the increase of the flock (schol. on Ḥárith *Moall.*, l. 69, ed. Arnold). The Arab did not always fulfil his vow, and there was no force to make him do so. But, however inexactly it may often have been paid, the proportion of one part in ten seems to have been accepted in many ancient nations as the normal measure of sacred tribute paid from the gains of husbandry, trade, or even of war.[3] The tithe, in fact, appears to have been a common form of tax upon the produce of land or other revenues, for civil as well as for sacred purposes. We find it in Greece (as at Athens), and in Sicily and Asia, under the Roman empire; but its special home was in the East. It was exacted on agricultural products and flocks by Hebrew kings (1 Sam. viii. 15, 17), and on imports by the monarchs of Babylon (Aristotle, *Œcon.*, ed. Berlin, p. 1352b). Aristotle gives the tithe on fruits of the soil the first place among the revenues of satraps (*Ibid.*, p. 1345b), and it still forms an important element in the fiscal system of Mohammedan states. It will be observed that the proportion of one in ten has been applied in the East, and in antiquity generally, to imports of very different kinds, and in Mohammedan taxation we find the name retained in cases where much less than a tenth is actually taken. In like manner Aristotle (*ut supra*) makes δεκάτη a mere synonym of ἐκφόριον, or tax on produce; the proportion of one to ten, it would seem, was so commonly taken in antiquity as the basis of *ad valorem* taxes that any such tax or tribute might be called a tithe. As regards the sacred tithe of the Hebrews, a distinction is drawn in Deuteronomy between the ordinary annual tithe, which may not have been a full tenth, and the "whole" or "full tithe," paid once in three years (Deut. xiv. 28, xxvi. 12), which the legislator directs to be stored at home, and spent in feeding the poor.

From Amos iv. 4 it is sometimes inferred that in the 8th century B.C. the sacrificial tithe, presented at a sanctuary, was triennial. But when the prophet, mocking the false zeal of the people, says, "Bring your sacrifices every morning and your tithes every three days" (not "years," as E. V.), he hardly implies more than that occasions of sacrifice were three times as frequent as tithe-day, and so alludes to the fact that there were by old usage three annual feasts and one annual tithe. A triennial sacrificial tithe is inconceivable when it is remembered that the tithe is only an extension of the first-fruits. The triennial tithe in Deuteronomy seems to be rather an innovation necessary in the interest of the poor, when sacrificial feasts were transferred to the central sanctuary, and ceased to benefit the neighbors of the offerer, who had a prescriptive claim to be considered on such occasions (comp. 1 Sam. xxv. 8 *sqq.*; Neh. viii. 10; Luke xiv. 13).

The priests of the sanctuaries had of old a share in the sacrificial feasts, and among those who are to share in the triennial tithe Deuteronomy includes the Levites, *i.e.*, the priests of the local sanctuaries who had lost their old perquisites by the centralization of worship. After the return, and before the work of Ezra, when Deuteronomy was still the law of the new Israel, but the Levites had become subordinate ministers of the temple, and required a more regular provision, the "whole tithe" was naturally fixed on for this purpose; but, instead of remaining in the hands of the tithe-payers to be doled out in charity, it was stored in the temple. Such, at least, was the plan proposed, though from Mal. iii. 8 *sqq.* it appears that it was very imperfectly carried out. As Malachi speaks in Deuteronomic phrase of the "whole tithe," the payment to the Levites was perhaps still only triennial; and, if even this was difficult to collect, we may be sure that the minor sacrificial tithe had very nearly disappeared. The indifference complained of in Mal. i. was in great part due to the fundamental changes in the religion of Israel, which made private altar gifts and feasts almost meaningless. On the other hand, the provision of regular support for the priests and Levites, the ministers of the public ritual, was now all important, and received special attention from Ezra and Nehemiah (Neh. x. 37 *sqq.*, xiii. 10 *sqq.*). They effected it by enforcing the new law of the priestly code (Num. xviii. 21 *sqq.*), in which it is formally laid down that the tithe is a tribute paid to the Levites, who in turn pay a tithe of it to the priests. The plain intention of the priestly code is to allow the old tithe of Deuteronomy to drop; but the harmonistic interpretation of the later scribes was to the effect that two tithes were to be paid every year, and a third tithe, for the poor, on every third year (Tob. i. 7 *sq.*; Jos.,

---

[1] Cp. Deut. xxvi. with 1 Sam. i. 21 (Sept.), and Jerome on Ezek. i. 3; and see Wellhausen, *Prolegomena*, p. 94 (Eng. tr., p. 92 *sq.*).

[2] In Deuteronomy, accordingly, the first-fruits (*bikkūrīm*) are not mentioned; the tithe takes their place. The word translated "first-fruits" in Deut. (*rêshîth*) is a small gift to the priests, a mere basketful (xviii. 4, xxvi. 2 *sq.*).

[3] For instances see Spencer, *De Legibus Hebræorum*, lib. iii., cap. 10, § 1. Among the Semites in particular note the tithe paid by the Carthaginians to the Tyrian Melkarth (Diod., xx. 14), and the tithe of frankincense paid in Arabia to the god Sabis (Pliny, *H.N.*, xii. 32; and comp. W. R. Smith, *Prophets of Israel*, p. 382 *sq.*). A tithe of cattle appears in Lydia (Nic. Damasc., fr. 24).

Ant., iv. 8, § 22). The last change in the system was the appropriation of the Levitical tithe by the priests, which apparently was effected by John Hyrcanus, though a tradition glaringly inconsistent with Nehemiah ascribes it to Ezra (*Mishnah*, "Ma'aser Sh.," v. 15; "Sota," ix. 10, and Wagenseil's note).[1]

(W. R. S.)

Tithes in Law.

Tithes were generally regarded up to the 17th century as existing *jure divino*, and as having been payable to the support of the church ever since the earliest days of Christianity. History, as Selden showed in his learned and exhaustive treatise (*History of Tithes*, 1618), does not bear out this view.[2] In the words of Hallam, "the slow and gradual manner in which parochial churches became independent appears to be of itself a sufficient answer to those who ascribe a great antiquity to the universal payment of tithes."[3] Long before the 8th century payment of tithes was enjoined by ecclesiastical writers and by councils of the church; but the earliest authentic example of anything like a law of the state enforcing payment appears to occur in the Capitularies of Charlemagne at the end of the 8th or beginning of the 9th century. Tithes were by that enactment to be applied to the maintenance of the bishop and clergy, the poor,[4] and the fabric of the church. In course of time the principle of payment of tithes was extended far beyond its original intention. Thus they became transferable to laymen and salable like ordinary property, in spite of the injunctions of the third Lateran council, and they became payable out of sources of income which were not originally tithable. The canon law contains numerous and minute provisions on the subject of tithes. The *Decretum* forbade their alienation to lay proprietors, denounced excommunication against those who refused to pay, and based the right of the church upon Scriptural precedents.[5] The Decretals contained provisions as to what was and what was not tithable property, as to those privileged from payment, as to sale or hypothecation to laymen, as to priority over state taxes, etc.[6] Various questions which arose later were settled by Boniface VIII.[7] The council of Trent enjoined due payment of tithes, and excommunicated those who withheld them.[8]

In England the earliest example of legal recognition of tithes is, according to Selden, a decree of a synod in 786.[9] Other examples before the Conquest occur in the *Fœdus Ælfredi et Guthruni* and the laws of Athelstan, Edgar, and Canute.[10] The tripartite division of tithes does not appear to have been recognized in England by any genuine legal enactment except as what Mr. Freeman calls "a counsel of perfection."[11] The earliest mention of tithes in statute law proper is in the Statute of Westminster the Second in 1285, c. 5 of which deals with the patron's writ *de advocatione decimarum*. From that date until the present year (1887) there have been a large number of Acts dealing with tithes,—the earliest which is still law being 2 Hen. IV. c. 4, making it an offence to purchase a bull from the pope for the discharge of land from tithes. The law has only attained its present condition by slow degrees, and by the combined effect of statutes and judicial decisions. The effect of the Tithe Commutation Act of 1836 has been to make most of the old law of merely historical interest, as in the course of the commutation all the questions of law as to prescription, exemptions, etc., would have been duly considered by the commissioners before the rent-charge was finally apportioned.

Tithes in English law are of three kinds,—predial, arising immediately from the soil, as of corn; mixed, arising from things nourished by the soil, as of milk or wool; personal, as of the profits of manual occupations or trades. The right to the last was considerably restricted by 2 and 3 Edw. VI. c. 13. They are also divided from other points of view into ordinary and extraordinary,—the latter being a tithe at a heavier rate charged on hop and market gardens,—and into great and small, as a rule those which go to the rector and vicar respectively. In general great tithes are predial, small are mixed and personal. It is not everything that is tithable; exemptions are claimable either from the nature of the property or the privilege of the owner. Stone, lime, and such other substances as are not of annual increase are exempt. So are creatures *feræ naturæ*. Exempt by privilege are the crown by its prerogative, and spiritual corporations in accordance with the maxim recognized equally by canon and common law, *ecclesia decimas non solvit ecclesiæ*. Thus a rector pays no tithes to his vicar, or a vicar to his rector. On the same principle it is a ground of exemption that lands were anciently the property of the privileged orders (at the time of the dissolution of monasteries, the Cistercians and Hospitallers), or were lands of the greater monasteries discharged from tithe by 31 Hen. VIII. c. 13. Exemption may also be claimed by redemption, by substitution of a rent-charge, by a real composition (that is, an agreement between the incumbent and the landowner, with the consent of the ordinary and patron, for the discharge from payment of tithe by means of satisfaction by giving of land or some other real recompense), by a *modus* (that is, a partial discharge owing to some customary method of tithing or *modus decimandi*), or by prescription under 2 and 3 Will. IV. c. 100. Tithes in extra-parochial places belonged at common law to the crown, except by custom. Tithes are incorporeal hereditaments (see REAL ESTATE), and may be dealt with like any other real estate of that nature. Thus they are, if in lay hands, tenements which may be entailed or leased, are subject to dower and curtesy, are assets for the payment of debts, and are (whether in lay hands or not) within the Statute of Limitations. They do not, however, issue out of the land like rents, but are collateral to it. Accordingly tithes are always freehold, even though they are charged on copyhold lands. Tithes are presumed to go to the parson of the parish. This presumption may be rebutted by proof that some or all the tithes go to the vicar, where the rector is in holy orders, or to a lay impropriator. It is said that about a third part of the tithes in England is in the hands of laymen. At one time arbitrary consecration of tithes was allowed,—that is, payment to any priest at the will of the tithe-payer. This was forbidden by a decretal epistle of Innocent III., about 1200. "This epistle decretall," says Coke, "bound not the subjects of this realm, but the same being just and reasonable they allowed the same, and so became *lex terræ*."[12] A vestige of the arbitrary consecration perhaps exists in the rarely occurring right of the parson of one parish to a portion of the tithes of another. Tithes are payable by all persons alike, whether members of the Church of England or not. Special enactments deal with their recovery from Roman Catholics and Quakers. Up to 1836 tithes were paid in kind, unless where any other method of payment applied in a particular case, such as a *modus* in the nature of a pecuniary compensation, or a pecuniary payment under the terms of a public or private Act, as in the city of London by 37 Hen. VIII. c. 12, 22 and 23 Car. II. c. 15, and other Acts. Even before 1836, however, the bulk of the tithes had been commuted, but such commutation was in ordinary cases good only during the tenure of a particular incumbency, and did not bind the incumbent's successors. The Act of 1836 merely completed and gave legislative sanction to a tendency which had been long on the increase.

The effect of the Tithe Commutation Act, 1836 (6 and 7 Will. IV. c. 71, frequently amended since), was to substitute for the tithe paid in kind or the fluctuating commuted tithe a rent-charge—commonly called the tithe rent-charge—equivalent to the market value from time to time on a septennial average of the exact quantities of wheat, barley, and oats which made up the legal tithes by the estimate in 1836. Excepted from the operation of the Act are (unless where there is a special provision approved by the commissioners) tithes of fish or of fishing, or any personal tithes other than those of mills, or any mineral tithes, or payments or rent-charges in lieu of tithes in London and other places, resting on the authority of local Acts. The Act has not been wholly successful in its working. By the transfer of estates, and by changes in local agriculture, the old estimates are no longer fairly applicable in all cases. The commutation has been, on the whole, to the advantage of the landowners, for the tithe remains fixed while the rental of land since 1836 has risen, according to Sir James Caird, from 33 millions to 52 millions [$160,380,000 to $252,720,000] per annum. Commutation under the Act is either by a voluntary agreement, confirmed by the tithe commissioners,[1] or by an award of the commissioners. The machinery for determining the tithe for any given year is as follows: the Board of Trade is to cause the average prices per imperial bushel of each sort of British corn to be computed from the summaries sent by the inspectors of corn returns, obtained from the averages stated by the inspectors, and published in the *London Gazette* weekly, quarterly, and yearly, and a septennial average is to be obtained from the sum of the annual averages divided by seven (45 and 46 Vict. c. 37, superseding sect. 56 of the Act of 1836). The rent-charge is computed on the basis of one-third for wheat, one-third for barley, and one-third for oats. The respective prices were originally fixed by 7 Will. IV. and 1 Vict. c. 69, s. 7 (as altered by the *London Gazette* of 9th December, 1837), at 7s. 1¼d. [\$1.72$\frac{6}{10}$] for wheat, 3s. 11½d. [96$\frac{3}{10}$c.] for barley, and 2s. 9d. [.67c.] for oats per bushel. The prices for 1887 were 4s. 11d. [\$1.19½], 3s. 10d. [93c.], and 2s. 7½d. [.63$\frac{8}{10}$c.] respectively. Owing to this fall in prices tithe rent-charge which stood at £100 [\$486] in 1836 was worth in 1887 only £87 8s. 10d. [\$424.97].

---

[1] A cattle tithe is demanded in Levit. xxvii. 32, and spoken of in 2 Chron. xxxi. 6. It is doubtful if this was ever acknowledged in practice. See Kuenen, *Godsdienst*, ii. 269 *sq.*, and Wellhausen, *op. cit.*, v. 1, § 2 (Eng. tr., p. 155 *sq.*), who argue that the passage in Leviticus is a later addition. The tendency of the Pharisees was to pay tithe on everything, and to make a self-righteous boast of this (Matt. xxiii. 23; Luke xviii. 12).

[2] It was his denial of the divine right of tithes that brought down the wrath of the Star Chamber upon the author. He was forced to retract an opinion too liberal for the time. See SELDEN.

After the coming into force of the Act of 1836 all lands were discharged from tithe, and the tithe rent-charge was substituted, payable by equal half-yearly payments, each 1st of July and 1st of January. A tenant paying the rent-charge is to be allowed the same in account with his landlord. The charge thus ultimately falls upon the landlord, whether or not he pays it in the first instance to the tithe-owner. Land may be given instead of a rent-charge where the tithe owner is an ecclesiastical person. Gardens or small tenements may be exempt from tithe by 3 and 4 Vict. c. 15. Later Acts give a power of redemption of rent-charge in the case of land required for public purposes, settled land, etc. (9 and 10 Vict. c. 73; 23 and 24 Vict. c. 93; 41 and 42 Vict. c. 42; 45 and 46 Vict. c. 38). Merger of the rent-charge is allowed by tenants in fee or in tail under the Act of 1836, and by persons having powers of appointment, tenants for life, and owners of glebes under 1 and 2 Vict. c. 64 and 2 and 3 Vict. c. 62. The mode of recovery of arrears provided by the Act of 1836 was a new one. Up to that time arrears could not be distrained for, unless in exceptional cases. The remedy of the parson was a suit for subtraction of tithes, which, by 2 and 3 Edw. VI. c. 13, could only be brought in a spiritual court. The remedy of the lay holder was a suit or action in any temporal court by 32 Hen. VIII. c. 7. It is provided by the Act of 1836 that, if the rent-charge be in arrear for twenty-one days, the person entitled to it may, after ten days' notice in writing, distrain upon the lands liable to the payment of it. If it be in arrear for forty days, and there be no sufficient distress on the premises, a writ of *habere facias possessionem* may issue, directing the sheriff to summon a jury to assess arrears. Not more than two years' arrears can be recovered by either means. It appears from these sections of the Act that the charge binds the land alone, and that there is no personal liability of either landlord or tenant. Though the charge is on the land, it is not on the inheritance, and it has been recently decided that arrears are not recoverable by sale of the lands out of which the rent-charge issues. The assessment of the rent-charge on wastes, common or Lammas lands, coppice wood, turnips, cattle agisted, etc. and the commutation of corn rents created by local Acts,, are the subject of special provisions. The Act of 1836 and later Acts provided for the division of the charge upon hop grounds, orchards, fruit plantations, and market gardens into the ordinary and extraordinary charge, the latter to be a rate per acre in addition to the ordinary charge. The extraordinary tithe applies only while the land is cultivated as a hop ground, etc., and in case of new cultivation comes into operation gradually, the full rate not being levied at once. The incident of the extraordinary tithe having been found an impediment to agriculture, especially in Kent, the Extraordinary Tithe Commutation Act, 1886 (49 and 50 Vict. c. 54), was passed as a remedy. It provides that no extraordinary tithe is to be charged upon any land newly cultivated after the passing of the Act. With regard to land subject at the passing of the Act to extraordinary tithe, the Act enables the land commissioners to certify the capital value of the extraordinary tithe on each farm or parcel of land, the land to be charged in lieu of the tithe with the payment of an annual rent-charge equal to 4 per cent on the capital value. The owner or any other person interested in the land may redeem the charge at its capital value. Tithe rent-charge is subject by the Act of 1836 to all parliamentary, parochial, and county rates, and is an hereditament within the Poor Rate Act of the same year (6 and 7 Will. IV. c. 96). The latter Act further enacts that in estimating the net annual value of ratable hereditaments, the rent is to be estimated free, *inter alia*, of tithe commutation rent-charge, if any.[2]

Scotland.—The terms "tithes" and "teinds" are both in use but the latter is the more common. Teinds are either drawn in kind, valued or redeemed. Originally they were all drawn in kind, as in England, but their commutation or redemption was the subject of many Acts of the Scottish parliament, especially those passed in 1633, the practical effect of which has been to make a fixed burden on the land take the place of a fluctuating payment, and to substitute a payment of one-fifth of the rent for one-tenth of the produce. In the first instance all teinds went to the church; but, when at the Reformation the crown became proprietor of the church lands, grants were made by it to the lords of erection or titulars of the tithes, laymen holding of the crown. The Act 1587, c. 29. annexed the church lands to the crown, with certain exceptions in favor of lay holders and others. All bishop's teinds and those formerly part of the revenue of the chapel royal are now crown property. The Church Patronage Act of 1874 does not affect the right to teinds of a patron or titular. Teinds in lay hands are subject to the burden of providing a suitable provision for the minister, the stipend being fixed by the Court of Teinds. All lands are subject to teinds except those which before the Reformation were feued *cum decimis inclusis et nunquam antea separatis*, so that the grantee held land and teinds together. In order to prove such an exemption, the person claiming under a *decimæ inclusæ* title must show that the lands and teinds belonged to a monastery, that the lands were never teindable, that they were *novalia*, or reclaimed by the monks themselves, that the title bears that the lands are held *cum decimis inclusis*, etc., and that it is previous to 1587. The judges of the Court of Session sit as commissioners of teinds,—a jurisdiction especially preserved by art. xix, of the Act of Union,—and exercise wider powers than any existing body in England, as they possess at once the jurisdiction of a court of justice and of the English land commissioners. The constitution and procedure of the Court of Teinds is regulated by 48 Geo. III. c. 138 and subsequent Acts.[3]

Ireland.—Many Acts of the Irish parliament deal with tithes, both generally and locally, the earliest being 33 Hen. VIII. c. 12, based upon the English Act, 28 Hen. VIII. c. 20. After the "tithe war" at the beginning of the 19th century, a tithe composition payable by the occupier was fixed by 4 Geo. IV. c. 99. In 1838 an annual rent-charge equal in amount to three-fourths of the tithe composition was substituted for the latter by 1 and 2 Vict. c. 109. The rent-charge is recoverable by distress where the person liable is the occupier, in other cases by action in the High Court of Justice, or by civil bill in claims under £20 [\$97.20]. The Irish Church Act, 1869 (32 and 33 Vict. c. 42), vests all tithe rent-charge then belonging to clergy of the Irish Church in the commissioners of church temporalities in Ireland. By that Act and the amending Act, 35 and 36 Vict. c. 90, the commissioners are enabled to purchase the surrender or assignment of any subsisting lease of tithe rent-charge made by an ecclesiastical person or corporation and to sell any rent-charge vested in them to the owner of the land charged therewith for a sum equal to twenty-two and a half years' purchase.[4] (J. W†.)

TITHONUS, a character of Greek mythology, a son or, according to others, a brother of Laomedon, king of Troy. He was beloved by Eos (the Morning), who carried him away and dwelt with him at the limit of the world, by the Ocean stream. Eos begged of Zeus that her lover might live forever, and her request was granted; but she forgot to ask immortal youth for him, so he shrivelled up into a hideous old man, whom Eos kept shut up in a chamber. At last Tithonus prayed to be rid of the burden of old age and was turned into a grasshopper. Eos had two sons by him—Memnon, king of Æthiopia, and Emathion. Memnon was killed before Troy by Achilles; but the legend is later than the *Iliad*, which does not mention it. As to Eos herself, her name is etymologically identical with the Sanskrit *ush* and the Latin *aurora*, both meaning "morning." According to Hesiod, Eos was a daughter of Hyperion and Thea, and sister of the Sun and Moon. Homer represents her arising every morning from the couch of Tithonus to carry light to gods and men, drawn in a chariot up the sky by her swift steeds Lampus and Phaethon. Her common epithet in Homer is "rosy-fingered," the meaning of which is disputed. Besides Tithonus she loved Orion till Artemis shot him with an arrow in Ortygia. She also loved and carried off the youthful hunter Cephalus; he was already married to Procris, to whom, in spite of his infidelity, he was afterwards reconciled. A peculiar form of the Cephalus legend is given by Apollodorus (iii. 14, 3): Cephalus, a son of Hermes and Herse, was carried off by Eos, and from their union in Syria sprang Phaethon. By Astræus, Eos became the mother of the Morning Star and all the starry host.

---

[1] By the Settled Land Act, 1882, the tithe commissioners have, with other bodies, been merged in the land commissioners constituted by the Act.

[4] [The Mormon Church in Utah exacts tithes but they are not required elsewhere in the United States. Tithes were abolished in France and other European countries at the time of the French revolution. By an old French law, still in force, tithes are collected in the Canadian province of Quebec.—AM. ED.]

With regard to representations in art, the combat between Achilles and Memnon was figured on the chest of Cypselus (Pausanias, v. 19, 1), and it appears on early Greek vases of Melos, Corinth, and Chalcis. There was a group of Eos carrying off Cephalus on the roof of the Stoa Basileios at Athens, and the same scene was represented on the throne at Amyclæ (Paus., i. 3, 1; iii. 18, 12). It also appears on vases, and formed an *acroterion* group on the temple at Delos. Eos in her chariot is represented on vases.

TITIAN (1477–1576). Tiziano Vecellio, or Vecelli, one of the greatest painters of the world, and in especial the typical representative of the Venetian school was commonly called during his lifetime "Da Cadore," from the place of his birth, and has also been designated "Il Divino." The country of Cadore, in the Friuli, barren and poor, is watered by the Piave torrent poured forth from the Carnic Alps, and is at no great distance from Tyrol. Titian, therefore, was not in any sense a Venetian of the lagoons and Adriatic, but was native to a country, and a range of association, perception, and observation, of a directly different kind. Venice conquered Friuli at a date not very remote from the birth of Titian; and Cadore, having to choose between Venetian and imperial allegiance, declared for the former. Approaching the castle of Cadore from the village Sotto Castello, one passes on the right a cottage of humble pretensions, inscribed as Titian's birth-place; the precise locality is named Arsenale. The near mountain—all this range of hills being of dolomite formation—is called Marmarolo. At the neighboring village of Valle was fought in Titian's lifetime the battle of Cadore, a Venetian victory which he recorded in a painting. In the 12th century the count of Camino became count also of Cadore. He was called Guecello; and this name descended in 1321 to the podestà (or mayor) of Cadore, to the stock to which the painter belonged. Titian, one of a family of four, and son of Gregorio Vecelli, a distinguished councillor and soldier, and of his wife Lucia, was born in 1477.

It used to be said that Titian, when a child, painted upon the wall of the Casa Sampieri, with flower-juice, a Madonna and Infant with a boy-angel; but modern connoisseurs say that the picture is a common work, of a date later than Titian's decease. He was still a child when sent by his parents to Venice, to an uncle's house. There he was placed under an art-teacher, who may perhaps have been Sebastiano Zuccato, a mosaicist and painter now forgotten. He next became a pupil of Gentile Bellini, whom he left after a while, because the master considered him too offhand in work. Here he had the opportunity of studying many fine antiques. His last instructor was Giovanni Bellini; but Titian was not altogether satisfied with his tutoring. The youth was a contemporary of Giorgione and Palma (Vecchio); when his period of pupilage expired, he is surmised to have entered into a sort of partnership with Giorgione. A fresco of Hercules on the Morosini Palace is said to have been one of his earliest works; others were the Virgin and Child, in the Vienna Belvedere, and the Visitation of Mary and Elizabeth (from the convent of S. Andrea), now in the Venetian academy. In 1507–8 Giorgione was commissioned by the state to execute frescos on the re-erected Fondaco de' Tedeschi. Titian and Morto da Feltre worked along with him, and some fragments of Titian's paintings, which are reputed to have surpassed Giorgione's, are still discernible. According to one account, Giorgione was nettled at this superiority, and denied Titian admittance to his house thenceforth. Stories of jealousies between painters are rife in all regions, and in none more than in the Venetian,—various statements of this kind applying to Titian himself. One should neither accept nor reject them uninquiringly; counter-evidence of some weight can be cited for Vecelli's vindication in relation to Moroni, Correggio, Lotto, and Coello. Towards 1511, after the cessation of the League of Cambrai—which had endeavored to shatter the power of the Venetian republic, and had at any rate succeeded in clipping the wings of the lion of St. Mark—Vecelli went to Padua, and painted in the Scuola di S. Antonio a series of frescos, which continue to be an object of high curiosity to the students of his genius, although they cannot be matched against his finest achievements in oil painting. Another fresco, dated 1523, is St. Christopher carrying the infant Christ, at the foot of the doge's steps in the ducal palace of Venice. From Padua Titian in 1512 returned to Venice; and in 1513 he obtained a broker's patent in the Fondaco de' Tedeschi, termed "La Sanseria" or "Senseria" (a privilege much coveted by rising or risen artists), and became superintendent of the Government works, being especially charged to complete the paintings left unfinished by Giovanni Bellini in the hall of the great council in the ducal palace. He set up an atelier on the Grand Canal, at S. Samuele,—the precise site being now unknown. It was not until 1516, upon the death of Bellini, that he came into actual enjoyment of his patent; at the same date an arrangement for painting was entered into with Titian alone, to the exclusion of other artists who had heretofore been associated with him. The patent yielded him a good annuity—120 crowns [$126.04]—and exempted him from certain taxes,—he being bound in return to paint likenesses of the successive doges of his time at the fixed price of eight crowns each. The actual number which he executed was five. Titian, it may be well to note as a landmark in this all but centenarian life of incessant artistic labor and productiveness, was now in the fortieth year of his age. The same year, 1516, witnessed his first journey to Ferrara. Two years later was produced, for the high altar of the church of the Frari, one of his most world renowned masterpieces, the Assumption of the Madonna, now in the Venetian academy. It excited a vast sensation, being indeed the most extraordinary piece of colorist execution on a great scale which Italy had yet seen. The signoria took note of the facts, and did not fail to observe that Titian was neglecting his work in the hall of the great council.

Vecelli was now at the height of his fame; and towards 1521, following the production of a figure of St. Sebastian for the papal legate in Brescia (a work of which there are numerous replicas), purchasers became extremely urgent for his productions. It may have been about 1523, after some irregular living and a consequent fever, that he married a lady of whom only the Christian name, Cecilia, has come down to us; her first child, Pomponio, was born in 1525, and two (or perhaps three) others followed. Towards 1526 he became acquainted, and soon exceedingly intimate, with Pietro Aretino, the literary bravo, of influence and audacity hitherto unexampled, who figures so strangely in the chronicles of the time. Titian sent a portrait of him to Gonzaga, duke of Mantua. A great affliction befell him in August, 1530, in the death of his wife. He then, with his three children—one of them being the infant Lavinia, whose birth had been fatal to the mother—removed to a new home, and got his sister Orsa to come from Cadore and take charge of the household. The mansion, difficult now to find, is in the Biri Grande, then a fashionable suburb, being in the extreme end of Venice on the sea, with beautiful gardens and a look-out towards Murano. In 1532 he painted in Bologna a portrait of the emperor Charles V., and was created a count palatine and knight of the Golden Spur, his children also being made nobles of the empire,—for a painter, honors of an unexampled kind.

The Venetian Government, dissatisfied at Titian's neglect of the work for the ducal palace, ordered him in 1538 to refund the money which he had received for time unemployed; and Pordenone, his formidable rival of recent years, was installed in his place. At the end of a year, however, Pordenone died; and Titian, who had meanwhile applied himself diligently to painting in the hall the battle of Cadore, was reinstated. This great picture, which was burned with several others in 1577, represented in life-size the moment at which the Venetian captain D'Alviano, fronted the enemy, with horses and men crashing down into the stream. Fontana's engraving, and a sketch by Titian himself in the gallery of the Uffizi in Florence, record the energetic composition. As a matter of professional and worldly success, his position from about this time may be regarded as higher than that of any other painter known to history, except Raphael, Michelangelo, and at a later date Rubens. In 1540 he received a pension from D'Avalos, Marquis del Vasto, and an annuity of 200 crowns [$210.06] (which was afterwards doubled) from Charles V. on the treasury of Milan. Another source of profit—for he was always sufficiently keen after money—was a contract, obtained in 1542, for supplying grain to Cadore, which he visited with regularity almost every year, and where he was both generous and influential. This reminds us of Shakespeare and his relations to his birthplace, Stratford-on-Avon; and indeed the great Venetian and the greater Englishman had something akin in the essentially *natural* tone of their inspiration and performance, and in the personal tendency of each to look after practical success and "the main chance" rather than to work out aspirations and pursue ideals. Titian had a favorite villa on the neighboring Manza Hill, from which (it may be inferred) he made his chief observations of landscape form and effect. The so-called Titian's mill, constantly discernible in his studies, is at Collontola, near Belluno. A visit was paid to Rome in 1546, when he obtained the freedom of the city, his immediate predecessor in that honor having been Michelangelo in 1537. He could at the same time have succeeded the painter Fra Sebastiano in his lucrative office of the piombo, and he made no scruple of becoming a friar for the purpose; but this project lapsed through his being summoned away from Venice in 1547 to paint Charles V. and others in Augsburg. He was there again in 1550, and executed the portrait of Philip II., which was sent to England and proved a potent auxiliary in the suit of the prince for the hand of Queen Mary. In the preceding year Vecelli had affianced his daughter Lavinia, the beautiful girl whom he loved deeply and painted various times, to Cornelio Sarcinelli of Serravalle; she had succeeded her aunt Orsa, now deceased, as the manager of the household, which, with the lordly income that Titian made by this time, was placed on a corresponding footing. The marriage took place in 1554. She died in childbirth in 1560. The years 1551 and 1552 were among those in which Titian worked least assiduously,—a circumstance which need excite no surprise in the case of a man aged about seventy-five. He was at the council of Trent towards 1555, of which his admirable picture or finished sketch in the Louvre bears record. He was never in Spain, notwithstanding the many statements which have been made in the affirmative. Titian's friend Aretino died suddenly in 1556, and another close intimate, the sculptor and architect Sansovino, in 1570. With his European fame, and many sources of wealth, Vecelli is the last man one would suppose to have been under the necessity of writing querulous and dunning letters for payment, especially when the defaulter addressed was lord of Spain and of the American Indies; yet he had constantly to complain that his pictures remained unpaid for and his pensions in arrear, and in the very year of his death (February) he recites the many pictures which he had sent within the preceding twenty years without receiving their price. In fact, there is ground for thinking that all his pensions and privileges, large as they were nominally, brought in but precarious returns. It has been pointed out that in the summer of 1566 (when he was elected into the Florentine academy) he made an official declaration of his income, and put down the various items apparently below their value, not naming at all his salary or pensions. Possibly there was but too much reason for the omission.

In September, 1565, Titian went to Cadore and designed the decorations for the church at Pieve, partly executed by his pupils. One of these is a Transfiguration, another an Annunciation (now in S. Salvatore, Venice), inscribed "Titianus fecit fecit," by way of protest (it is said) against the disparagement of some persons who cavilled at the veteran's failing handicraft. He continued to accept commissions to the last. He had selected as the place for his burial the chapel of the Crucifix in the church of the Frari; and, in return for a grave, he offered the Franciscans a picture of the Pietà, representing himself and his son Orazio before the Saviour, another figure in the composition being a sibyl. This work he nearly finished; but some differences arose regarding it, and he then settled to be interred in his native Pieve. Titian was ninety-nine years of age (more or less) when the plague,[1] which was then raging in Venice, seized him, and carried him off on 27th August, 1576. He was buried in the church of the Frari, as at first intended, and his Pietà was finished by Palma Giovane. He lies near his own famous painting, the Madonni di Casa Pesaro. No memorial marked his grave, until by Austrian command Canova executed the monument so well known to sightseers. Immediately after Titian's own death, his son and pictorial assistant Orazio died of the same epidemic. His sumptuous mansion was plundered during the plague by thieves, who prowled about, scarce controlled.

Titian was a man of correct features and handsome person, with an uncommon air of penetrating observation and self-possessed composure,—a Venetian presence worthy to pair with any of those "most potent, grave, and reverend signors" whom his pencil has transmitted to posterity. He was highly distinguished, courteous, and winning in society, personally unassuming, and a fine speaker, enjoying (as is said by Vasari, who saw him in the spring of 1566) health and prosperity unequalled. The numerous heads currently named Titian's Mistress might dispose us to regard the painter as a man of more than usually relaxed morals; the fact is, however, that these titles are mere fancy-names, and no inference one way or the other can be drawn from them. He gave splendid entertainments at times; and it is related that, when Henry III. of France passed through Venice on his way from Poland to take the French throne, he called on Titian with a train of nobles, and the painter presented him as a gift with all the pictures of which he inquired the price. He was not a man of universal genius or varied faculty and accomplishment, like Leonardo da Vinci and Michelangelo; his one great and supreme endowment was that of painting.

---

[1] Out of a total population of 190,000 there perished at this time 50,000.

Ever since Titian rose into celebrity the general verdict has been that he is the greatest of painters, considered technically. In the first place neither the method of fresco painting nor work of the colossal scale to which fresco painting ministers is here in question. Titian's province is that of oil painting, and of painting on a scale which, though often large and grand, is not colossal either in dimension or in inspiration. Titian may properly be regarded as the greatest manipulator of paint in relation to color, tone, luminosity, richness, texture, surface, and harmony, and with a view to the production of a pictorial whole conveying to the eye a true, dignified, and beautiful impression of its general subject-matter and of the objects of sense which form its constituent parts. In this sense Titian has never been deposed from his sovereignty in painting, nor can one forecast the time in which he will be deposed. For the complex of qualities which we sum up in the words color, handling, and general force and harmony of effect, he stands unmatched, although in particular items of forcible or impressive execution—not to speak of creative invention—some painters, one in one respect and another in another, may indisputably be preferred to him. He carried to its acme that great colorist conception of the Venetian school of which the first masterpieces are due to the two Bellini, to Carpaccio, and, with more fully developed suavity of manner, to Giorgione. Pre-eminent inventive power or sublimity of intellect he never evinced. Even in energy of action and more especially in majesty or affluence of composition the palm is not his; it is (so far as concerns the Venetian school) assignable to Tintoretto. Titian is a painter who by wondrous magic of genius and of art satisfies the eye, and through the eye the feelings,—sometimes the mind.

Titian's pictures abound with memories of his home-country and of the region which led from the hill-summits of Cadore to the queen-city of the Adriatic. He was almost the first painter to exhibit an appreciation of mountains, mainly those of a turreted type, exemplified in the Dolomites. Indeed he gave to landscape generally a new and original vitality, expressing the quality of the objects of nature and their control over the sentiments and imagination with a force that had never before been approached. The earliest Italian picture expressly designated as "landscape" was one which Vecelli sent in 1552 to Philip II. His productive faculty was immense, even when we allow for the abnormal length of his professional career. In Italy, England, and elsewhere more than a thousand pictures figure as Titian's; of these about 250 may be regarded as dubious or spurious. There are, for instance, 9 pictures in the London National Gallery, 18 in the Louvre, 16 in the Pitti, 18 in the Uffizi, 7 in the Naples museum, 8 in the Venetian academy (besides the series in the private meeting-hall), and 41 in the Madrid museum.

Naturally a good deal of attention has been given by artists, connoisseurs, and experts to probing the secret of how Titian managed to obtain such astonishing results in color and surface. The upshot of this research is but meagre; the secret seems to be not so much one of workmanship as of faculty. His figures were put in with the brush dipped in a brown solution, and then altered and worked up as his intention developed. The later pictures were touched off rapidly, telling well from a distant view. He himself averred, that after his visit to Rome in 1546 he had greatly improved in art; and, in his very last days he said—certainly with the modesty of genius, perhaps also with some of the tenacity of old age—that he was then beginning to understand what painting meant. In his earlier pictures the gamut of color rests mainly upon red and green, in the later ones upon deep yellow and blue. The pigments which he used were nothing unusual; indeed they were both few and common. Palma Giovane records that Vecelli would set pictures aside for months, and afterwards, examining them with a stern countenance as if they were his mortal enemies, would set to work upon them like a man possessed; also that he kept many pictures in progress at the same time, turning from one to the other, and that in his final operations he worked far more with finger than with brush. It has been said, and probably with truth, that he tried to emulate Palma Vecchio in softness as well as Giorgione in richness. Michelangelo's verdict after inspecting the picture of Danae in the Rain of Gold, executed in 1546, has often been quoted. He said, "That man would have had no equal if art had done as much for him as nature." He was thinking principally of severity and majesty of draughtsmanship, for he added, "Pity that in Venice they don't learn how to draw well." As a draughtsman of the human figure Titian was not only competent but good and fine, and he is reported to have studied anatomy deeply; but one can easily understand that he fell not a little short of the standard of Michelangelo, and even of other leading Florentines. He was wont to paint in a nude figure with Venetian red, supplemented by a little lake in the contour and towards the extremities. He observed that a colorist ought to manipulate white, black, and red, and that the carnations cannot be done in a first painting but by replicating various tints and mingling the colors. He distanced all predecessors in the study of color as applied to draperies,—working on the principle (in which Giorgione may perhaps have forestalled him) that red comes forward to the eye, yellow retains the rays of light, and blue assimilates to shadow. In his subject-pictures the figures are not very numerous, and the attitudes are mostly reserved; even in bacchanals or battles the athletic display has more of facility than of furor. His architectural scenes were sometimes executed by other persons, especially the Rosas of Brescia. The glow of late afternoon, or the passionate ardor of early sundown, was much affected by Titian in the lighting of his pictures. Generally it may be said that he took great pains in completing his works, and pains also in concealing the traces of labor. He appears to have had little liking for teaching, partly from distaste of the trouble, and partly (if we are to believe biographers) from jealousy. He was quite willing, however, to turn to some account the work of his scholars; it is related that on going out-of-doors he would leave his studio open, so that the pupils had a clandestine opportunity of copying his works, and if the copies proved of salable quality he would buy them cheap, touch them up, and resell them.

Titian's family relations appear to have been happy, except as regards his eldest son Pomponio. This youth, at the age of six, was launched upon the ecclesiastical career; but he proved wasteful and worthless, and Titian at last got so disgusted with him that he obtained the transfer to a nephew of a benefice destined for Pomponio. The fortune which he left was, after his decease, squandered by the tonsured prodigal. The other son, Orazio, born towards 1528, who (as we have seen) assisted Titian professionally, became a portrait-painter of mark,—some of his likenesses, almost comparable with Titian's own, being often confounded with his by owners and connoisseurs. He executed an important picture in the hall of the great council, destroyed by fire. He gave to alchemy some of the time which might have been bestowed upon painting. Several other artists of the Vecelli family followed in the wake of Titian. Francesco Vecelli, his elder brother, was introduced to painting by Titian (it is said at the age of twelve, but chronology will hardly admit of this), and painted in the church of S. Vito in Cadore a picture of the titular saint armed. This was a noteworthy performance of which Titian (the usual story) became jealous; so Francesco was diverted from painting to soldiering and afterwards to mercantile life. Marco Vecelli, called Marco di Tiziano, Titian's nephew, born in 1545, was constantly with the master in his old age, and learned his methods of work. He has left some able productions,—in the ducal palace, the Meeting of Charles V. and Clement VII. in 1529; in S. Giacomo di Rialto, an Annunciation; in SS. Giovanni e Paolo, Christ Fulminant. A son of Marco, named Tiziano (or Tizianello), painted early in the 17th century. From a different branch of the family came Fabrizio di Ettore, a painter who died in 1580. His brother Cesare, who also left some pictures, is well known by his book of engraved costumes, *Abiti Antichi e Moderni*. Tommaso Vecelli, also a painter, died in 1620. There was another relative, Girolamo Dante, who, being a scholar and assistant of Titian, was called Girolamo di Tiziano. Various pictures of his were touched up by the master and are difficult to distinguish from originals. Apart from members of his family, the scholars of Titian were not numerous; Paris Bordone and Bonifazio were the two of superior excellence. Domenico Teoscopoli (or Domenico Greco) was employed by the master to engrave from his works. It is said that Titian himself engraved on copper and on wood, but this may well be questioned.

We must now briefly advert to Titian's individual works, taking them in approximate order of time, and merely dividing portraits from other pictures. Details already given indicate that he did not exhibit any extreme precocity; the earliest works which we proceed to mention may date towards 1505. In the chapel of S. Rocco, Venice, is his Christ Carrying the Cross, now greatly dilapidated, which was an object of so much popular devotion as to produce offerings which formed the first funds for building the Scuola di S. Rocco; in the scuola itself is his Man of Sorrows. The singularly beautiful picture (see SCHOOLS OF PAINTING, vol. xxi. p. 467, Fig. 16) in the Borghese Palace in Rome, commonly named Divine and Human Love by some

Artless and Sated Love), bears some obvious relation to the style of Palma Vecchio. The story goes that Titian was enamored of Palma's daughter; but nothing distinct on this point is forthcoming. The Tribute Money (Christ and the Pharisee), now in the Dresden gallery, dates towards 1508; Titian is said to have painted this highly finished yet not "niggling" picture in order to prove to some Germans that the effect of detail could be produced without those extreme minutiæ which mark the style of Albert Dürer. The St. Mark in the church of the Salute—the evangelist enthroned, along with SS. Sebastian, Roch, Cosmo, and Damiano—a picture much in the style of Giorgione, belongs to 1512. Towards 1518 was painted, also in the same class of style, the Three Ages, now in Bridgewater House,—a woman guiding the fingers of a shepherd on a reed-pipe, two sleeping children, a cupid, an old man with two skulls, and a second shepherd in the distance,—one of the most poetically impressive among all Titian's works. Another work of approximate date was the Worship of Venus, in the Madrid museum, showing a statue of Venus, two nymphs, numerous cupids, hunting a hare, and other figures. Two of the London National Gallery pictures—the Holy Family and St. Catherine and the Noli Me Tangere—were going on at much the same time as the great Assumption of the Madonna. In 1521 Vecelli finished a painting which had long been due to Duke Alphonso of Ferrara, probably the Bacchanal, with Ariadne dozing over her wine-cup, which is now in Madrid. The famous Bacchus and Ariadne in the National Gallery was produced for the same patron, in 1523. The Flora of the Uffizi, the Venus of Darmstadt, and the lovely Venus Anadyomene of the Bridgewater Gallery may date a year or so earlier. Another work of 1523 is the stupendous Entombment of Christ in the Louvre, whose depth of color and of shadow stands as the pictorial equivalent of individual facial expression; the same composition, a less admirable work, appears in the Manfrini Gallery. The Louvre picture comes from the Gonzaga collection and from the gallery of Charles I. in Whitehall. In 1530 Titian completed the St. Peter Martyr for the church of SS. Giovanni e Paolo; for this work he bore off the prize in competition with Palma Vecchio and Pordenone. Of all his pictures this was the most daring in design of action, while it yielded to none in general power of workmanship and of feeling. It showed the influence of Michelangelo, who was in Venice while Vecelli was engaged upon it. A calamitous fire destroyed it in 1867; the copy of it which has taken its place is the handiwork of Cardi da Cigoli. To 1530 belongs also the Madonna del Coniglio (Louvre), painted for Gonzaga; to 1536 the Venus of Florence; to 1538 the portraits of the Twelve Cæsars, for Gonzaga; and to 1539 the Presentation of the Virgin in the Temple,—one of the conspicuous examples in the Venetian academy, yet not of the first interest or importance. About 1540 were done the forcible but rather uninspired paintings for S. Spirito, Venice, now in the church of the Salute—Cain Killing Abel, the Sacrifice of Abraham, and David and Goliath; in 1543 the Ecce Homo of the Vienna gallery, where Aretino figures as Pilate. The Venus and Cupid of Florence, the Venus of Madrid, and the Supper of Emmaus in the Louvre were still in hand, or just completed, when Titian was summoned to Augsburg in 1547. In 1554 he sent to Philip II. in England a second Danae and a Venus and Adonis. About the same time he sent to Charles V. a Trinity (or, as Titian himself termed it, Last Judgment), which represented the emperor, with his family and others, all in shrouds, praying to the Godhead; Moses and various other personages are also portrayed. This was the object upon which Charles continued to keep his eyes fixed until the film of death closed on them. Later pictures, from 1558 onwards, are the Martyrdom of St. Lawrence, Christ Crowned with Thorns (Louvre), Diana and Actæon, Diana and Callisto, Jupiter and Antiope, the Magdalene, Christ in the Garden, and Europa,—the last six for Philip II.; of the two Diana subjects there are duplicates in London and in Vienna. Philip, it will be observed, was equally *au fait* with nudities and with sanctities. The Jupiter and Antiope, now much restored, is commonly called La Vénus del Pardo, having at first been in the Pardo Palace. The Magdalene here spoken of (1561) seems to be the picture now in the Uffizi of Florence; Titian, in one of his letters, said that it was the most popular picture he had ever painted. In 1563 Vecelli offered to Philip II. his Last Supper, which had been in hand for six years; it was cut down in the Escorial to suit a particular space, and offers now little noticeable beyond the fine grouping. The St. Jerome of the Brera Gallery in Milan, a work of wonderful energy, spirit, and force, especially for a more than octogenarian hand, was probably rather earlier than this; there is a replica of it in the Escorial. One of the master's latest pictures (1574–75) is in Madrid, and commemorates the Battle of Lepanto; it is a work of failing power—but still the power of a Titian. Two of the mosaics in St. Mark's church, Venice,—the Mark in pontificals, and the sword-sheathing angel on the right of the high altar,—are after Vecelli's designs; but they are contrary to the true spirit of mosaic work, and the Mark in especial is a decided eyesore.

We now turn to the portraits,—works so great in style, so stately, and in the best sense so simple in perception and feeling that, after allowing everything which can be said on behalf of some other masters of the craft, such as Raphael, Velazquez, Rubens, and Rembrandt, one is still compelled to say that Titian stands on the whole supreme. Among the highest examples are—Alphonso, duke of Ferrara (Madrid); the same duke and his second wife Laura Dianti (Louvre), commonly called Titian and his Mistress; Francis I. (Louvre), painted towards 1536, but not from direct sittings, for Titian never saw the French king; various likenesses of himself, one of about 1542, and another of 1562; Paul III., also the same pope with his grandsons Cardinal Alessandro and Duke Ottavio (Naples),—the former, done in about four weeks, was presented to the pontiff in May, 1543, and cost two gold ducats [$4.54]; Pietro Aretino (Pitti); Titian's daughter Lavinia (with a fan in the Dresden gallery, with a jewelled casket in Lord Cowper's collection); the Cornaro Family (Alnwick Castle); L'Homme au Gant (Louvre), an unknown personage, youthful and handsome, the *ne plus ultra* of portraiture; Sansovino, Eleonora duchess of Urbino, Francesco duke of Urbino, Catherine Cornaro queen of Cyprus (these four are in the Uffizi); Charles V. on horseback (Madrid); Cardinal Bembo (Naples), discovered in an uncared-for condition in 1878, very unlike the portrait in the Barberini Gallery. The female portraits done by Titian are few, and are almost invariably of women of exalted rank. Of Ariosto, with whom Titian was intimate in Ferrara, though there may probably have been nothing approaching to a romantic friendship between them, the painter is said to have done three portraits. Much uncertainty, however, besets this matter. One of the three appears as a woodcut in an edition of the *Orlando Furioso*. A second, now at Cobham Hall, corresponds with the woodcut likeness, and is signed "Titianus F." The third, a work of admirable beauty, and a most fitting likeness of a poet, is in the National Gallery of London. It is difficult, however, to reconcile the features here with the other portraits, and some connoisseurs do not admit that the work is really a Titian.

Authorities.—For English readers, the *Life and Times of Titian* by Crowe and Cavalcaselle (1877) has superseded all previous works, such as those of Sir Abraham Hume (1829) and Northcote (1830). Mr. Josiah Gilbert's book, *Cadore, or Titian's Country* (1869), supplies many interesting side-lights on the subject. Mr. R. F. Heath's monograph (1885) is founded mainly on Crowe and Cavalcaselle and on Gilbert, and forms a very convenient compendium. In Italian, see the usual authorities—Ticozzi, Ridolfi, Lanzi, etc. (W. M. R.)

TITLES OF HONOR are words and phrases used for marking and distinguishing the rank or station of the persons to whom they are assigned and appropriated. Whatever may have been their actual or verbal origin, it is certain that among nations which have made any considerable progress in civilization their immediate derivation has been in the great majority of cases from some kind of public office or employment. As Mr. Freeman has pointed out,[1] the principal exceptions to this rule are the merely complimentary additions which it is usual to accord in Europe and America to persons who have no ascertained place or precedence in the social scale. Among ourselves "mister" or "master" (*magister*) and its feminine equivalents, and on the Continent *signor*, *señor*, and *sieur* (*senior*) and their feminine equivalents, are the leading examples. They are employed simply to avoid the necessity of calling those to whom they are applied by their proper names only, and are not indicative of any special rank or station. In France, however, *maître*, which answers to our mister or master, is the professional designation of an *avocat*, and in England "sir," which answers to *signor*, *senor*, and *sieur*, is the appropriate prefix to the Christian name and surname of a baronet or a knight. Of the derivatives of *dominus*—*don*, *donna*, and *dame*—the last in French compounded like *sieur* with the possessive pronoun in ordinary speech and appearing in *madame* as the feminine equivalent of *monsieur*, much the same may be said as of the derivatives of *magister* and *senior*. And, although our word "lord" has a special reference to the House of Lords, as the German *Herr* has to the *Herrenhaus* in certain of its uses, it largely partakes of the character which belongs to them. Its derivation is analogous to theirs, and within somewhat narrower limits it is almost as indiscriminately employed. More strictly lord and lady are the equivalents of baron and baroness, the fifth grade of the British peerage.[1] But colloquially it is applied to all grades of the peerage except the first; and, though duchesses are not called ladies in society, dukes are unquestionably lords in their capacity as members of the second chamber of the legislature. Certain of the sons and daughters of peers are lords and ladies by courtesy, while the wives of baronets are legally and the wives of knights are conventionally called ladies, although the wives of knights are more accurately described as dames. But besides this we have our lord the king and our lady the queen, lord bishops, lord lieutenants, lord justices, lord advocates, lord mayors, lord provosts, lords of the council, lords of the treasury, lords of the admiralty, lords of manors, and a variety of other lords who have no necessary connection with the nobility. Lord and lady in fact are among the titles of honor which have never been historically associated with any particular function. Lord was originally in Anglo-Saxon *hlâford*, probably a corruption of *hlâfweard*, "the warden of bread." Lady in Anglo-Saxon is *hlæfdige*, and has also some connection with *hláf*. Neither name acquired by means of official association any definite signification beyond the more or less general ascription of superiority.[2]

---

[1] In *Longman's Mag.*, vol. ii. p. 477 *sq.*

It is exceedingly difficult to distribute titles of honor into rigidly distinct categories. The following is as near an approximation as we are able to make.

I. *Supreme Sovereign Titles.*—Among titles implying sovereignty the first place is occupied by "emperor" and "king." Under existing international arrangements the crowned heads of Europe take precedence according to the date of their accession, and their rank is precisely the same, whether their style is imperial or royal. But the proper meaning of emperor is the chief of a confederation of states of which kings are members. The German emperor is an emperor in this sense, and he of course has precedence of the kings of Saxony, Bavaria, and Würtemberg, whose dominions are included in his empire. But neither he nor the emperors of Russia and Austria have any precedence as such of the queen of the United Kingdom or the kings of Italy and Spain. Originally the title of king was superior to that of emperor, and it was to avoid the assumption of the superior title of *rex* that the chief magistrates of Rome adopted the names of *Cæsar*, *imperator*, and *princeps* to signalize their authority. As *imperator* was the distinctive title of the ruler of the Western empire, so βασιλεύς was the distinctive title of the ruler of the Eastern empire, and the Greek βασιλεύς is the exact equivalent of the Latin *rex*. The emperor of the East was called αὐτοκράτωρ as well as βασιλεύς. But βασιλεύς came to mean the same as *imperator* in so special a way that the word ῥήξ was borrowed to express what had grown to be the inferior dignity of king.[3] Under Charlemagne the imperial style of Rome and the royal style of Germany were united.[4] It was, however, from Cæsar, which was common to the Western and the Eastern emperors alike, that the Teutonic word for emperor—*kaiser*—was derived. Until recent times, in fact, no sovereign thought of calling himself emperor unless he claimed in some way to represent the Roman Cæsars. Down to the beginning of the 19th century a German emperor who was not Roman emperor would have been an anomaly. At remote periods more than one of the West-Saxon kings called himself emperor of Britain, and more than one king of Castile called himself emperor of the Spains. But these assumptions appear to have been merely intended as protests against the assertion of superiority over them by the Roman emperors, German or Greek. Later on the kings of Portugal called themselves emperor of the Indies. But that title, like the queen of the United Kingdom's title of empress of India, was secondary only and did not affect their official designation in the hierarchy of European sovereigns.

The title of king does not suggest any of the questions which have been raised by that of emperor. "There is," as Mr. Freeman says, "a common idea of kingship which is at once recognized, however hard it may be to define it. This is shown among other things by the fact that no difficulty is ever felt as to translating the word king and the words which answer to it in other languages."[5] Etymologically indeed the Romance and Teutonic words for king have quite distinct origins. The Latin *rex* corresponds to the Sanskrit *rajah*, and meant originally steersman. The Teutonic king on the contrary corresponds to the Sanskrit *ganaka*, and "simply meant father, the father of a family, the king of his own kin, the father of a clan, the father of a people."[6] In English there is no feminine form of king like *königin*, the feminine form of *könig* in German. As the feminine equivalent of king, queen is used, which Prof. Max Müller says is "the old word for mother." He also cites the translation of the Bible by Ulfilas in the 4th century to prove its meaning at that early period as wife or woman. The queen was in fact in a special sense "the woman," or "the wife," the highest of women and the highest of wives in the kingdom.[7] King should properly describe the head of a nation in distinction from the head of a tribe, as emperor should properly describe the head of a confederation in distinction from the head of a nation. The idea of territorial sovereignty, of kingship over a land instead of over a people, grew up under the feudal system. In Britain it was unknown until long after the Norman Conquest. William the Conqueror, like Harold or Edward, was king of the English, and it was only from the reign of Henry II. that his successors were transformed into kings of England. The Eastern titles of sultan and shah are accepted as equivalent to those of emperor and king in the West. The sovereigns of China and Japan are called emperors both in common and in diplomatic parlance.

II. *Honorary Religious Titles of Sovereigns.*—The German emperors were formerly styled "defenders of the church," while the kings of France were called "very christian majesty" and "eldest sons of the church." The queen of England is "defender of the faith," the emperor of Austria as king of Hungary "apostolic majesty," the emperor of Russia as king of Poland "orthodox majesty," the king of Spain "catholic majesty," and the king of Portugal "very faithful majesty." All these titles were originally conferred by the popes. But the queen of the United Kingdom and the emperor of Austria alone employ them as part of their official description.

---

[1] "The baron alone among the ranks of peerage can hardly be called official, except so far as peerage itself is an office. His title rather marks a rank or class than an office; it does not at once point out even the memory of distinct functions like those of the duke, the marquis, or the earl" (*Longman's Mag.*, vol. ii. p. 483).

[2] Müller, *Lect. Sci. Lang.*, 2d ser., p. 255.

[3] Freeman, *Comparative Politics*, pp. 161–162.

[4] "The great triumph in the life of Charles the Great was when the ambassadors of the Eastern emperor Michael addressed him according to the full, imperial style (Eginhard, *Annals*, 812), 'Aquisgrani, ubi ad imperatorem venerunt . . . more suo, id est, Græca lingua, laudes ei dixerunt, *Imperatorem* eum et *Basileum* appellantes'" (Freeman, *Comparative Politics*, p. 253. Mr. Freeman notices also the great controversy concerning the imperial titles, especially the word βασιλεύς, which arose three generations later between the emperors Basil the Macedonian and Lewis the Second. See also John Lydus, *De Magistratibus*, 1, 3, on the distinction between τύραννος, βασιλεύς, and αὐτοκρατωρ, discussed in Freeman, *Comp. Pol.*, p. 445.

[5] Freeman, *Comp. Pol.*, p. 138.

[6] Max Müller, *Lect. Sci. Lang.*, 2d ser., p. 255. "All people, save those who fancy that the name *king* has something to do with a Tartar *khan* or with a "canning" or "cunning" man, are agreed that the English *cyning* and the Sanskrit *ganaka* both come from the same root, from that widely spread root whence comes our own *cyn* or kin and the Greek γένος. The only question is whether there is any connection between *cyning* and *ganaka* closer than that which is implied in their both coming from the same original root. That is to say, are we to suppose that *cyning* and *ganaka* are strictly the same word common to Sanskrit and Teutonic, or is it enough to think that *cyning* is an independent formation made after the Teutons had separated themselves from the common stock? . . . The difference between the two derivations is not very remote, as the *cyn* is the ruling idea in any case; but if we make the word immediately cognate with *ganaka* we bring in a notion about 'the father of his people' which has no place if we simply derive *cyning* from *cyn*" (Freeman, *Comp. Pol.*, pp. 450–451; see also his *Norm. Conq.*, vol. i. p. 583, and *Growth of the English Constitution*, p. 171).

[7] "The king's wife was called *regina* in Latin from the beginning; but there is no English word answering to *regina*: we have not and never had any word like the German *königin*. The queen is simply queen (*cwen*), woman, wife, the highest of wives in her husband's dominions. So the earl's wife was simply the earl's wife; the Norman style of countess now came in to fill up what was thought a defect. So with all strictly English titles, knight, sheriff, portreeve, alderman; they have no feminines; in most cases the wife does not share her husband's dignity. But the mayor, being a French title, has his mayoress, just as the duke has his duchess" (Freeman on "Titles," in *Longman's Magazine*, vol. ii. p. 489).

III. *Inferior Titles of Sovereignty.*—Grand-dukes rank next to kings. Grand-duke was the original title of the czars and was introduced into western Europe by Pope Pius V., who created Cosimo de' Medici grand-duke of Tuscany in the last half of the 16th century. There are now seven reigning grand-dukes in Germany. Prince and duke are titles also borne by the reigning chiefs of minor Germanic states. There are reigning princes of Monaco and Montenegro. The Eastern equivalents for these subordinate titles are khedive, emir, khan, and bey.

IV. *Titles of Nobility.*—The titles of the greater nobility are prince, duke, marquis, earl or count, viscount, and baron, and most of them exist in all European empires and kingdoms. In the United Kingdom there are no princes outside the royal family. In Russia there are no dukes except the imperial grand-dukes and neither marquises nor viscounts. In Germany there are no viscounts. Among the titles of the lesser nobility or gentry baronet and esquire are peculiar to the United Kingdom. Knight, chevalier, and ritter are recognized throughout Europe, and as far as Persia and Japan. Of old time in Scotland baron, now represented by laird, was not a title of the greater nobility, and the same may be said of *freiherr* in Germany. The peculiar designations of the chiefs of some of the Scottish clans and Irish septs, as The Chisholm, The O'Donoghue, Cameron of Lochiel, Macgillicuddy of the Reeks, and others must also be included among titles of honor. It would be improper to prefix "mister," or to affix "esquire," to their names in addressing them either orally or in writing, and their wives are always called madam. Pasha, bey, and effendi are the most familiar of the Eastern titles of nobility. The ecclesiastical titles of archbishop, bishop, dean, etc., and the military and naval titles of field-marshal, admiral, general, colonel, major, captain, etc., are common to all the countries of Europe, and are expressed by words in their several languages which are the precise equivalents of each other. But their incidentally dignified character is so overshadowed by their essentially administrative character that they can be regarded as titles of honor only in the same sense as the titles of officers of state or justice.

To the foregoing titles of honor may be added the large assortment of complimentary epithets which are attendant on them, and which are used as alternatively descriptive of the persons by whom they are borne. The Roman Cæsars were by decree of the senate called in Latin *augustus*, or sacred, which was rendered in Greek by σεβαστός, or adorable. They were also habitually styled *divi*, *pius* and *felix*, *clemens*, *tranquillus*, and *sanctissimus*. *Augustalis majestas* and ἁγία βασιλεία were among the styles of the Western and Eastern emperors respectively. Majesty, sacred majesty, or Cæsarean majesty, was the peculiar title of the emperors, and it was not assumed by any of the other sovereigns of Europe until comparatively modern times. But it is said to have been adopted in France as early as the reign of Louis XI.; in England the first king who used it was Henry VIII. Before that the kings of England had been called grace and highness, and sometimes excellent grace and kingly highness. All emperors are now imperial majesties, and all kings majesties, while grand-dukes, royal highnesses, and all inferior reigning potentates are highnesses of one sort or another. Imperial or royal highness is the proper title of the sons and daughters of emperors and kings, serene highness, or highness merely, being that of the members of princely families. The German *hoheit*, although it is commonly employed as the equivalent of highness or *altesse*, has a special signification of its own. It holds an intermediate rank between *altesse royal* or royal highness and *altesse sérénissime* or serene highness, unless it is qualified by the adjectives *kaiserliche* or *königliche*. For many years, however, it has been appropriated to the less important reigning and the mediatized princely houses, to distinguish them from the princely houses of new creation and the mediatized countly houses, to whom the titles of *durchlaucht* and *erlaucht* are severally assigned. In the United Kingdom grace is the title of dukes and duchesses, and lordship and ladyship of all other grades of the peerage and the bearers of courtesy titles of superior rank to any one of them. Dukes and duchesses are styled most noble, marquises and marchionesses most honorable, and all other peers and peeresses, lords and ladies by courtesy; privy councillors and the lord mayor of London are styled right honorable. Honorable is the title of the younger sons of earls, the sons and daughters of viscounts and barons, and the judges of the High Court of Justice. Archbishops are most reverend, bishops right reverend, deans very reverend, archdeacons venerable, and all clergymen reverend. The pope is his holiness, and cardinals are eminences. Viceroys, ambassadors, and governors are excellencies. But we have not yet rivalled the nice gradations in the descending scale of *illustres*, *spectabiles*, *clarissimi*, *perfectissimi*, and *egregii* which characterized the official or administrative hierarchy of the later Roman empire. (F. DR.)

TITMOUSE (Anglo-Saxon *Mase* and *Tytmase*, German *Meise*, Swedish *Mes*, Dutch *Mees*, French *Mésange*), the name[1] long in use for several species of small English birds, which are further distinguished from one another by some characteristic appellation. These go to make up the genus *Parus* of Linnæus, and with a very uncertain number of other genera form the Family *Paridæ* of modern ornithology. Its limits are, however, very ill-defined; and here only the species best known to English readers can be noticed.

The first to be mentioned is that called from its comparatively large size the Great Titmouse, *P. major*, but known also in many parts as the Oxeye,[2] conspicuous by its black head, white cheeks, and yellow breast, down which runs a black line, while in spring the cock makes himself heard by a loud love-note that resembles the noise made in sharpening a saw. It is widely distributed throughout the British Islands, and over nearly the whole of Europe and northern Asia. The next is the Blue Titmouse, Blue-Cap, or Nun, *P. cæruleus*, smaller than the last and more common. Its names are so characteristic as to make any description needless. A third common species, but not so numerous as either of the foregoing, is the Coal-Titmouse, *P. ater*, distinguished by its black cap, white cheeks, and white nape. Some interest attaches to this species because of the difference observable between the race inhabiting the scanty remnants of the ancient Scottish forests and that which occurs throughout the rest of Britain. The former is more brightly tinted than the latter, having a clear bluish gray mantle and the lower part of the back greenish, hardly either of which colors are to to be seen in the same parts of more southern examples, which last have been described as forming a distinct species, *P. britannicus*. But it is to be observed that the denizens of the old Scotch fir-woods are nearly midway in coloration between the dingy southern birds and those which prevail over the greater part of the Continent. It would therefore seem unreasonable to speak of two species only: there should be either three or one, and the latter alternative is to be preferred, provided the existence of the local races be duly recognized. Much the same thing is to be noticed in the next species to be mentioned, the Marsh-Titmouse, *P. palustris*, which, sombre as is its plumage, is subject to considerable local variation in its very extensive range, and has been called *P. borealis* in Scandinavia, *P. alpestris* in the Alps, and *P. lugubris* in south-eastern Europe, to say nothing of forms like *P. baicalensis*, *P. camchatkensis*, and others, whose names denote its local variations in northern Asia, while no great violence is exercised if to these be tacked on *P. atricapilla* with several geographical races which inhabit North America. A fifth British species is the rare Crested Titmouse, *P. cristatus*, only found in limited districts in Scotland, though common enough, especially in pine-woods, in many parts of Europe.

It is impossible to state how many species of *Parus* exist, their recognition at present being wholly subjective to the view taken by the investigator of the group. Its latest monographer is Dr. Gadow (*Cat. B. Br. Museum*, viii. pp. 3–53), who recognizes forty-eight, besides several sub-species. North-American ornithologists include some fifteen as inhabitants of Canada and the United States; but scarcely two writers agree on this point, owing to the existence of so many local forms. Of the species inhabiting the Indian and Ethiopian Regions there is no space here to treat, and for the same reason the presumably allied forms of Australia and New Zealand must be left unnoticed. During the greater part of the year the various species of the genus *Parus* associate in family parties in a way that has been already described (BIRDS, vol. iii., p. 664), and only break up into pairs at the beginning of the breeding-season. The nests are nearly always placed in a hollow stump, and consist of a mass of moss, feathers, and hair, the last being worked almost into a kind of felt. Thereon the eggs, often to the number of eight or nine, are laid, and these have a translucent white shell, freckled or spotted with rust-color. The first plumage of the young closely resembles that of the parents; but so far as is known, it has always a yellower tinge, very apparent on the parts, if there be such which in the adult are white. Few birds are more restless in disposition, and if "irritability" be the test of high organization as a much bepraised systematist asserts, the *Paridæ* should stand very near the top of the list. Most of the European species and some of the North-American become familiar, haunting the neighborhood of houses, especially in winter, and readily availing themselves of such scraps of food, about the nature of which they are not particular, as they can get.[1] By gardeners every Titmouse is generally regarded as an enemy, for it is supposed to do infinite damage to the buds of fruit trees and bushes; but the accusation is wholly false, for the buds destroyed are always found to be those to which a grub—the bird's real object—has got access, so that there can be little doubt that the Titmouse is a great benefactor to the horticulturist, and hardly ever more so than when the careless spectator of its deeds is supposing it to be bent on mischief.

---

[1] The prefix "Tit," by heedless writers often used alone, though equally proper to the Titlark (cf. PIPIT, vol. xix. p. 121), is perhaps cognate with the Greek τιτίς, which originally meant a small chirping bird (*Ann. Nat. History*, ser. 4, x. p. 227), and has a diminutive form in the Icelandic *Tittlingur*—the English or at least Scottish *Titling*. It is by false analogy that the plural of Titmouse is made *Titmice*; it should be *Titmouses*. A nickname is very often added, as with many other familiar English birds, and in this case it is "Tom."

[2] The signification of this name is obscure. It may perhaps be correlated with a Swedish name for the bird—*Talgoxe*.

Akin to the genus *Parus*, but in many respects differing from it, is *Acredula*, containing that curious-looking bird the Long-tailed or Bottle-Titmouse, with its many local races or species, which must be here passed over without a word. The bird itself, having its tail longer than its body, is unlike any other found in the northern hemisphere, while its nest is a perfect marvel of construction, being in shape nearly oval with a small hole in one side. The exterior is studded with pieces of lichen, worked into a firm texture of moss, wool, and spiders' nests, and the inside is profusely lined with soft feathers—2379 having been, says Macgillvray, counted in one example. Not inferior in beauty or ingenuity is the nest built by the Penduline Titmouse *Ægithalus pendulinus*, of the south of Europe, which differs, however, not merely in composition but in being suspended to a bough, while the former is nearly always placed between two or more branches.

The so-called Bearded Titmouse, *Panurus biarmicus*, has habits wholly unlike those of any of the foregoing, and certainly does not belong to the family *Paridæ*, though its real affinity has not yet been clearly shown. It was formerly found in many parts of England, especially in the eastern counties, where it bore the name of Reed-Pheasant;[2] but through the draining of meres, the destruction of reed-beds, and (it must be added) the rapacity of collectors it now only exists as a native in a very few localities. It is a beautiful little bird of a bright tawny color, variegated with black and white, while the cock is further distinguished by a bluish gray head and a black tuft of feathers on each side of the chin. Its chief food seems to be the smaller kinds of freshwater mollusks, which it finds among the reed-beds it seldom quits.

The general affinities of the *Paridæ* seem to lie rather with the *Sittidæ* (*cf.* NUTHATCH, vol. xvii. p. 684) and the Tree-Creepers; and those systematists who would ally them to the *Laniidæ* (SHRIKE, vol. xxi. p. 885), or still more interpose the last between the former Families, have yet to find grounds for so doing. (A. N.)

TITUS. By this, his Roman prænomen, is usually known the eleventh of the Twelve Cæsars, TITUS FLAVIUS SABINUS VESPASIANUS, emperor from 79 to 81 A.D. With his father Vespasian, who rose to empire from the camp, began the Flavian line of emperors, the last three Cæsars. Titus was born in 40, the year of the assassination of the fourth Cæsar, Caius Caligula, and was brought up in the household of Claudius, with that emperor's son, Britannicus. There was a story that he was dining at Nero's table when Britannicus was poisoned, and that he himself tasted the fatal cup, and had in consequence a serious illness. Some time afterwards he erected two statues to the young prince's memory. Educated in the imperial court, he was thoroughly trained in all elegant accomplishments: he could speak Greek fluently, and could compose verses; he was a proficient in music; he could write shorthand, and could imitate handwriting so skilfully that he used to say that he might have been a most successful forger. He was very handsome, with a fine commanding expression, and a vigorous frame, well trained in all the exercises of a soldier. As a young man he served with credit in Germany and in Britain, and he practiced at the bar. Soon he had the command of a legion, and joined his father in Syria; he took an active part in the Jewish War, capturing several important fortresses, among them Tarichææ and Gamala. In 68 he went at his father's bidding on a visit of congratulation to the newly proclaimed emperor, Galba; but, hearing of Galba's death and of the general confusion in the Roman world, he returned to his father in Palestine, having in the meantime consulted the oracle of the Paphian Venus as to his prospects and received a favorable answer. In the following year Vespasian, who, through his son's pleasing manner and adroit management, had made a friend of Mucianus, the governor of Syria, became emperor, and left Titus to finally settle the Jewish war by the capture of Jerusalem. Titus conducted the siege of the city, which for some months was defended amid incredible horrors, with signal ability, and took and destroyed it in September, 70. The army saluted their victorious general by the title of "imperator"; in the East Titus was now supreme, and practically emperor. On his return to Italy by way of Alexandria he fell in with that strange professor of mystical philosophy and magic, Apollonius of Tyana, and listened, it is said, to his pedantic talk and advice. As soon as he arrived at Rome there was the usual triumph for a decisive victory, and both father and son shared it. On the arch of Titus, as it is called, erected some few years afterwards (see vol. xx. p. 851), may still be seen sculptured representations of Jewish captives and of the captured trophies. Titus was now formally associated with his father in the government, with the title of Cæsar, and during the nine remaining years of Vespasian's reign he controlled the administration, and was in fact emperor. He was anything but popular; he had the character of being luxurious, self-indulgent, profligate, and cruel. Summary execution of obnoxious persons seems to have been not uncommon. There was a bad scandal too about his connection with the shameless Jewish beauty Berenice, the sister of the Agrippa of the Acts of the Apostles; both brother and sister followed Titus to Rome, and were allowed to reside in the imperial palace. Public opinion at Rome was outraged, and Titus, though he had promised Berenice marriage, felt obliged to send her back to the East. Vespasian died in 79, leaving his son a safe throne and a well-filled treasury. The forebodings of the people were agreeably disappointed, for Titus, who, it was feared, would be a second Nero, was known as the "love and delight of mankind." It is possible that his popularity was in some degree due to the fears which the depravity of his brother Domitian, who, it was known, was to succeed him, had begun to excite; but he had the tact to make himself liked by all. He seems to have been thoroughly kindly and good-natured; he delighted in giving splendid presents, and his memorable saying, "I have lost a day," is said to have been uttered one evening at the dinner table when he suddenly remembered that he had not bestowed a gift on any one that day.

Titus, like his father, spent money on great public works and in adding to the magnificence of Rome.

---

[1] Persons fond of watching the habits of birds may with little trouble provide a pleasing spectacle by adopting the plan, practiced by the late Mr. A. E. Knox, of hanging a lump of suet or tallow by a short string to the end of a flexible rod stuck aslant into the ground close to the window of a sitting-room. It is seldom long before a Titmouse of some kind finds the dainty, and once found visits are made to it until every morsel is picked off. The attitudes of the birds as they cling to the swinging lure are very diverting, and none but a Titmouse can succeed in keeping a foothold upon it.

[2] The common names given to this bird are so very inapplicable that it is a pity that "Silerella" (from *siler*, an osier) bestowed upon it by Sir T. Browne, its original discoverer, cannot be restored.

The Colosseum was completed and dedicated in his reign, with combats of gladiators, shows of wild beasts, and sham sea-fights and representations of some of the great Greek naval battles. He gave the city what we should now call "a people's palace" in his splendid baths, which surpassed those of Agrippa and of Nero, and supplied the mob with every luxurious appliance free of cost.

During his reign, in 79, occurred the memorable eruption of Vesuvius which destroyed Herculaneum and Pompeii. The emperor visited the scenes of desolation and contributed liberally to the relief of the distressed inhabitants. During his absence a fire raged for three days at Rome, in which the Capitol was burnt; then followed a pestilence, and again Titus not only helped freely with his purse, but took pains to acquaint himself with the sufferers and gave them his personal sympathy. Italy and the Roman world generally were quiet and peaceful during this brief reign. The only fighting was in Britain under Agricola, who in the year 80 carried the Roman arms into Scotland as far as the Tay. In the following September Titus died, being in his fortieth year, after a reign of two years and rather more than two months. On his deathbed he said, so the story went, that there was but one thing of which he repented: this was commonly supposed to point to his having spared to punish his brother Domitian, who had more than once plotted against his life, and whose succession to empire he must have felt would be a calamity for Rome. The verdict of history is on the whole favorable to Titus, and perhaps deservedly so; but the general feeling throughout the Roman world after his death was that he had been fortunate in the briefness of his reign.

An admirable account of this emperor will be found in Merivale's *History of the Romans under the Empire*, ch 60. (W. J. B.)

TITUS, one of the companions of St. Paul, was of Greek origin (Gal. ii. 3), and appears to have been among the apostle's earliest converts; he is first mentioned (Gal. ii. 1) as having accompanied Paul, then in the course of his second missionary journey, from Antioch to Jerusalem. Here the Judaizing brethren desired that he should be circumcised; but the liberty of the gospel was successfully maintained. He was afterwards sent by Paul from Ephesus to Corinth, with, it would seem, a letter, no longer extant, more than once referred to in 2 Corinthians (ii. 3, vii. 8; comp. vol. vi. p. 356). He rejoined the apostle with favorable reports from Corinth in Macedonia, and was again sent (from Philippi) with another epistle, probably what is now known as the second, to the Corinthians, and charged with the further duty of promoting the proposed collection for poor Christians in Judea. This is, practically all that is known of him from the undisputed Pauline epistles. He is nowhere mentioned in the Acts. In the pastoral epistle with which his name is associated he is represented (Tit. i. 5) as having been left by Paul in Crete to "set in order the things that are wanting, and ordain elders in every city." He is expected afterwards to join Paul at Nicopolis (iii. 12). In 2 Tim. iv. 10 he is spoken of as having gone to Dalmatia. Tradition, obviously resting on the Epistle to Titus, has it that he died in Crete as bishop at an advanced age.

TITUS, EPISTLE TO. See PASTORAL EPISTLES, vol. xviii. p. 353 *sq.*

TITUSVILLE, a city of the United States, in Crawford county, Pennsylvania, in 41° 38′ N. lat. and 79° 42′ W. long., stands upon Oil Creek, in the midst of the oil region of northwestern Pennsylvania. Its predominant industries have reference to the production, refining, and transportation of petroleum. It has two railroads—the Dunkirk, Allegheny, and Pittsburg, and the Buffalo, New York, and Philadelphia. The city had a population of 8639 in 1870 and of 9046 in 1880.

Titusville, originally a small lumbering town, began its career of prosperity in 1859, when oil was discovered in this region, and during the succeeding years it was the scene of very great activity. It was chartered in 1867, when at the zenith of its prosperity. Since that time it has settled down to a less feverish and more healthy growth.

TIUMEN. See TYUMEN.

TIVERTON, a borough of Devonshire, England, is finely situated in the midst of beautiful scenery at the confluence of the Lowman and the Exe, 14½ miles north of Exeter and 184 west-southwest of London. A branch line connects it with the Great Western, and the Exe Valley Railway with Exeter and Dulverton. The greater part of the town is on the left bank of the Exe; the four principal streets are wide and regular. Since 1262, when Amicia, countess of Devon, caused a stream of water to be directed from Norwood to Tiverton, a distance of 5 miles, every street has had a constantly flowing supply. At points now spanned by bridges there were formerly two fords, one over the Exe and the other over the Lowman; hence Twofordton and Twyfordton the former names of the town. There still remain the principal gateway and an octagonal turret of the ancient castle (now a private residence), built in 1106 by Richard de Riparus or Redvers, first earl of Devon, and the chief residence of the Redvers till the execution of Henry Courtenay, marquis of Exeter, in 1539. The most ancient part of the church of St. Peter is the Norman doorway; the embattled western tower is 120 feet in height. For Blundell's free grammar-school (1604) new buildings have recently been erected in the Tudor style. Among other educational establishments are the school of science and art, the blue coat charity school (1714; re-established as a middle boys' and middle girls' school in 1876), and the Chilcott free school (1611). The other principal public buildings are the market-house (1830–31), the infirmary (1852), the town-hall (1864), and several almshouses. Tiverton was formerly famed for its woollen manufacture, introduced in the 14th century; its annual returns in 1612 were estimated at £300,000, [$1,458,000], about 8000 persons being employed in the industry. It is now chiefly noted for its lace manufacture, established by John Heathcoat, the inventor of the bobbin net frame. The population of the municipal borough (area, 17,491 acres) in 1871 was 10,024, and in 1881 it was 10,462.

The town existed in Saxon times. In the reign of Edward the Confessor it was held by vassals or servants, and in Domesday it is entered as *terra regis*. In 1200 it had a market and three annual fairs. After the introduction of the woollen trade in 1353 it rapidly increased, and Camden states that the trade had brought it "much gain and glory." The town and castle were taken by Fairfax in 1645. Tiverton suffered from the plague in 1591 (when it had 5000 inhabitants), and from fire in 1598, 1612, and 1731. It was incorporated by James I. in 1615; but in 1732 its charter was forfeited, and a second was not bestowed till 1737. The borough was deprived of parliamentary representation in 1885.

See Harding's *History of Tiverton*, 2 vols., 1845.

TIVOLI (Lat. *Tibur*), a town of Italy, situated 17 miles east-northeast of Rome on one of the spurs of Monte Ripoli, 830 feet above the sea. Its position is very striking and beautiful; it stands partly at the edge of the lofty cliff over which the river Anio falls in a most imposing mass of water. The present aspect of the fall is very different from what it was in ancient times, as the water has undermined and carried away great masses of the rock. In 1881 the population of the town was 9730, and of the commune 10,297.

Ancient Tibur was founded, according to the legend adopted by the Roman poets, many centuries before Rome, by the Siculi.[1] They were expelled by a Greek named Tiburtus, the son of Catillus, who became the eponymous hero of

---

[1] Dion., i. 16, and Plin., *H. N.*, xvi. 87.

Tibur.[1] During the early historic period Tibur, which stood on the borders of the Sabine territory, was always a bitter enemy of Rome, and on many occasions allied itself to various peoples, even the Gauls, in their attacks on the city. With the rest of Latium, Tibur was finally conquered by Rome in 335 B.C., and on account of its constant enmity was treated with much severity, not being admitted to the Roman franchise till towards the close of the republican period. Almost no mention of Tibur occurs during the time of the empire; but the town is recorded to have suffered severely during the Gothic invasion in the 6th century.

Remains of its city wall still exist, built of squared blocks of tufa; but the whole circuit is not clearly determinable. Even the site of the large and wealthy temple of Hercules is doubtful, which stood in an extensive temenos, containing libraries and a porticus, where Augustus sometimes administered justice.[2] At the edge of the cliff still stands a small circular temple, of doubtful dedication, which once had eighteen columns, and closely resembled that in the Forum Boarium of Rome. Its cella walls are of concrete faced with opus reticulatum, and its columns of travertine; it dates from about the time of Christ. Its popular name is the "temple of the Sibyl."[3] Close by is another small prostyle-tetrastyle temple resembling that (so called) of Fortuna Virilis in Rome. Remains of the circuit wall of the forum also exist, with a large apsidal projection, as well as an extensive crypto-porticus, faced with blank arcading and divided internally by a row of twenty-eight columns. Tibur was a favorite summer residence of many wealthy Romans under the empire, and especially of Horace and Mæcenas.[4] One of the chief aqueducts of Rome, "Anio vetus," started from the Anio at Tibur. The ancient "lapis Tiburtinus" (modern travertine) was so called from its chief quarries at Tibur, where it has been during long ages deposited by the water of the river Anio.

Hadrian's villa, which stands at the foot of the Tibur spur of hill about 2 miles distant, is one of the most important Roman remains in the world. Between 1870 and 1882 the greater part of its immense area was excavated; the whole circuit was once no less than 8 miles. The scheme of this wonderful group of buildings was the fancy of the rich and highly educated emperor Hadrian, who desired to reproduce, within a short distance of Rome, a number of the chief Greek sites and buildings which he had visited in different parts of the world. Besides his own palace he built a large stoa pœcile, copied from that at Athens, an odeum, a lyceum, an academy (with its gardens, halls, and porticus), libraries, Latin and Greek theatres, a stadium, palæstra, hippodrome, baths, and many temples. Large gardens, divided into an artificial "Vale of Tempe," "Elysian Fields," and "Tartarus," were watered by a winding stream named the "Euripus." In another place stood a "serapeum," copied from that at Alexandria, and filled with pseudo-Egyptian statues and reliefs, many of which have been recently unearthed. Barracks for the prætorian guard and rows of dwellings for slaves completed this magnificent group of buildings. In many parts the existing remains are well preserved and in some cases the uses of the different buildings can be determined.[5] The main walls are of concrete faced with mixed brick and opus reticulatum, once wholly covered with magnificent Oriental marbles and crowded with fine Greek and Græco-Roman sculpture; mosaic of marble and glass was lavishly used for floors, walls, and vaults, together with the most elaborate painted decorations. A large number of fine works of art have been discovered here, such as the mosaic of "Pliny's doves" and the Faun in rosso antico now in the Capitol. It is probable that the Venus de' Medici came from this villa, together with many other statues found in the 16th century whose *provenance* is now forgotten.

TLAXCALA (*Tlascala, i.e.*, "House of Bread"), an historical city of Mexico, capital of the state of Tlaxcala, which nearly coincides with the old native republic of Tlaxcala, occupying the easternmost of the four sections into which the Anahuac plateau is here divided by ranges of hills, between 19° and 20° N. lat. The modern town, standing on the site of the old Indian capital, lies (in 19° 19′ N. lat., 98° 6′ W. long.) on the little river Papagallo (Atoyac, formerly Zahuatl), which flows between two hills at an altitude of considerably over 7000 feet, some 30 miles north of La Puebla and 170 by rail from Vera Cruz. Tlaxcala was founded probably about the close of the 13th century, when the Tlaxcaltecs, a branch of the Nahuatl race closely akin to the Aztecs, withdrew from the western side of the central lacustrine district and established a powerful democratic state in a somewhat secluded, hill-encircled, but highly productive tract, 90 miles in length by 70 in breadth, with a total area of over 1550 square miles. The Tlaxcaltecs, hereditary foes of the Aztecs, became, after a short resistance (September, 1519), the firm allies of the Spaniards, their co-operation contributing largely, if not mainly, to the overthrow of the Mexican empire. But the result was the enslavement of Tlaxcala itself, the general decay of the country, and the dispersion of most of the inhabitants by Cortes. Although now reduced to a population of a little over 5000, or, including the commune, to 36,000, and with no monuments beyond a fine church, an old episcopal palace, and a town-hall, the city at the time of the conquest was a very large place, containing nearly as many inhabitants as the whole of the modern state (130,000). When occupied by the Spaniards, its size and splendor excited the admiration of Cortes, who describes it in somewhat exaggerated language as "much larger and much stronger than Granada, with as fine buildings and much more people than Granada had at the time it was captured, also much better supplied with the things of the earth" (*Cartas*, 67). It was disposed in four distinct quarters separated by high stone walls, each with a palace for the ruling chief, besides temples, and stone buildings for the nobles. But most of the other houses were low mud or adobe structures. In the daily market, which was said to be frequented by 30,000 people, were exposed for sale the products of the surrounding country,—maize, maguey (extracted from the aloe), and chilli pepper; to these are now added wheat, barley, pease, lentils, and a great variety of fruits.

A prominent feature of the landscape is the Sierra de Malintzi, or Malinche, that is, "Lord of Marina," a name given to Cortes after his alliance with the "heroine of the conquest." The Sierra (originally Matlacuezatl), which rises grandly (more than 16,000 feet) above the plateau, takes a prominent place in Tlaxcaltecan mythology, owing to the peculiar shape of its summit, representing in rough outline the body of a native woman lying at full length in its grave and partly wrapped in its cerements. There are some woollen manufactures, centred chiefly in the capital, and also a few silver, copper, lead, and coal mines in the San Ambrosio and San Mateo ranges; but the state is essentially agricultural, yielding large annual crops of maize and wheat, the total produce being valued at over £1,000,000 [$4,860,000].

TLEMCEN, or **TILIMSÁN**, a town of Algeria, chef-lieu of an arrondissement in the department of Oran, lies 86 miles S.W. of Oran, 2625 feet above the sea, on a terrace on the northern slope of a range of rocky hills (3430 feet). Its white minarets, towers, and battlements rise picturesquely above the surrounding verdure, which is nourished by numerous springs, and even in ancient days gave rise to the Roman name *Pomaria*. The various quarters are grouped around the principal mosque,—the Jewish to the southwest, the Moorish to the southeast, that of the merchants to the northeast, while the new town with the civic buildings lies to the northwest. Of the sixty-four mosques which existed at the period of the French conquest, several have disappeared. The great mosque has a minaret adorned with marble columns, and cased with mosaic of the most varied designs; a fountain of alabaster stands in the alabaster-paved inner court; and seventy-two columns support the pointed arches of the interior. The mosque of Abul Hasan, now used as a French and Arab school, has two series of arches, which rest on alabaster pillars, and the courts are ornamented by sculptures of great beauty and richness; the delicately carved cedar ceiling bears traces of polychromatic painting. The mosque of El-Halawi is specially interesting for the sculptured capitals of its magnificent alabaster columns. Tlemcen, besides numerous other mosques, possesses a fine modern Roman Catholic church in the Byzantine style and five synagogues. The military authorities occupy the Mehuar or citadel, built in 1145, which separates the Jewish and Moorish quarters, and was formerly the palace of the rulers of Tlemcen. Only the mosque and the battlemented wall, flanked by two towers, remain of its former magnificence. Among the antiquities preserved in the museum is the epitaph of Boabdil, the last king of Granada, who died at Tlemcen in 1494. The vast basin under the old walls, now used as a reservoir (720 feet in length, 490 in width, and 10 in depth), was apparently made for naval exhibitions by the sovereigns of Tlemcen. The barracks of the Spahis occupy all that remains of Kissaria, a settlement of European merchants from Pisa, Genoa, Catalonia, and Provence. Leather, saddles, Turkish slippers, arms, and woollen goods are manufactured in Tlemcen; the production of oil and flour and market-gardening occupy Europeans and natives; good tobacco is also grown. There is an active trade in cattle, wool, grain, and fruit. A railway (37 miles) is being built (1887) to connect Tlemcen with Rahgun, its port. In 1886 the population (natives, Europeans, and Jews) was 19,745 (26,395 in the commune).

[2] See App., *Bell. Civ.*, v. 24; and Suet., *Aug.*, 72.

[3] It has also been called the temple of Vesta, but the real site of this last was on the other side of the river.

[4] Hor., *Od.*, i. 7, 10, and ii. 6, 5.

[5] Many of the names given to different parts by the Roman antiquaries are based on mere conjecture.

The town was originally at Agadír (*Pomaria*), to the east of the present site, where Roman inscriptions have been found. At the time of the Arab invasion the district was held by the Bení Ifren tribe of Zenáta Berbers, who ultimately founded here the sovereignty of the Bení Ya'lá (1002–1080). In 1080 the Almoravid king, after besieging and sacking the place, built a new town on the site of his camp. His successors reigned sixty-five years, when after holding Agadír four years against the enemy, they were overcome by the Almohades, who massacred the inhabitants, rebuilt, enlarged, and repeopled the ruined town, and surrounded Tlemcen and Agadír with a common wall. Tlemcen now flourished greatly under the 'Abd al-Wād, also a Zenáta dynasty, who ruled first for the Almohades and after 1242 as nominal vassals of the Hafsites of Tunis. In 1337 their power was temporarily extinguished by the Merinids, who built the town of Mansura, west of Tlemcen. They left some fine monuments of the period of their ascendency, which lasted twenty-two years. Once more, under the 'Abd al-Wād, from 1359 to 1553, Tlemcen enjoyed prosperity, when it had a population of 125,000, an extensive trade, a brilliant court, a powerful army, and its finest buildings were reared. The Spanish occupation of Oran struck a fatal blow at the European commerce of the town, which gradually lost all its territory to the Turks after they had seized Algiers. When the French entered Algeria the sultans of Morocco were worsted by the Kuluglis in their attempt to hold the town. In 1834, and again in 1837, Abd el-Kader sought to re-establish the ancient empire of Tlemcen, but the French definitely took possession in January, 1842.

TOAD. This animal belongs to the Anurous division of the *Amphibia*, and toads and frogs are the only representatives of the *Anura* or *Batrachia* indigenous to Britain. To an ordinary observer the toad is proved to be an amphibian by its moist soft skin, an anuran or tailless amphibian by the want of a separate tail. The toad differs from the frog in the following points: It has no teeth on either of its jaws or on the roof of its mouth, while the frog has a series of fine teeth on the upper jaw and also teeth on the palate; the tongue in both animals is attached in front and free behind,[1] but that of the frog is forked at its free extremity, that of the toad is not; the skin of the toad is rough with large protuberant warts, while that of the frog is smooth; the body of the toad is more globular and puffy than that of the frog; the hind legs in the toad are shorter, and the posterior digits not so completely webbed, the animal being more terrestrial in its habits than the frog. In the toad, as in the frog, there are four digits anteriorly, five posteriorly. The warts of the toad's skin contain large cutaneous glands, which secrete a thick yellowish fluid with acrid properties, capable of irritating and producing slight inflammation on the human skin. The use of this secretion is probably to protect the toad from being devoured by carnivorous animals. Like other *Amphibia*, it has a large membranous bladder communicating with the terminal part of the intestine—the allantoic bladder.—in which fluid accumulates, probably from the kidneys, though the ureters do not open directly into the bladder. The toad, when handled or alarmed in any way, ejects the contents of its bladder. Owing to these peculiarities and its appearance, the animal is commonly regarded with loathing, and credited with far more poisonous properties than it possesses. In its breeding habits the toad resembles the frog: its eggs are fertilized externally at the moment of extrusion, as in the frog, the parents resorting to the water for the purpose of reproduction. The ova are laid in spring, and are arranged, not in shapeless masses, but in a string containing a double series of eggs adhering by their gelatinous envelopes; the string extends to a length of three or four feet. The tadpoles are similar to those of the frog, but blacker; their metamorphosis takes place in the same manner, the three pairs of external gills being first absorbed and replaced for a time by internal gills, which are in their turn lost, the branchial slits being closed by the coalescence of the opercular membrane with the skin. The metamorphosis is complete in autumn. The toad is carnivorous, feeding on flies and other insects and worms. It hibernates in winter, passing its period of torpidity in holes or burrows in the earth. The finding of toads in a state of hibernation has given rise to stories of their being found in the centre of trunks of trees or imbedded in solid rock. The myth of the jewel in the head (Shakespeare) is probably founded on the brightness of the eyes, in which the iris is flame-colored.

There are two kinds of toad in Britain,—the Common Toad, which is almost black in color, and the Natter-jack Toad, which is lighter, smaller, and has a bright yellow line along the middle of the back. The length of the common toad is 3½ inches, of the natter-jack 2¾ inches. The male natter-jack possesses a bladder or vocal sack beneath the throat communicating with the mouth, which acts as a resonator to its voice; its cry is "gluck-gluck." The vocal sack is absent in the common toad, and only incompletely developed in the Green Toad of the Continent.

In zoological classification the toad belongs to the genus *Bufo*, first constituted by Laurenti in the *Synopsis Reptilium*, of which the following diagnosis is given in the *Brit. Mus. Cat. Batr. Sal.*, 1882:

Pupil horizontal. Tongue elliptical or pyriform, entire and free behind. Vomerine and maxillary teeth none. Tympanum distinct or hidden, seldom absent. Fingers free; toes more or less webbed; the tips simple or dilated into small disks. Outer metatarsals united. Omosternum generally missing; if present cartilaginous; sternum a cartilaginous plate, sometimes more or less ossified along the median line. Diapophyses of sacral vertebræ more or less dilated. Terminal phalanges obtuse or triangular. Distribution cosmopolitan, except Australia.

Bufo vulgaris, Laurenti, the Common Toad, is thus distinguished. Crown without bony ridges. First finger as long as or longer than the second. Parotids distinct. Tympanum smaller than the eye. Toes half webbed; no tarsal fold; subarticular tubercles of toes double. The species is widely distributed, occurring throughout Europe, Asia, and northwest Africa.

Bufo calamita, Laurenti, the Natter-jack Toad, shows the following differences from *B. vulgaris*: toes not half webbed; tympanum rather indistinct; a tarsal fold. It is distributed throughout Europe.

According to Boulenger there are 77 species of *Bufo* known, of which 35 are confined to the Old World, the rest to the American continent. No species is common to the two great continents. The only other species occurring in Europe besides the two which are found in Britain is *Bufo*

---

[1] [The *Rhinophrynidæ*, comprising a single genus of tropical America, has the tongue free in front, according to T. Gill.—Am. Ed.]

viridis, Laurenti, which ranges throughout Europe, Asia, and North Africa.[1]

TOBACCO consists of the leaves of several species of *Nicotiana* (nat. ord. *Solanaceæ*), variously prepared for use as a narcotic. While it is principally manufactured for smoking, a large amount is also prepared for chewing, and to a more limited extent it is taken in the form of snuff. Under one or other of these forms the use of tobacco is more widely spread than is that of any other narcotic or stimulant.

History.

Although the fact has been controverted, there cannot be a doubt that the knowledge of tobacco and its uses came to the rest of the world from America. In November, 1492, a party sent out by Columbus from the vessels of his first expedition to explore the island of Cuba brought back information that they had seen people who carried a lighted firebrand to kindle fire, and perfumed themselves with certain herbs which they carried along with them. The habit of snuff-taking was observed and described by Ramon Pane, a Franciscan, who accompanied Columbus on his second voyage (1494–96), and the practice of tobacco-chewing was first seen by the Spaniards on the coast of South America in 1502. As the continent of America was opened up and explored, it became evident that the consumption of tobacco, especially by smoking, was a universal and immemorial usage, in many cases bound up with the most significant and solemn tribal ceremonies.

The term tobacco appears not to have been a commonly used original name for the plant, and it has come to us from a peculiar instrument used for inhaling its smoke by the inhabitants of Hispaniola (San Domingo). The instrument, described by Oviedo (*Historia de las Indias Occidentales*, Salamanca, 1535), consists of a small hollow wooden tube shaped like a **Y**, the two points of which being inserted in the nose of the smoker, the other end was held into the smoke of burning tobacco, and thus the fumes were inhaled. This apparatus the natives called "tabaco"; but it must be said that the smoking pipe of the continental tribes was entirely different from the imperfect tabaco of the Caribees. Benzoni, on the other hand, whose *Travels in America* (1542–56) were published in 1565, says that the Mexican name of the herb was "tabacco."

The tobacco plant itself was first brought to Europe in 1558 by Francisco Fernandes, a physician who had been sent by Philip II. of Spain to investigate the products of Mexico. By the French ambassador to Portugal, Jean Nicot, seeds were sent from the Peninsula to the queen, Catherine de' Medici. The services rendered by Nicot in spreading a knowledge of the plant have been commemorated in the scientific name of the genus *Nicotiana*. At first the plant was supposed to possess almost miraculous healing powers, and was designated "herba panacea," "herba santa," "sana sancta Indorum"; "divine tobacco" it is called by Spenser, and "our holy herb nicotian" by William Lilly. While the plant came to Europe through Spain, the habit of smoking it was initiated and spread through English example. Ralph Lane, the first governor of Virginia, and Sir Francis Drake brought with them in 1586, from that first American possession of the English crown, the implements and materials of tobacco smoking, which they handed over to Sir Walter Raleigh. Lane is credited with having been the first English smoker, and through the influence and example of the illustrious Raleigh, who "tooke a pipe of tobacco a little before he went to the scaffolde," the habit became rooted among Elizabethan courtiers. During the 17th century the indulgence in tobacco spread with marvellous rapidity throughout all nations, and that in the face of the most resolute opposition of statesmen and priests, the "counterblaste" of a great monarch, penal enactments of the most severe description, the knout, excommunication, and capital punishment.

Botany.

The species of *Nicotiana* number about fifty, but those of which the leaves are used as sources of tobacco are few. With the exception of two species, one native of New Caledonia, the other proper to Australia, they are all of American origin. They form two well-defined groups, the first of which is characterized by the possession of an elongated corolla tube, red in color, the plants having a single unbranched stalk which attains a height of from 5 to 7 feet; while to the second group belong such as have a swollen corolla tube of a greenish-yellow color, and a much-branched stem reaching a height of only from 2 to 5 feet. The type of the first group is the Virginian Tobacco, *N. Tabacum*, while the best known representative of the second is the Green Tobacco, *N. rustica*. These two species, together with their numerous varieties, and with the Persian Tobacco, *N. persica*,—the source of the famous Tumbeki or Shiraz tobacco,—are the sole sources of commercial tobacco. *N. Tabacum* is the species from which the tobaccos of Cuba, the United States, and the Philippine Islands, and the Latakia of Turkey, are derived, and it is thus the source of not only the greater proportion of the tobacco of commerce but also the most highly prized and valuable of its varieties. *N. rustica*, originally a native of Brazil, is cultivated to a considerable extent in South Germany, Hungary, and the East Indies.

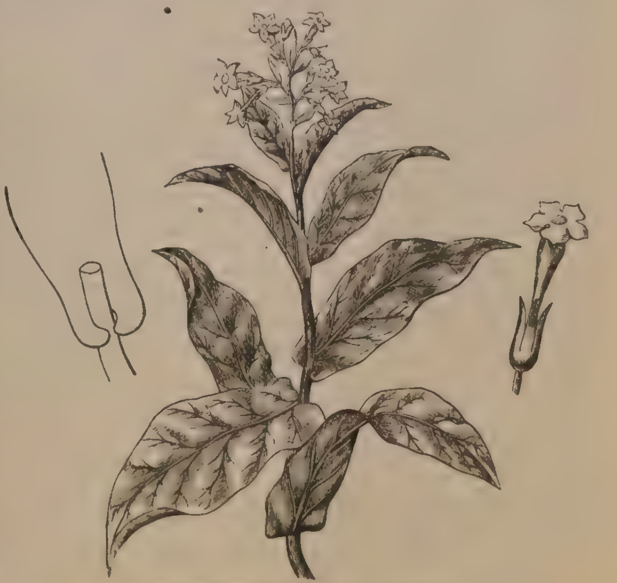

FIG. 1.—Flowering Top of *N. Tabacum*.

The Virginian tobacco-plant, *N. Tabacum*, is a coarse rank-growing annual, with a simple unbranched cylindrical stem which attains a height of 6 feet and upwards, terminating in a panicle of pink flowers. It has alternate simple oblong lanceolate leaves, those at the lower part of the stem being slightly stalked, and of large size, reaching to two feet in length, while the upper are semi-amplexicaul and of variable outline. The seeds are brown in color, with a rough surface, of minute size, and exceedingly numerous, as many as 40,000 having been counted on a single plant. The whole of the green parts of the plant are covered with long soft hairs which exude a viscid juice, giving the surface a moist glutinous feeling. The hairs are multicellular, and of two kinds, one branching and ending in a fine point, while the other, unbranched, terminates in a clump of small cells. Stomata occur on both surfaces of the leaves, and, with the peculiar hair structure, render the microscopic appearance of the plant highly characteristic.

Cultivation.

Tobacco will flourish over wide areas and in very dissimilar climates, but it is best suited for regions having a mean temperature of not less than 40° F. and where early autumn frosts do not occur. It develops the most highly appreciated qualities in tropical lands possessed of a comparatively dry climate.

---

[1] [The common toad of the United States is the *Bufo lentiginosus*, found from the Atlantic coast to Texas.—AM. ED.]

Tobacco is a most exhausting crop, and requires rich and abundant manuring, the character of which exercises a distinct influence on the quality of the product. A crop grown under such widely different conditions of climate and agriculture as is the case with tobacco must of necessity be subject to varied treatment both in cultivation and in curing, and here we can refer only to the general features of the growing and securing of the crop.

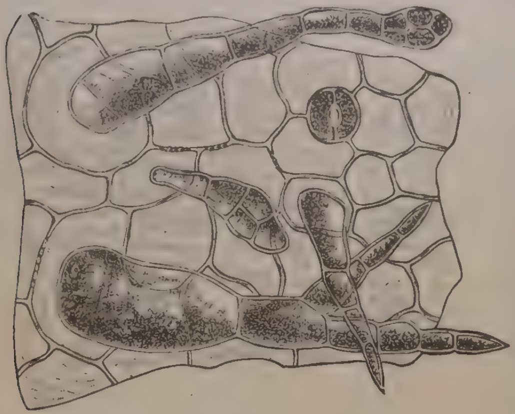

Fig. 2.—Microscopic Structure of Tobacco Leaf.

In European cultivation, the tobacco-seed is sown in a hotbed about the end of March. The seed-beds are kept covered with damp straw or withered leaves till the seedlings appear above the ground, after which the covering is removed, and to protect the young plants from frost, to which they are extremely sensitive, the beds are covered at night with mats. So soon as the plants can be handled, they are picked out in rows in a garden bed, where they remain protected from night frost till they have developed five or six leaves and have a height of 3 to 4 inches. They are then ready for transplanting, by preference in moist weather, into prepared drills 20 to 25 inches apart in the field. The transplanting is done about the end of May, or earlier in localities free from night frosts, and in dry weather the field is plentifully soused with liquid manure. The plants are carefully weeded and attended to, and the soil is frequently stirred with narrow hoes until the period when they show symptoms of flowering. This may be when they are only 3 feet high, or not until they have reached their proper height of 6 or 8 feet; but the flowers must not be allowed to form, except in the case of a few plants left purposely for seed. To obtain fine and strong leaves on the plant is the great object of the cultivator, and a fine tobacco plant ought to have from eight to twelve large succulent leaves. Cultivators commonly diminish the number of leaves by "topping" or breaking off the top, under the idea that the remaining ones will afford the strongest tobacco. Suckers or shoots near the root are carefully removed, and everything is done to concentrate the strength of the plant in the leaves. Every leaf injured by insects is removed, and the crop is watched until the leaves have a yellowish tint and begin to droop, when they are fit to be gathered. This is usually in September, so that the plants from the time of their insertion on the mounds, have occupied the ground four months, during which time they have been subject to many vicissitudes,—from the attacks of insects, from a disease called "firing," caused by the long continuance of very wet or very dry weather, and from the occurrence of autumn frosts while the crop is yet in the field.

In the harvesting of the tobacco crop several distinct methods are followed. In ordinary European cultivation the ripe leaves are separated from the standing stalks in the field. The three lower root-leaves are first stripped off and laid, face downward, around the root to wilt, after which they are bundled and carried to the barn. Afterwards the remainder of the leaves are separated, working from the top downwards, and, similarly, they are spread on the ground till by wilting they lose their brittleness. They are then bundled and packed, tops upward, closely on the floor of the barn for some time to sweat, by which the uniform ripening and subsequent favorable drying are promoted. The bundles are carefully watched to prevent overheating, which would blacken and injure the leaves. In the tobacco-growing districts of the United States the entire plant is cut down in the field close to the ground, then the stalks are spitted on long rods or laths, care being taken to keep the leaves from touching each other, and on these rods they are carried and hung in the barn or curing-house for drying.

Curing.

The curing of the leaves which follows has for its objects the drying and preservation of the tobacco, and by a process of slow fermentation, the modification of certain of the leaf constituents, and the development of the characteristic aroma of the substance. Subject to various minor modifications, the process of curing is carried out either slowly by the air-cure process or rapidly by fire-curing. The European cultivators, who generally cure by the slow process, either spit the leaves through the middle on a long rod or string them on a cord, taking care to keep each leaf from touching its neighbor. These rods or cords of leaves are suspended in a barn or curing-shed in a way which allows the free circulation of the air, and at the same time brings the whole contents of the shed equally under the drying influence of the air currents. When the weather is clear and dry, free circulation of the air is in every way promoted, but on humid days the moist air is excluded and sometimes artificial heat is required to prevent mildew and rotting of the leaves. Under favorable circumstances the tobacco will be dry and ready for further treatment in from six to eight weeks, and the leaves should then have a fine bright warm brown color.

In the United States the quick-drying process by artificial heat is employed principally for the preparation of export tobacco. Formerly the heat was obtained by means of an open charcoal fire within the curing-barn, but now the structure is heated by a system of flues which permits of the burning of any kind of fuel. For dark shipping tobacco, the entire plants, cut down close to the ground, are immediately housed, and at once dried off. Red shipping qualities are prepared by leaving the cut stems either in the field or hung on scaffolds in the barns for a few days to wilt and wither in the air, after which they are dried by artificial heat. In the treatment of both dark and red kinds the temperature within the barn is gradually raised till it reaches 170° F., and the drying is complete in from four to five days.

By whichever way treated, the tobacco-leaf at this stage is brittle, and cannot be handled without crumbling to powder. The contents of the barn are therefore left till moist weather occurs, and then by the admission of atmospheric air the leaf blades absorb moisture and become soft and pliant. In this condition the leaves are stripped from the stems, sorted into qualities, such as "lugs," or lower leaves, "firsts," and "seconds." These are made up into "hands," or small bundles of from six to twelve leaves. Each bundle is tied round with a separate leaf, and in this condition the tobacco is ready for bulking for fermentation.

For fermentation the tobacco, whether in bundles, hands, or separate leaves, is piled up or bulked on the floor in a barn into a solid stack to the height of 5 or 6 feet. Within this stack a process of fermentation is quickly set up, and the temperature of the mass rises steadily till it reaches about 130° F. Great care is now taken to prevent overheating, and to secure the uniform fermentation of all the tobacco. The pile is from time to time taken down and rebuilt, the tobacco from the top going to the bottom, and that exposed at the edges being turned in to the centre. In from three to five weeks the fermentation should be sufficiently carried out, and the leaves then have a nice uniform brown color. The cured stack may in this condition be piled up in store without fear of further fermentative activity, till, with increasing summer heat, it is subject to the May sweat, which renders further watchfulness necessary.

Chemistry.

The components of tobacco, like those of all vegetable matters, arrange themselves under the three heads of water, mineral acids and bases (which pass into the ash on combustion), and organic substances. According to an investigation carried out by Beauchef in Gay-Lussac's laboratory, the amount of ash from 100 parts of matter dried at 100° C. [212° F.] is in the roots 6 to 8, in the stems 10 to 13, and in the ribs and leaves 18 to 22 per cent. The greater part of the ash consists of insoluble salts, principally carbonate of lime. The soluble part consists largely of potash salts (KCl, K_2CO_3, K_2SO_4), which may amount to from 5 to 35 per cent., and it is remarkable that tobacco contains no soda. In addition to the mineral salts proper, tobacco contains salts of ammonia and nitrates. In the leaf the proportion of nitrates is greater in the rib than in the laminæ. In the former it may amount to as much as 10 per cent. (calculating the nitric acid as KNO_3). According to Schloesing (*Ann. Chim. Phys.*, [3], xl. 479), the proportion of (combined) nitric acid in tobacco has nothing to do with its combustibility, that is, the length of time a lighted cigar will glow spontaneously. This quality is a function chiefly of the potash present in combination with organic acids. An incombustible tobacco, *i.e.*, a tobacco which does not keep a glowing ash, contains its organic acids in the form of lime and magnesia salts. The explanation is that, while organic potash salts, being fusible, yield when heated a porous charcoal which glows readily, the corresponding infusible lime salts yield a compact charcoal which is far less combustible. A combustible tobacco can be rendered incombustible by the incorporation of sulphate or chloride of calcium or magnesium. By cultivation experiments in a potash-free soil, it has been ascertained that chloride of potassium used as a manure does not add to the organic potash salts in the leaves, but the sulphate, carbonate, and nitrate do give up their potash for the formation of organic salts.

Subjoined is an enumeration of the proximate organic components of tobacco leaves, and their relative proportions in 100 parts, according to the numerous analyses made in the laboratories of the French state tobacco factories:

Nicotine, $C_{10}H_{14}N_2$, a liquid volatile alkaloid, from 1.5 to 9 per cent.

Essential oil,—according to Schloesing, an important element in the flavor of tobacco, although its proportion is exceedingly small.

Nicotianine, a solid camphor-like body to which, according to other authorities, the odor of tobacco is principally due.

Malic and citric acids, together 10–14 per cent., calculated as anhydrides.

Acetic acid, very little in fresh leaves, but increasing in their fermentation. In snuff it may rise to 3 per cent.

Oxalic acid, 1 to 2 per cent.

Pectic acid, about 5 per cent.

Resins, fats, and other bodies extractable by ether, 4 to 6 per cent.

Sugar, little in the leaves, more in the stems; in the fermentation it disappears.

Cellulose, 7 to 8 per cent.

Albuminoids, calculated from the nitrogen not present as nicotine, nitrates, or ammonia, about 25 per cent.

Excepting the nicotine, the several organic components of the leaves develop, roughly speaking, *pari passu* until fructification, when certain components are attracted to the fruit, suffering chemical changes while so moving. The nicotine determines the strength of a tobacco, but not its flavor or aroma. The manure supplied to a tobacco field does not increase the proportion of nicotine, but affects only the weight of the crop. The percentage of nicotine in the leaves may to some extent be modified in cultivation,—plants wide apart developing few leaves, but these thick, fleshy, and rich in nicotine, while closely packed plants throw out numerous but thin and membranous leaves having little nicotine. The proportion of nicotine present increases with the age of the plant. Schloesing found in leaves at various stages of growth the following percentage of nicotine: May 25 (very young leaves), 0.79; July 18, 1.21; Aug. 6, 1.93; Aug. 27, 2.27; Sept. 8, 3.36; Sept. 25, 4.32.

Regarding the changes which take place in the manufactured leaf, we take the case of snuff, because with it the chemical changes are carried farthest, and yet, qualitatively speaking, they are of the same nature as those which smoking tobacco undergoes. In the fermentation begun in curing and continued in the sauced leaf, the malic and citric acids and the nicotine undergo partial oxidation. The oxalate of lime and the pectates remain almost unchanged, and there are formed, of intermediate (not fully oxidized) bodies, ammonia, acetic acid, and black humic acid, the last giving to snuff its dark color. A little methyl-alcohol is also at the same time formed. At this stage the tobacco-leaf is acid in reaction; but after it is powdered, and again submitted for a prolonged period to a slow fermentation in air-tight boxes, it becomes decidedly alkaline by the ammonia, because, while acetic acid continues to be formed and the ammonia and nicotine remain what they are, the malic and citric acids are progressively destroyed. Unless snuff contains free ammonia it is "flat," and destitute of pungency.

As to the composition of tobacco smoke, numerous investigations have been made. Kissling (*Ding. Polyt. Jour.*, ccliv. 234-246), experimenting on cigars, found that a large proportion of the nicotine passes unaltered into the smoke. Dealing with a tobacco containing 3.75 per cent. of nicotine, he recovered from the smoke 52.02 per cent. of the total nicotine consumed, while in the unconsumed remains of the tobacco the proportion of nicotine was increased to 5.03 per cent. With a second sample of tobacco, having likewise 3.75 per cent. of nicotine, the smoke yielded only 27.83 per cent. of the total nicotine consumed, and the percentage in the unconsumed remains was raised to 4.51. From a tobacco containing only 0.30 of nicotine he recovered 84.23 of nicotine in the smoke. The composition of tobacco smoke is highly complex, but beyond nicotine the only substances found in appreciable quantities are the lower members of the picoline series.

Commercial varieties.

The commercial varieties and the sources of supply of leaf-tobacco are exceedingly numerous. Special qualities of tobacco, as of wines, etc., belong to particular localities, outside of which they cannot be cultivated. These tobaccos are therefore natural monopolies. Moreover, as is also the case with wines, the crops vary in richness and delicacy of flavor with the seasons of their growth, so that in certain years the produce is of much greater value than in others. Further, the properties of certain classes of tobacco render them specially suitable for cigar-making. Others are best fitted for smoking in pipes; and there are numerous qualities which are valuable for snuff-making. National tastes and habits again frequently determine the destination of tobacco. Thus heavy, strong, and full-flavored cigars and tobaccos are in favor in the United Kingdom, while on the Continent lighter and more brisk-burning qualities are sought after, and the materials consumed in the kalians of Persia and the East are not suitable for use in the short pipes of the Western nations.

Of cigar tobaccos the most valuable qualities in the world are cultivated in the northwest portions of the island of Cuba. The district of Vuelta Abajo is the source of the highest quality, after which comes the produce of Partidas and Vuelta Arriba. A large portion of the tobacco is made into cigars in the island, but considerable quantities are also exported to Europe and the United States for mixing with commoner qualities to give Havana character to the home-made cigars. In recent years a large export of tobacco from Brazil, especially from the province of Bahia, has sprung up, most of which goes to Germany and Austria for cigar-making. The "seed-leaf" tobacco of Pennsylvania, Connecticut, and Ohio, grown from Havana seed, is devoted to cigar-making in the United States. In the East the most important cigar-tobacco region is the Philippine Islands, from which come the well-known Manila cheroots and cigars and a large quantity of leaf-tobacco of distinctive aroma. Immense quantities of cigar tobacco are also exported from Java and Sumatra, most of which passes through the markets of Amsterdam and Rotterdam. In the Madras presidency and in Burmah cigar tobacco is largely cultivated, the strong heavy qualities of which are well known to the British public in the Burmese, Lunka, and Dindigul cheroots.

Of ordinary smoking tobacco, among the most esteemed qualities are Varinas or kanaster, grown in the districts of Varinas, Merida, Margarita, etc., in Venezuela. The name kanaster, which covers several varieties of tobacco from South America, is given on account of the wicker baskets (Span. *canasta*) in which the material is packed for export. The tobacco regions of the United States—Kentucky, Maryland, Virginia, and Ohio—send great supplies of smoking leaf of various qualities into the European market, especially into the United Kingdom, which is almost exclusively supplied from these sources. Smoking tobaccos of the highest quality, rivalling indeed the cigar tobacco of Cuba in flavor and value, are grown in Turkey, and specially in the province of Salonica. The famous Latakia of the English smokers is produced in the province of Saida, in the northern part of Syria (see LATAKIA), and throughout Asiatic Turkey there is an extensive cultivation and export of smoking tobacco.

Manufacture.

In the manufacture of tobacco for smoking, we have to do with the numerous forms of tobacco used for smoking in pipes, embracing cut smoking mixtures, cake or plug, and roll or spun tobacco. Under this heading come also the cigar and cigarette manufacture.

The raw material in the warehouses is of various qualities: some is strong, rough, and harsh, and so is unfit for ordinary smoking; other samples are mild and fine, with aromatic and pleasant flavor, but devoid of strength. By a proper mixing and blending, the manufacturer is enabled to prepare the smoking mixture which is desirable for his purpose; but certain of the rough, bitter qualities cannot be manufactured without a preliminary treatment by which their intense disagreeable taste is modified. The storing of such tobacco for a lengthened period matures and deprives it of harshness, and the same result may be artificially hastened by macerating the leaves in water acidulated with hydrochloric acid, and washing them out with pure water. The most efficient means, however, of improving strong, ill-tasting tobacco is by renewed fermentation artificially induced by moisture and heat.

Smoking mixtures.

The manufacturer, having prepared his mixture of leaves, proceeds to damp them, pure water alone being used in the United Kingdom, whereas on the Continent and in America certain "sauces" are employed, which consist of mixtures of aromatic substances, sugar, liquorice, common salt, and saltpetre, etc., dissolved in water. The primary object is to render the leaves soft and pliant; the use of the sauces is to improve the flavor and burning qualities of the leaves used. When uniformly damped, the leaves are separately opened out and smoothed, the midrib, if not already removed, is torn out, except when "bird's eye" cut is to be made, in which mixture the midrib gives the peculiar "bird's eye" appearance. The prepared tobacco, while still moist and pliant, is pressed between cylinders into a light cake, and cut into fine uniform shreds by a machine analogous to the chaff-cutter. The cut tobacco is now roasted, partly with the view of driving off moisture and bringing the material into a condition for keeping, but also partly to improve its smoking quality. The roasting is most simply effected by spreading it on heated slabs, on which it is constantly turned; but such a method does not yield uniform results, and it exposes the workers to a most deleterious atmosphere and noxious fumes. A roasting machine is in use, which consists of a revolving drum in which the tobacco is rotated, gradually passing from one end to the other, and all the time under the influence of a current of heated air passing through it.

Roll tobacco.

For roll, twist, or pigtail tobacco the raw material is damped or sauced as in the case of cut tobacco. The interior of the roll consists of small and broken leaf of various kinds, called "fillers;" and this is enclosed within an external covering of large whole leaf of bright quality, such leaves being called "covers." The material is supplied to the twisting machinery by an attendant, and formed into a cord of uniform thickness, twisted and wound on a drum by mechanism analogous to that used in rope-spinning. From the drum of the twisting machine the spun tobacco is rolled into cylinders of various sizes. These are enclosed in canvas, and around the surface of each stout hempen cord is tightly and closely coiled. In this form a large number, after being cooked or stoved in moist heat for about twenty-four hours, are piled between plates in an hydraulic press, and subjected to great pressure for a month or six weeks, during which time a slow fermentation takes place, and a considerable exudation of juice results from the severe pressure. The juice is collected for use as a sheep-dip.

Cake tobacco.

Cake or plug tobacco is made by enveloping the desired amount of fillers within covering leaves of a fine bright color. A large number of such packages are placed in moulds, and submitted to powerful pressure in an hydraulic press, by which they are moulded into solid cakes. Both cake and roll tobacco are equally used for smoking and chewing; for the latter purpose the cake is frequently sweetened with liquorice, and sold as honey-dew or sweet cavendish.

Cigars.

For cigar-making the finest and most delicately flavored qualities of tobacco are generally selected. A cigar consists of a core or central mass of fillers enveloped in an inner and an outer cover or robe. The fillers or inner contents of the cigar must be of uniform quality and so packed and distributed in a longitudinal direction that the tobacco may burn uniformly and the smoke can be freely drawn from end to end. For the inner cover whole leaf of the same quality as the fillers is used, but for the outer cover only selected leaves of the finest quality and color, free from all injury, are employed. The covers are carefully cut to the proper size and shape with a sharp knife, and, being damped, a pile of them smoothed out are placed together. In making cigars by the hand, the operator rolls together a sufficient quantity of material to form the filling of one cigar, and experience enables him or her to select very uniform quantities. This quantity is wrapped in the inner cover, an oblong piece of leaf the length of the cigar to be made, and of width sufficient to enclose the whole material. The cigar is then rolled in the hand to consolidate the tobacco and bring it into proper shape, after which it is wrapped in the outer cover, a shaped piece made to enclose the whole in a spiral manner, beginning at the thick end of the cigar and working down to the pointed end, where it is dexterously finished by twisting to a fine point between the fingers. The finished cigars are either spread out in the sunlight to be dried, or, where that is impracticable, they are exposed to a gentle heat. They are then sorted into qualities according to their color, packed and pressed in boxes, in which they are stored for sale. Machinery is now employed for forming and moulding the fillings of cigars.

Havana cigars are, as regards form, classification, method of putting up, and nomenclature, the models followed by manufacturers of all classes of the goods. Genuine ("legitimas") Havana cigars are such only as are made in the island; and the cigars made in Europe and elsewhere from genuine Cuban tobacco are classed as "Havanas." Other brands of home manufacture contain some proportion of Cuban tobacco; and very good cigars may be made in which the name only of that highly-prized leaf is employed. When we come to the inferior classes of cigars, it can only be said that they may be made from any kind of leaf, the more ambitious imitations being treated with various sauces designed to give them a Havana flavor. The highest class of Cuban-made cigars, called "vegueras," are prepared from the very finest Vuelta Abajo leaf, rolled when it is just half dry, and consequently never damped with water at all. Next come the "regalias," similarly made of the best Vuelta Abajo tobacco; and it is only the lower qualities, "ordinary regalias," which are commonly found in commerce, the finer, along with the "vegueras," being exceedingly high-priced. The cigars, when dry, are carefully sorted according to strength, which is estimated by their color, and classed in a scale of increasing strength as *claro, colorado claro, maduro*, and *oscuro*. They are pressed into the cigar boxes for sale, and branded with the name or trade mark of their makers. Cheroots differ from ordinary cigars only in shape, being either in the form of a truncated cone, or of uniform thickness throughout, but always having both ends open and sharply cut across. Cheroots come principally from Manila, but there are now large quantities imported into the United Kingdom from the East Indies and Burmah.

Cigarettes.

Cigarettes consist of small rolls of fine cut tobacco wrapped in a covering of thin tough paper specially made for such use. Originally cigarettes were entirely prepared by the smoker himself; but, now that the consumption of cigarettes has attained gigantic proportions, especially in France, they are very largely made with the aid of an elaborate system of automatic machinery. The machines cut the paper, gum its edge, measure out the proper quantity of tobacco, wrap it up, make the gummed edge adhere, cut the ends, and pack the cigarettes in boxes.

Snuff.

The manufacture of snuff is the most complex, tedious, and difficult undertaking of the tobacco manufacturer; but it is an art now of relatively little and of decreasing importance. The tobacco best suited for snuff-making is thick fleshy leaf of a dark color, the finest qualities of snuff being made with dark Virginia leaf and the Amersfoort leaf of Holland; but manufacturers work up many kinds with fragments from the making of smoking tobacco, midribs, etc. The varieties and qualities of snuff are many, the differences being dependent on the material employed, the sauces with which it is treated, and the method of manufacture. The sauces for snuff consist of solutions of common salt, with various aromatic substances according to the flavor desired in the finished snuff, and with occasional additions of potash, sal-ammoniac, and other salts. The following is an outline of the method adopted in making snuff on the great scale in the state manufacture of France. The tobacco leaves are moistened with about one-fifth of their weight of salt and water (sp. gr. 1.089), made up into blocks, and piled in large rectangular heaps, in quantities of 40 or 50 tons. The temperature gradually rises to 140° F., and sometimes reaches 170°; but the heat must be regulated, or parts of the mass would become black as if charred. The heaps are made up in spring and autumn, and the fermentation is continued for five or six months, when the temperature remains stationary or begins to decline. The heap is then opened, and the tobacco is ground, by which means a pale brown dryish powder (*râpé sec*) is obtained. This is mixed with about four-tenths of its weight of a solution of common salt, and is passed through a sieve, that the powder may be uniformly moistened. It is then packed in large open chests in quantities of from 25 to 50 tons, where it remains for nine or ten months, and undergoes another fermentation, the temperature rising in the centre of the mass to 120° or 130°. During this process the snuff acquires its dark color and develops its aroma. But it is not uniform in quality throughout, and is removed to a second chest, in such a way as thoroughly to mix all the different parts together, and, after the lapse of two months, it is again turned over; and the process is sometimes repeated a third time. When the snuff is ripe, the contents of the various chests are mixed together in a large room capable of holding 350 tons of snuff, where it is left for about six weeks, and the whole mass being uniform in quality is sifted into barrels for the market. The process of manufacture occupies in all from eighteen to twenty months. During these repeated fermentations about two-thirds of the nicotine is destroyed, the acidity of the snuff disappears, and the mass becomes distinctly alkaline, notwithstanding that acetic acid is continuously evolved. The destruction of malic and citric acids continues, and the bases thereby set free saturate the acetic acid formed, leaving free ammonia in the snuff. The properties of snuff are dependent on the presence of free nicotine, free ammonia, and the peculiar aromatic principle developed in the fermentation.

The reduction of tobacco leaf to a snuff powder is a task of considerable difficulty, owing to the gummy nature of the substance, which tends to coat and clog grinding surfaces. In early times the duly sauced and fermented leaves were made up into "carottes,"—tightly tied up spindle-formed bundles, from the end of which the snuffer, by means of a "snuff rasp," rasped off his own supply, and hence the name "râpé," which we have still as "rappee," to indicate a particular class of snuff. The practice of tying up the leaves in the form of carottes is still followed by makers of fine stuff, as the very slow fermentation which goes on within the bundles is favorable to the development of a rich aroma. For pulverization, the leaves are first cut to shreds with a revolving knife, and then powdered either by a kind of mortar and pestle mill, or by falling stampers supplied with knife cutting edges, or more commonly they are treated in a conical mill, in which both the revolving cone and the sides have sharp cutting edges, so that the material undergoes a cutting rather than a grinding action. The snuff from the mill is sifted, and that which remains on the sieve is returned to the mill, the remainder being passed on as *râpé sec* for further treatment as described above.

Fiscal restrictions.

In nearly all civilized countries the cultivation of tobacco and its manufacture are conducted under state supervision, and form an important source of public revenue. In France, Austria-Hungary, Italy, and Spain the cultivation is a state monopoly, and in other countries the crop is subject to heavy excise duties. Since the time of Charles II. the growth of tobacco in England has been practically prohibited, the original legislative enactment to that effect having been passed with the view of encouraging trade with the young colony of Virginia. When that motive ceased to have force the supposed difficulties of collecting the internal taxation still influenced the legislature to continue their prohibition, and consequently a penalty or prohibitive tax equal to sixteen hundred pounds per acre is exigible on the cultivation of tobacco in the United Kingdom. In Ireland the duty on the cultivation of tobacco was abandoned between 1822 and 1830, and in that interval the cultivation grew till about a thousand acres were under the crop. In 1886 the government permitted the experimental cultivation of tobacco in England, under certain precautions and restrictions for the security of the revenue. Several proprietors in Kent, Norfolk, and other counties grew experimental patches with such success as to warrant the continuance of the experiment and to prove the entire practicability of cultivating tobacco as an English agricultural crop. The climate is, however, so variable that, were all restrictions removed, and tobacco grown subject only to excise supervision for collecting an equitable tax, it is more than doubtful whether its growth would be a safe and profitable undertaking.

Physiological effects.

The influence of tobacco on health and morals has, ever since its introduction into Europe, been a fruitful subject of controversy. On all grounds except as a medicine, it met the most uncompromising opposition when it first became known; but it was precisely the expectations entertained regarding its medicinal virtues which were completely disappointed. Burton, in the *Anatomy of Melancholy*, gives strong expression to the two views: "Tobacco, divine, rare, superexcellent tobacco, which goes far beyond all the panaceas, potable gold, and philosopher's stones, is a sovereign remedy in all diseases. A good vomit, I confess, a virtuous herb if it be well qualified, opportunely taken, and medicinally used; but, as it is commonly abused by most men, which take it as tinkers do ale, 'tis a plague, a mischief, a violent purge of goods, lands, health,—hellish, devilish, and damned tobacco, the ruin and overthrow of body and soul." Burton's meaning—that tobacco in moderation is a good thing, while its excessive use causes many physical and other evils—has many sympathizers; but the difficulty is to define moderation and excess. Among modern authorities, Dr. Jonathan Pereira says, "I am not acquainted with any well-ascertained ill effects resulting from the habitual practice of smoking." Similarly Sir Robert Christison concludes, "In many individuals who use it habitually, the smoke has an extraordinary power in removing exhaustion, listlessness, and restlessness, especially when brought on by bodily or mental fatigue, and this property is the basis of its general use as an article of luxury." Dr. E. A. Parkes sums up his observations thus: "I confess myself quite uncertain. I can find nothing like good evidence in books; too often a foregone conclusion, without any evidence to back it, is given. I think we must decidedly admit injury from excess; from moderate use I can see no harm, except it may be in youth." On the other hand, it is asserted by the opponents of tobacco, and by the anti-tobacco societies, that the habitual use of this narcotic leads, especially in the young, to decrease of bodily and mental vigor, and specially produces symptoms of anæmia, palpitation, intermittent pulse, and other affections of the heart and circulation. It is an admitted fact that a disease of the vision—tobacco amblyopia—is contracted by smokers, and is not uncommon among those using strong heavy preparations, such as black twist. Allowing that such incidental evils may arise from even comparatively moderate indulgence in tobacco, they are after all as nothing compared to the vast aggregate of gentle exhilaration, soothing, and social comfort, extracted from the Virginian weed.

Commerce.

With the almost universal prevalence of the use of tobacco, it must be obvious that the amount consumed yearly is very great. In the United Kingdom, which is much less a tobacco consuming country than the United States or many European countries, the consumption per head has steadily increased, as is shown in the accompanying table.

	Total Consumption.	Per Head.
	℔.	oz.
1821	15,598,152	11.71

The customs duty derived from imports of tobacco amounted in 1886 to £9,298,990 [$45,193,091.40], and there certainly is a considerable quantity of manufactured tobacco smuggled into the kingdom which comes into no official record. In the United States the production of tobacco was in 1840 219,163,319 ℔, in 1850 199,752,655 ℔, in 1860 434,209,461 ℔, in 1870 262,735,341 ℔, and in 1880 472,661,157 ℔. During the ten years ending 1881 the average annual production was 472,000,000 ℔, cultivated on from 600,000 to 700,000 acres, the value of the crops ranging from $40,000,000 to $45,000,000. In the same ten years 2,540,818,001 ℔ of leaf were exported, 1,897,606,249 ℔ were manufactured for home consumption, and the quantity consumed by growers was estimated to be equal to 280,000,000 ℔.

For Tobacco Pipe, see PIPE.

The literature of tobacco is very extensive. The late Mr. William Bragge of Birmingham published in 1880 a revised bibliography of the subject, *Bibliotheca Nicotiana*, extending to 248 quarto pages. From such a mass of authorities it would be vain here to make selections, but mention may be made of Fairholt's capital gossiping work, *Tobacco, its History and Associations* (2d ed., 1876). As modern standard works there may also be quoted Tiedemann's *Geschichte des Tabaks* (1856) and Wagner's *Tabakcultur, Tabak- und Cigarren-Fabrication* (1884). In the Tenth Census Report of the United States (1883), vol. iii., there are a series of elaborate papers on the cultivation, manufacture, and statistics of American tobacco. (J. PA.—W. D.)

TOBAGO, the most southerly of the Windward group of British West Indian Islands (11° 9′ N. lat., 60° 12′ W. long.), 20 miles northeast from Trinidad, is 26 miles in length and 7½ at its greatest breadth, with an area of 114 square miles (73,313 acres). Its formation is volcanic, and the physical aspect irregular and picturesque, with conical hills and ridges; the main ridge is 1800 feet high and 18 miles long. There are several excellent harbors. The products are sugar, rum, molasses, and fruits of various kinds, only the low ground being cultivated; production is not increasing. In 1885 the revenue was £10,826 [$52,614.36] and the expenditure £12,031 [$58,470.66],[1] while the imports were £30,758 [$149,483.88], and the exports £26,414 [$128,372.04]. The population in 1885 was 19,363

(9368 males and 9995 females), principally of African race, the whites being very few. Tobago has a small legislative council and an administrator under the Government of the Windward Islands. Its capital is Scarborough (1200 inhabitants), on the southeast coast.

Tobago was discovered by Columbus in 1498, and the British flag was first planted in 1580, the island being then occupied by Caribs. It has subsequently been held by the Dutch and the French, but ultimately was ceded to the British crown in 1814.

TOBIT, The Book of, one of the Old Testament apocrypha, relates with many marvellous circumstances the virtues, trials, and final deliverance of Tobit, a pious Israelite who was carried to Nineveh in the captivity of the ten tribes, and, after rising into favor and wealth as a trader at the royal court, was reduced to poverty because he habitually buried those of his nation whom the tyrant slew and ordered to be cast forth unburied. Besides this he lost his eyesight through an accident. Reduced almost to despair, like Job, and taunted like Job by his wife ("where are thy alms and righteous deeds?"), he yet puts his faith in God and prepares to die, but first resolves to send his son Tobias to Rhagæ (Rai), in Media, to reclaim an old loan. Now his prayers are heard and his righteousness rewarded, for Raphael, one of the seven angels that present the prayers of the saints before God, is sent in human form to conduct Tobias on his journey. Thus aided Tobias not only recovers his father's money, but by killing a fish which attacks him as he washes his feet in the Tigris, becomes possessed of two invaluable drugs, its liver with the heart and its gall. By fumigation with the former he drives away the demon Asmodeus, who had slain the seven bridegrooms of a virtuous Jewish maiden, Sara of Ecbatana, his own kinswoman, and so wins a good wife, and with the gall he heals his father's eyes. In spite of the absurd machinery and other puerilities, the story is ingeniously constructed, and the picture of Tobit's piety is natural and touching, so that the whole is a very good exhibition of the weakness and the strength of Judaism as it was among the Israelites of the dispersion.

The date of the book cannot be precisely determined. It was written before the destruction of the temple (xiv. 5), and is cited by early Christian writers. On the other hand, it is in the highest degree probable that the Greek text is original,[1] in which case the book can hardly be earlier than the 2d century B.C. A date about the middle of this century, or a little earlier, at the time of bitter conflict with the Greeks, seems to accord best with the tone of the book. The sympathy shown for the victims of tyranny, to whom burial was denied, acquires fresh meaning when compared with such a passage as 2 Mac. v. 10, and the prominence given to eschatological hopes in the closing verses fits a time when interest in the prophecies of Israel's future glory was revived by the struggle for national independence in Judæa.

That Tobit was written by a Jew of the Eastern dispersion (so *e.g.*, Ewald, *Gesch.*, iv. 269) will hardly be maintained by any one who accepts the Greek text as original. The book remained almost unknown to the Syriac church, a fact which tells strongly against the hypothesis of an Eastern origin; and at the period to which the work can be best referred Egypt is the only probable place for a Jewish-Greek composition. The writer knows nothing about the geography of the East beyond a few names which every Jew must have heard,—the Tigris, which by an error common among the Greeks but hardly possible to an Oriental Jew, he regards as flowing between Nineveh and Media; Rhagæ, which was a royal residence of the Parthians; the famous city of Ecbatana; and Elymais (ii. 10), which was associated with the disaster of Antiochus Epiphanes. And in both forms of the Greek text (vi. 9 in the common text and v. 6 in the longer) Rhagæ is falsely represented as quite near Ecbatana.[2] Nöldeke surmises, as others have done before him, that the "fish" which attacked Tobias was the Egyptian crocodile, and this conjecture is raised almost to certainty when we read in Ḳazwini i. 132 that the smell of the smoke of crocodile's liver cures epilepsy, and that its dung and gall cure leucoma, which was the cause of Tobit's blindness.[3] Thus the cures of Sara and Tobit are natural (*cf.* the longer Greek text, vi. 4 *sq.*); the angel's help is necessary only to secure the medicaments and explain their use.

But though the story may have been written in Egypt it contains Persian elements. There is no inconsistency in this, for the authors of Jewish Haggada generally borrowed the themes which they embellished, and that from very various quarters. In fact, at the close of our book there is a brief allusion to another story,[4] quite unknown to us, which the author evidently did not invent. The proof of a Persian element in the tale lies, not in the localities, but in the angelology and demonology. Asmodeus is the Iranian evil spirit Aeshmâ Daevâ, and Raphael as the guardian of Tobias, has a strong resemblance to the Iranian Çraosha. Such precise adaptations of Zoroastrian ideas were hardly the common property of Judaism at so early a date; they lead us to conjecture that the writer borrowed from an Iranian story.[5] And only in this way can we explain the appearance of the dog who goes out and returns with Tobias and Raphael. This trait is so inconsistent with Jewish feelings towards the unclean animal that it is omitted in the Hebrew and Chaldee versions. But to the Iranians the dog was not only a sacred animal, the protector of herds and homes, but was the companion of the protecting spirit Çraosha (*Bundahesh*, chap. xix.), to whom Raphael in our tale corresponds.

The Greek text of Tobit is found in a shorter recension (the usual text) and in a longer form preserved in the Codex Sinaiticus (published by F. H. Reusch, 4to, Bonn, 1870). There are fragments of another form of the longer text in several cursives. All the forms are given in Fritzsche's *Libri Apocryphi*, Leipsic, 1871. The shorter text, in the judgment of Fritzsche and Nöldeke, is the earlier. The longer text is also represented by the Latin versions, the second part of the rare Syriac version (the first part is from the hexaplar Greek), and two closely allied Jewish versions, the Aramaic (published by Neubauer, from a unique Midrash in the Bodleian, Oxf., 1878) and the Hebrew, first printed in Constantinople (1516), reprinted by Münster in 1542 (whence its common name *Hebræus Munsteri*) and included in Neubauer's edition. The Aramaic seems to be a late form of the text known to Jerome, and of which he made use for the Vulgate Latin; it is certainly a translation from the Greek. There are recent commentaries on Tobit by Fritzsche (*Kurzgef. Handb. zu den Apocr.*, ii., Leipsic, 1853). Reusch (Freiburg, 1857), Sengelmann (Hamburg, 1857), and Gutberlet (Theissing, 1877). Nöldeke's paper already quoted is indispensable. For other literature, see Schürer, *NTliche Zeitgesch.*, ii. 609. (W. R. S.)

TOBOLSK, a government of Western Siberia, having the Arctic Ocean on the N., Archangel, Vologda, Perm, and Orenburg on the W., Akmolinsk and Semipalatinsk on the S., and Tomsk and Yeniseisk on the E., is one of the largest provinces of the Russian empire, occupying nearly 7 per cent. (531,980 square miles) of its total area. It borders on the Arctic Ocean,

[1] See the arguments of Nöldeke, *Monats. Berl. Ak.*, 1879, p. 45 *sq.* This paper also contains the best discussion of the relation of the various texts of the book.

[2] Nöldeke shows that the same error in a less gross form appears in both texts in chap. ix. The further erroneous statement of the longer text that Ecbatana lies in a plain occurs also in Diod., ii. 13, 6, in a passage dependent on Ctesias, from whom the addition may have been taken.

[3] Very similar statements as to the medical virtues of the crocodile (aquatic or terrestrial) occur in Greek and Latin writers.

[4] The story of Nadab and Achiacharus. The names are uncertain, and one text substitutes Aman (Haman) for Nadab. But the allusion is not to the book of Esther.

[5] Compare what is said under THOUSAND AND ONE NIGHTS (p. 337) as to the probable influence of an Iranian legend on the book of Esther.

from the river Kara to the Bay of the Ghida, the broad peninsula of Yałmał projecting between the Kara Sea on the west and the Bay of the Ob; this last penetrates into the continent for more than 550 miles, with a width of from 60 to 70 miles, and receives another long and wide outlet—the bay of the Taz (Tazovskaya). Another wide bay of the Kara Sea—the Baidaratsk, or Kara Bay—runs up into the Yałmał peninsula from the northwest. The islands belonging to the government are few; Byelyi, at the extremity of Yalmal, and a few small ones along the west coast of the peninsula, as also in the Obi Bay, are for the most part ice-bound. This extensive province occupies the greater part of the lowlands of northwestern Asia, which extend eastward from the Urals, and only in the far north does it include the eastern slopes of these mountains. The Pai-ho coast-ridge only touches Tobolsk with its southeastern extremity. The Urals proper which run southwest from the Kara Sea as far as to the Tell-pöss group (5540 feet), and thence take a southerly direction, form the boundary between Tobolsk and Vologda as far as the scources of the Petchora (61° 30′ N. lat.), but farther south their eastern slopes are included in the Russian government of Perm, and only their lowest spurs, 200 miles from the main ridge, belong to Tobolsk. The average height of the northern Urals is about 3000 feet, and several of their summits range from 3300 to 4000 and even 4370 feet (Net-yu, in 68° N. lat.). The remainder of the government is of lowland character, hardly at any point rising above the sea by more than a few hundred feet, but these lowlands vary greatly in their different parts. They assume the character of grassy steppes or prairies in the south, of immense marshes sparsely covered with forest in the north, and of treeless tundras as the shores of the Arctic Ocean are approached. The southern steppes, in their turn, may be subdivided into two distinct portions,—the Toboł and Ishim steppe in the west, and the Baraba in the east. The former, nearly 43,000 square miles in area, is one of the most fertile parts of the empire. One-third is under forest, and the remainder has a soil of very fertile black earth, which has the further advantage of being sufficiently watered. The climate, indeed, is very severe, the mean annual temperature (30° to 34° F.) being such as is found only in the north of Sweden and in Archangel; but the warm summer (65° to 68° in July) and the amount of light received from a bright sky combine to make vegetation develop with a rapidity quite unknown to western Europe. This region now has a population of more than 800,000, almost all Russians (only 14,000 aborigines), so that it may be said to be more thoroughly Russian than the Volga provinces. The area under crops every year is 3½ million acres, and the region promises to become a regular granary for Siberia and northeastern Russia. The second portion of the southern plains, which might be called the Baraba region, being mostly occupied by the Baraba steppe, covers about 55,000 square miles. Only its western borders belong to Tobolsk. It also is perfectly flat, and covered with recent deposits; but, as there is no definite slope, the surface waters move slowly, and accumulate into a very large number of lakes and marshes. The climate is moister and the summer still shorter and less hot than in the preceding region. Forests, consisting chiefly of birch, are spread in clusters over its surface. The soil of this region also is very productive, but the fertile patches are separated by marshy grounds, and the dense clouds of mosquitoes which float over it in summer are a positive plague to both man and beast. The population numbers only 250,000, also almost all Russians (only 4000 aborigines), and the area annually under crops is about 1,350,000 acres. To the north of the regions just specified is that occupied by the administrative districts of Tura, Tobolsk, and Tara, with an area of about 110,000 square miles; this may be described as the *taiga* region. It is covered throughout with impenetrable forests and quivering marshes —the dreadful *urmans*, which are penetrated by man only for some 20 to 50 miles around the widely separated settlements. Immense cedar-trees, larches, firs, pines, birches, and maples grow very densely, and the underwood is so thick that a passage can be forced only with the aid of the hatchet, the difficulties being further increased by the layers of decayed wood and by the marshes. To cross these, which are treacherously concealed under a swaying layer of grassy vegetation, a kind of snow-shoe must be used even in the summer, and many can be crossed only in winter. Immense areas of the *urmans*, especially on the Vasyugan, have never been visited by man; but still, from time to time a Russian settlement arises in the forests, mostly founded by Nonconformists in hiding, who freely receive all sorts of fugitives. The southwestern parts of this region are crossed by the Siberian highway, and to this circumstance alone is it indebted for its population of nearly 450,000 (32,000 aborigines). Only 2 per cent. of this area is under culture. Farther north extend the tundras, where the average temperature rapidly decreases from the 25° F. found in the preceding region to 15°, 10°, and 7°. The frozen soil during the hottest part of the summer thaws only for a few inches beneath the surface. The frost sets in early, and a thick envelope of snow lowers the spring temperature. Forests cover the southern parts, but the trees become poorer, shorter, and thinner, and huddle into impenetrable thickets; while, farther north, only the creeping variety of birch and the dwarf varieties of willow hold their ground. Within the Arctic Circle the last traces of arboreal vegetation disappear, their northern limit being pushed south by the double bay of the Ob and the Taz, and by the proximity of the Kara Sea.

Apart from the Urals, there are no traces of hard rock anywhere in Tobolsk. Down to its southern borders it is covered with Post-Pliocene deposits, which are met with as far as the water-parting between the Irtish and the Aral-Caspian depression. This range of flat hills rises a few hundred feet above the sea-level, and it seems to mark the limit of extension of the Post-Glacial gulf of the Arctic Ocean which covered western Tobolsk during the Glacial period. Contrary to Humboldt's hypothesis, it remains, however, doubtful whether it was connected in Post-Glacial times with the Aral-Caspian Sea otherwise than by means of narrow straits, which disappeared at any rate at an early stage in that geological period.

The climate of Tobolsk is one of great extremes, the differences between the averages for the hottest and coldest months reaching as much as 70° F. The average temperatures at Berezoff, Narym, Tobolsk, and Ishim respectively are 24°, 28°, 31.8°, and 32° (January, —8.3°, —8°, —2°, and —4°; July from 62° to 67°). Only 194 days at Ishim and 153 at Berezoff have a temperature above 32°; and the Ob at Obdorsk continues ice-bound for 219 days (the Irtish 176 days at Tobolsk).

The government is watered by the Ob, which traverses it for more than 1300 miles, and is navigable throughout. It receives many tributaries, some of which are 200 to 350 miles long, but flow through quite uninhabited regions. The Irtish, a left-hand tributary of the Ob, covers all the southern part of Tobolsk with its numerous tributaries. It waters Tobolsk for 760 miles, and is navigable for the whole of its length; it receives the great Toboł, about 420 miles long, also navigable, the Ishim, and a number of less important streams; while the Tura, a tributary of the Toboł, is also a channel for navigation. The navigation lasts for nearly six months in the south. The first steamer on the Ob system was launched in 1845 and the second in 1860; since the latter date steam navigation has steadily developed.

Lakes, some of them salt, occur in great numbers on the water-parting between the Irtish and the Aral-Caspian, and everywhere in South Tobolsk. Lake Tchany, the largest, covers 1265 square miles. All are being rapidly dried up, and even within the last hundred years they have undergone great changes. Thus, in the group of lakes of Tchany, in the Baraba steppe, whole villages have arisen on ground that was under water in the earlier years of this century.[1] Immense marshes cover Tobolsk beyond 57° N. lat.,—the

---

[1] See Yadrintseff in *Izvestia Russ. Geogr. Soc.*, 1886.

Vasyugan marshes in the east, the Koudinsk and Berezovsk marshes in the west, both joining farther north the tundras of the Arctic shores.

The population reached 1,283,000 in 1882. Although recent immigrants, the Russians already constitute 94 per cent. of the aggregate population, and their numbers are steadily increasing by immigration, and partly also by the arrival of exiles. No fewer than 43,750 immigrants from Russia settled at Tobolsk between 1846 and 1878, but of late this figure has greatly increased. In 1879 as many as 59,134 exiles were on the registers, but of these more than 20,000 had left their abodes and disappeared. As a rule the exiles belong to the poorest class of population. According to M. Yadrintseff,[1] the native population of Tobolsk was represented in 1879 by 29,150 Tartars and 8730 other Turkish inhabitants, chiefly in the south, 22,350 Ostiaks, chiefly on the Ob, 6920 Samoyedes in the north, and 6100 Voguls in the northwest; the total amounted to 74,220,—that is 6.1 per cent. of the aggregate population (1,206,000 in 1879). The OSTIAKS (*q.v.*) are in a very miserable condition, having come under heavy obligations to the Russian merchants, and being compelled to hand over to them nearly all the produce of their hunting and fishing. The Tartar settlements in the south are prosperous, but not in the Tobolsk district, where their lands have been appropriated for the Russian settlers. Of the Russians nearly 35,000 are Nonconformists, according to official figures, but the number is greatly understated. Many of the Samoyedes, Ostiaks, and Voguls are nominally Christians. The Russians and the Tartars, who chiefly inhabit South Tobolsk, mostly live by agriculture. Of the total area of land regarded as suitable for cultivation (28,400,000 acres), 15,600,000 are owned by the peasant communities. Summer wheat, rye, oats, barley, and some buckwheat are raised. Flax and hemp and tobacco are cultivated in the south, where cattle-breeding also is extensively carried on. The ravages of anthrax, however (see MURRAIN, vol. xvii. p. 64), are very severe, especially in the marshy parts of the province. The indigenous inhabitants of the north had, in the same year, more than 100,000 reindeer. Dogs are used in sledges in the far north. In the forest region the chief means of existence are found in the forests. The pursuit of bears, wolves, foxes, squirrels, ermines, stags, elks, as also of sables and beavers (rapidly disappearing), is a regular occupation with the Russian peasants as well as with the indigenous inhabitants; sledges and cars, mats, sieves, wooden vessels, and pitch and tar are also manufactured to a considerable extent in the villages (valued at about £150,000 [$729,000]). Cedar-nuts (from 5000 to 8000 cwts. every year) are gathered, partly for the sake of their oil. The fisheries of the Ob and the southern lakes are important; no fewer than 1700 Ostiaks are engaged in them on the Ob. No less than 200,000 cwts. of fish are annually caught in the district of Tara alone, and Surgut exports it to the value of £10,000 [$48,600], while in the Narym region 10,000 cwts. of salt are used for preserving the fish.

The industries are insignificant (chiefly tanning, distilling, and tallow-melting); iron-works and woollen cloth mills are still in their infancy. The export of cattle, hides, tallow, corn, flour, fish, and furs to Russia, both from Tobolsk and from the Kirghiz steppe, is of some importance. Spirits are sent farther east, to Tomsk; while all kinds of manufactured wares are imported from Russia. The fairs of Irbit and Ishim are the chief centres for trade.

The educational institutions are few. It is worthy of remark that of "secondary schools" (gymnasia and progymnasia) there were in 1883 eight for girls, with 1065 scholars, and only four for boys, with 711 scholars; of primary schools there were 250, with 5844 boys and 1403 girls.

Tobolsk is divided into ten districts (*okrugs*), the chief towns (with populations in 1883) being Tobolsk (20,130), Berezoff (1990), Ishim (7100), Kurgan (8570), Surgut (1460), Tara (8640), Turinsk (4650), Tyukałinsk (3900), Tyumeñ (14,300), and Yalutorovsk (4500). Of these towns only TOBOLSK and TYUMEÑ (*q.v.*) are really entitled to the designation, the others being mere villages, of less importance than many others on the great Siberian highway which crosses the government from Tyumeñ to Tomsk.

(P. A. K).

TOBOLSK, capital of the above government, is situated on the right bank of the Irtish, near its junction with the Toboł. It is 1535 miles from Moscow, and since the alteration of the course of the great Siberian highroad from Tyumeñ to Tomsk it has become an out-of-the-way place, and is no longer either capital of Western Siberia or even an administrative centre for exiles, as it was formerly. Viewed from the Irtish, the town has a picturesque aspect, with its kreml, or stone walls, built on a crag 200 feet high, its twenty-one churches, and several elegant buildings. The kreml, built under Peter I. by Swedish prisoners, in imitation of the kreml of Moscow, is 430 yards long by 200 yards in breadth, and contains two cathedrals erected towards the end of the 17th century. The bell of Uglitch, which rang the alarm when the czarevitch Dmitri was assassinated by order of Boris Godunoff, and therefore had its "ear torn away," and was exiled to Siberia, stands close by. The palace of the governor, the administrative offices, the seminary where the historian of Siberia, Slovtsoff, received his education, the gymnasium where Mendeléeff the chemist was trained, and the Marie school for girls, which now supplies Siberia with so many teachers, are in the upper part of the town, where broad grassy spaces separate the wide streets paved with thick planks. A monument to Yermak, the rebel Cossack who conquered Siberia, stands in a prominent place; and one of the sides of the large square on the crag is occupied by the immense prison, where more than 2000 exiles are gathered during the period of navigation. The lower part of the town stands on a sandy beach of the Irtish, and often suffers from floods. Its sanitary condition is very bad. The merchants of Tobolsk carry on a fairly brisk trade in corn from the south, salt from Semipalatinsk, timber and fish from the lower Ob. The population is almost stationary (20,130 in 1883, as against 15,500 in 1839 and 15,200 in 1772). Some 12 miles to the southeast are the ruins of the "fort of Kutchum,"—the seat of the capital of Siberia, Isker, before the Russian conquest.

Tobolsk was founded in 1587 by 500 Cossacks who left Tyumeñ under Tchulkoff, and built a wooden fort at the mouth of the Old Toboł. During the next fifteen years several other forts were erected on the territory now occupied by Tobolsk. The Ostiaks and Samoyedes soon submitted to Russian rule, but the Tartars and Bashkirs made frequent raids, so that a line of forts had to be built in the 17th century from Orenburg to Ishim. In 1752 a new line of forts was erected some 150 miles farther south, and since that time Russian settlers have been able quietly to colonize the most fertile parts to the south of Tobolsk.

TOCQUEVILLE, ALEXIS HENRI CHARLES CHÉREL, COMTE DE (1805–1859), was born at Verneuil on July 29, 1805. His family on the father's side were of good descent, and distinguished both in the law and in arms, while his mother was the granddaughter of Malesherbes. Alexis de Tocqueville was brought up for the bar, or, rather, according to the division of that profession in France, for the bench, and became an assistant magistrate in 1830. A year later he obtained from the Government of July a mission to examine prisons and penitentiaries in America, and proceeded thither with his lifelong friend Gustave de Beaumont. He returned in somewhat less than two years, and published a report on the subject of his mission, but the real result of his tour was the famous *De la Démocratie en Amérique*, which appeared in 1835, and very soon made his reputation. It was at once caught up by influential members of the Liberal party in England, which country Tocqueville soon after visited, and where he married an Englishwoman. Returning to France, and beginning life as a country gentleman at Tocqueville, he thought to carry out the English ideal completely by standing for the chamber of deputies. But, with a scruple which illustrated his character, he refused Government nomination from Molé, and was defeated. Later he was successful, and sat for several years both before and after the revolution of February, becoming in 1849 vice-president of the assembly, and for a few months minister of foreign affairs. He was a warm supporter of the Roman expedition, but an equally warm opponent of Louis Napoleon, and after being one of the deputies who were arrested at the *coup d'état* he retired from public life. Twenty years after his first, he produced another book, *De l'Ancien Régime*, which almost, if not quite, equalled its success. His health was never very strong, and in 1858 he broke a bloodvessel. He was ordered to the south, and, taking up his residence at Cannes, died there on the 16th of April, 1859. He had published some minor pieces during his lifetime, and his complete works, including much unpublished correspondence, were produced after his death in uniform shape by De Beaumont.

---

[1] *Siberia as a Colony* (Russian).

During the last twenty years of his life, and for perhaps half that time after his death, Tocqueville had an increasing European fame, which for the last ten or fifteen years has been stationary if not diminishing. Both phenomena are susceptible of explanation. Although he has been accused by some of his own countrymen of having "le style triste," his manner, which is partly imitated from Montesquieu, has considerable charm; and he was the first and has remained the chief writer to put the orthodox liberal ideas which governed European politics during the first half or two-thirds of the 19th century into an orderly and attractive shape. He was, moreover, as has been said, much taken up by influential persons in England,—Senior, John Stuart Mill, and others,—and he had the great advantage of writing absolutely the first book of reasoned politics on the facts of democratic government as observed in America. Besides all this he was, if not an entirely impartial writer, neither a fanatical devotee of democracy nor a fanatical opponent of it. All this gave him a very great advantage which he has not yet wholly lost. At the same time he had defects which were certain to make themselves felt as time went on, even without the alteration of the centre of liberal opinion which has taken place of late years. The chief of these was a certain weakness which can hardly be described in English by any word more dignified than the familiar term "priggishness." His correspondence with Molé above alluded to is an instance of this, and it was also reflected on in various epigrams by countrymen and contemporaries; one of these accuses him of having unluckily "begun to think before he had begun to learn," while another, with more real than apparent inconsistency, declares that he "avait l'air de savoir de toute éternité ce qu'il venait d'apprendre." His book on America, though undoubtedly a very remarkable piece of political deduction, has the drawback of proceeding on very insufficient premisses and of trying to be too systematic. His book on the *Ancien Régime* is also wanting in solid information, and commits the great error of assuming rather than proving that the Revolution of 1789 was a proceeding of unmixed good, which delivered France from a state (not of unmixed evil, for Tocqueville was too careful a student to imagine that, but) of evil exclusively caused by the existence of monarchical and aristocratic institutions. In fact, the fault of both books is that their author is not a practical politician, a fault which is constantly illustrated and exhibited in his correspondence. He appears both in reading history and in conducting actual political business (of which, as has been seen, he had some experience) to have been constantly surprised and disgusted that men and nations did not behave as he expected them to behave. This excess of the deductive spirit explains at once both the merits and defects of his two great works, which will probably remain to some extent political classics, though they are less and less likely to be used as practical guides.

TODAS. See Nílgiri Hills, vol. xvii. p. 522.

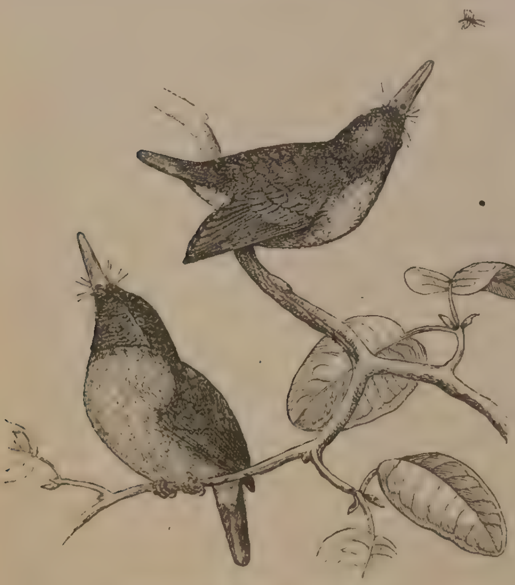
TODLEBEN, or TOTLEBEN, EDUARD IVANOVICH (1818–1884), Russian general, was born at Mittau, in Courland, on May 20, 1818. His parents, who seem to have been of German descent, were of the mercantile class, and he himself was intended for commerce, but a strong instinct led him to seek the career of a military engineer. He entered the school of engineers at St. Petersburg in 1835, and passed from that into the army in 1838. In 1847 and the two following years he was employed, as captain of engineers, in the campaigns against Schamyl in the Caucasus, where he directed the siege operations against the principal mountain fortresses. On the outbreak of war between Russia and the Porte in 1853, he was placed at the head of the staff of General Schilder-Schuldner, by whom Silistria was besieged. This general being wounded, Todleben acted in his place until the siege was raised. He was then transferred to the Crimea. Sebastopol, while strongly fortified toward the sea, was almost unprotected on the land side. Todleben, though still only of colonel's rank, became the animating genius of the defence. By his advice the fleet was sunk, in order to blockade the mouth of the harbor, and the deficiency of fortifications on the land side was made good before the allies could take advantage of it. The construction of earthworks and redoubts was carried on with extreme rapidity, and to these was transferred, in great part, the artillery that had belonged to the fleet. In whatever direction the besiegers drew their lines, there Todleben met them with counterworks, until, with the arrival of heavy Russian reinforcements, the besiegers almost became the besieged. It was in these improvised operations by means of earthworks that Todleben's peculiar power and originality showed itself; he was not a great military leader in the wider sense, nor was he the creator of a great permanent system of defence like Vauban. But for the special problems of Russian warfare, both in 1854 and at a later epoch, he was exactly the man wanted. Until June, 1855, he conducted the operations of defence at Sebastopol in person; he was then wounded in the foot, and at the operations which immediately preceded the fall of the fortress he was not present. When he recovered from his wounds he was employed in strengthening the fortifications at the mouth of the Dnieper, and also those of Cronstadt. In 1856 he visited England, where his merits were well understood. In 1860 he was appointed assistant to the grand-duke Nicholas, and he became subsequently chief of the department of engineers. For reasons which are not known he was given no command when war with Turkey began in 1877. It was not until the disasters before Plevna had heaped discredit upon the incompetent leaders of the Russian army that the soldier of Sebastopol was called to the front. Todleben saw that Plevna could not be taken by assault, and that it would be necessary to reduce it by drawing works round Osman Pasha, and cutting him off from communication with the other Turkish commanders. In due time Plevna fell. Todleben then undertook the siege of the Bulgarian fortresses. After the conclusion of preliminaries of peace, he was placed in command of the whole Russian army, and became responsible for the government and administration of the occupied districts. In the discharge of these duties he is said to have distinguished himself by his combined firmness and good temper in dealing both with Turkish authorities and with the native population. He received the highest military honors and commands when the war was over, and became governor of Odessa. But his health was broken; and after much suffering he died at a German watering-place in June, 1884. He was buried with great solemnity at Sebastopol.

TODMORDEN, a market-town of England, partly in Lancashire but chiefly in the West Riding of Yorkshire, stands on the Calder, on the Rochdale Canal, and on the Lancashire and Yorkshire Railway, 13 miles west of Halifax, 9 north of Rochdale, and 207¼ north-northwest of London. It lies in three valleys amidst scenery originally romantic, and still in part retaining that characteristic. The town-hall (1875) bridges the counties boundary, the Calder, enabling the magistrates to exercise jurisdiction in both counties. Of the other buildings, the Unitarian church, the market-hall, the free endowed school, and the Unitarian free school may be mentioned. A bronze statue has been erected to John Fielden, to whose energy in developing the cotton manufacture the town owes much of its prosperity. The staple industry is the spinning and weaving of cotton, and there are also foundries and machine-works. The population of the township of Todmorden and Walsden (area 7007 acres) in 1871 was 9333, and in 1881 it was 9237. In addition to this (situated wholly in Yorkshire), the urban sanitary district includes parts of Langfield and

Stansfield in Yorkshire, and of Cliviger in Lancashire, the total area being 15,690 acres, with a population in 1871 of 21,764, and in 1881 of 23,862.

As early as the reign of Edward III. Todmorden was in the possession of the Radcliffes, a branch of the Radcliffes of Radcliffe Tower, but it was sold by them about the close of the 17th century. Todmorden Hall is an interesting old building of various dates.

TODY, Pennant's rendering (*Gen. Birds*, pp. 15, 61) through the French *Todier* of Brisson (*Ornithologie*, iv. p. 528) of the somewhat obscure Latin word *Todus*,[1] not unhappily applied in 1756 by Patrick Browne (*Civ. and Nat. Hist. Jamaica*, p. 476) to a little bird remarkable for its slender legs and small feet, the "Green Sparrow" or "Green Humming-Bird" of Sloane (*Voyage*, ii. p. 306). The name, having been taken up by Brisson (*loc. cit.*) in 1760, was adopted by Linnæus, and has since been recognized by ornithologists as that of a valid genus, though many species have been referred to it which are now known to have no affinity to the type, the *Todus viridis* of Jamaica, and accordingly have since been removed from it. The genus *Todus* was at one time placed among the *Muscicapidæ* (*cf.* FLYCATCHER, vol. ix. p. 307); but Dr. Murie's investigations (*Proc. Zool. Society*, 1872, pp. 664–680, pl. lv.) have conclusively proved that it is not Passerine, and is nearly allied to the *Momotidæ* (*cf.* MOTMOT, vol. xvii. p. 9) and *Alcedinidæ* (*cf.* KINGFISHER, vol. xiv. pp. 83–84), though it should be regarded as forming a distinct Family *Todidæ*, peculiar to the Greater Antilles, each of which islands has its own species, all of small size, the largest not exceeding four inches and a half in length.



Tody (*Todus viridis*). (After Gosse.)

Of the species already named, *T. viridis*, Mr. Gosse (*B. Jamaica*, pp. 72–80) gives an interesting account. "Always conspicuous from its bright grass-green coat and crimson-velvet gorget, it is still a very tame bird; yet this seems rather the tameness of indifference than of confidence; it will allow a person to approach very near, and, if disturbed, alight on another twig a few yards distant . . . commonly it is seen sitting patiently on a twig, with the head drawn in, the beak pointing upwards, the loose plumage puffed out, when it appears much larger than it is. It certainly has an air of stupidity when thus seen. But this abstraction is more apparent than real; if we watch it, we shall see that the odd-looking gray eyes are glancing hither and thither, and that ever and anon the bird sallies out upon a short, feeble flight, snaps at something in the air, and returns to his twig to swallow it." Mr. Gosse goes on to describe the engaging habits of one that he for a short time kept in captivity, which, when turned into a room, immediately began catching all the insects it could, at the rate of about one a minute. The birds of this Family also show their affinity to the Kingfishers, Motmots, and Bee-eaters by burrowing holes in the ground[2] in which to make their nest, and therein laying eggs with a white translucent shell. The sexes differ little in plumage.

All the four species of *Todus*, as now restricted, present a general similarity of appearance, and, it may be presumed, possess very similar habits. The genus has been monographed by Mr. Sharpe (*Ibis*, 1874, pp. 344–355); but he was unfortunately misled by an exceptionally bright-colored specimen to add a fifth and bad species to those that exist—and even these, by some ornithologists, might be regarded as geographical races. The Cuban form is *T. multicolor*; that of Hispaniola is *T. subulatus* or *dominicensis*; and that of Porto Rico, originally named in error *T. mexicanus*, has since been called *hypochondriacus*. Apart from their structural peculiarities, one of the chief points of interest attaching to the *Todidæ* is their limitation, not only to the Antillean Sub-region, but, as is now believed, to its greater islands. (A. N.)

TOGA. See COSTUME, vol. vi. p. 403.

TOGO-LAND, one of the portions of the African continent under the protection of the German empire. It forms part of the territory on the west coast formerly distinguished as the Slave Coast, and is bounded on the E. by Little Popo, on the S.W. by the British Gold Coast Colony, and on the N.W. by the still independent territory of the Anlo tribes. The coast-line is only 22 miles in length, and with an area of about 500 square miles Togo-land is estimated to have a population of 40,000 souls. The great physical feature of the country is the Togo, Hakko, or Avon lagoon, which is cut off from the ocean by the narrow belt of sandy soil on which are situated Bagida, Porto Seguro, and Bay. The town of Togo lies on the east side of the Togo lagoon, where it extends eastward to Little Popo Lake. The lagoon is fed by a stream from the north, the Haho or Hakko, first discovered by John Duncan in 1846.

See Hugo Zöller, *Togoland; Petermann's Mittheilungen* (1886); and *Scott. Geogr. Mag.* (1886), all of which give maps.

TOKAT, a decayed provincial town of Turkey, in the vilayet of Sivas, and capital of the upper basin of the Iris (Yeschil Irmak), is a poorly-built place of about 10,000 inhabitants, in a hot, narrow valley, dominated by the ruins of a Byzantine castle, and surrounded by gardens watered by the Iris. It was once an important commercial station, and has still copper foundries. Six miles up the valley are the ruins of the Pontic COMANA (*q.v.*).

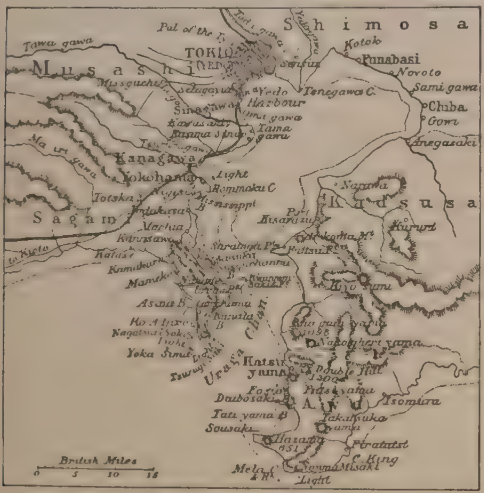
TOKAY, or TOKAJ, a small town in the county of Zemplén, in the northeast of Hungary, at the influx of the Bodrog into the Tisza, in 48° 7′ N. lat., 21° 4′ E. long. The slopes of the adjacent mountains of Hegyallya, which are of volcanic origin, produce excellent wine, several kinds of which are of perhaps the best, sweetest, and strongest quality in the world. Of these, however, none or hardly any come into the market, the wine usually sold under the name of Tokay not being a natural wine, and often not coming from the district at all. Tokay, along with about twenty-five neighboring villages, produces annually an average of 2,200,000 gallons. The vine culture has been greatly improved of late years by a company in Buda-pest. The timber trade, fishing, and export of fruits are also considerable. The population was 4479 in 1880.

---

[1] In Forcellini's *Lexicon* (ed. De Vit, 1875) we find "Todus genus parvissimæ avis tibias habens perexiguas." Ducange in his *Glossarium* quotes from Festus, an ancient grammarian, "Toda est avis quæ non habet ossa in tibiis; quare semper est in motu, unde Todius (al. Todinus) dicitur ille qui velociter todet et movetur ad modum todæ, et todere, moveri et tremere ad modum todæ." The evidence that such a substantive as *Todus* or *Toda* existed seems to rest on the adjectival derivative found in a fragment of a lost play (*Syrus*) by Plautus, cited by the same Festus. It stands "cum extritis [*extortis*] talis, cum todillis [*todinis*] crusculis;" but the passage is held by scholars to be corrupt. Among naturalists Gesner in 1555 gave currency (*Hist. Animalium*, iii. p. 719) to the word as a substantive, and it is found in Levin's *Manipulus Vocabulorum* of 1570 (ed. Wheatley, 1867, col. 225) as the equivalent of the English "Titmouse." Ducange allows the existence of the adjective *todinus*. Stephanus suggests that *todi* comes from τυτθοι, but his view is not accepted. The verb *todere* may perhaps be Englished to "toddle!"

[2] This habit and their green color has given them the French name of *Perroquet* or *Todier de terre*, by which they have been distinguished from other species wrongly assigned to the genus by some systematists; and, if we may believe certain French travellers, they must in former days have inhabited some of the Lesser Antilles; but that is hardly probable.

TOKIO, formerly called Yedo, the present capital of the empire of Japan, is situated in 35° 41′ N. lat. and 139° 46′ E. long., at the head of the bay of the same name, on the southeast coast of Hondo (mainland), the largest of the group of Japanese islands. It is connected with the seaport of Yokohama by a railway 18 miles in length. The bay of Tokio is shallow, and therefore not well suited for the navigation of large vessels. The wide river Sumida, also called Ôkawa ("great river") near its mouth, runs through the town. For administrative purposes Tokio proper is divided into fifteen *ku* (districts), of which thirteen lie to the west and two to the east of the Sumida. Each ku is presided over by an official appointed by the Government, called the *ku-chio* (chief of the ku), and an assembly (Ku-Kwai) for local administrative purposes is elected every four years by the inhabitants.



Environs of Tokio.

These ku and six *gun* (suburban districts) collectively form the Tokio-Fu, and are under the general superintendence of the *fu-chiji* (governor). Matters affecting the interests of the whole fu are discussed by an assembly (Fu-Kwai) composed of representatives from all the ku and gun. Order is maintained by a well-organized body of police (3648 men in 1885) under the command of a *keishisokan* (chief-commissioner), who, like the fu-chiji, is responsible to the central government. Since the establishment of this system crime has very materially decreased. There is also a fire brigade of 2000 men, which is connected with the police system, and renders effective service in checking the spread of the fires to which the town is peculiarly liable. Buildings of brick and stone have lately been erected in many parts of the town. The fifteen ku which form Tokio proper cover an area of 4.01 square *ri* [*c.* 6 sq. m.], and the six gun 27.94 square ri [166 sq. m.], the whole fu thus extending to about 32 square ri (about 190 square miles). The greater part of the town is flat, particularly near the Sumida, and is intersected by numerous moats and canals, which, with the bridges crossing them, form a distinctive feature. There are hills varying in height from 50 to 100 feet in the six districts of Hongo, Koishikawa, Ushigome, Yotsuya, Akasaka, Azabu, and in part of Shiba. The numerous residences of the old daimios were the chief characteristics of the town, especially in the Kôjimachi-ku. Many of these have been demolished and Government offices erected on their sites; some have given place to new streets and houses; others, having survived the downfall of the shogunate, still remain surrounded by large gardens, which are celebrated for their elaborate rock-work, artificial lakes, and magnificent trees. Nearly in the centre of the Kôjimachi-ku, on an eminence, surrounded by moats, stood the residence of the shoguns, which was burnt down in 1872. An imperial palace is now in course of construction on this site. Outer moats connected with those already mentioned enclose the whole Kôjimachi-ku and a greater portion of Kanda-ku; one of the moats terminates at the Sumida. The Nihonbashi, Kiobashi, and Kanda-ku, through which the Ô-dori (main street) passes, are the business quarters of the town. The Nihonbashi (bridge of Japan), in the ku of the same name, also in the Ô-dori, is the centre from which all distances are calculated. Nearly all the principal buildings of the city—such as the Gwaimushô (Foreign Office), the Naimushô (Home Office), the Ôkurashô (Ministry of Finance), the Monbushô (Ministry of Education), and other Government offices, etc.—are situated in those four ku. Among the parks, those of Shiba and Uyeno rank first in size and beauty, the latter containing a large sheet of water. In 1868, when the imperial army entered the city, a body of men called the shogitai, loyal to the cause of Tokugawa, here made a last stand, and during the fighting the magnificent temple of Tôyesau, on the hills of Uyeno, was burnt down. This part, as also the Mukojima (the embankment of the Sumida), and the Asukayama park, which is at some distance northwest of Uyeno, are celebrated for their sakura trees (species of cherry), which, when in full bloom, attract crowds of all classes. The famous temple of Kwannon (goddess of mercy) is in the Asakusa park, in which a continual fair is held, with the usual accompaniments of booths, shows, tea houses, etc. The districts of Fukagawa and Honjô lie on the east bank of the river, and are connected with the rest of the town by five wooden bridges of considerable length; they are intersected by numerous canals, and the streets there are regularly laid out. The means of communication are imperfect; the streets of Tokio are in general irregular, and many are so narrow that they are unsuitable for carriages. The *jinrikisha*, a kind of chaise drawn by one or in some cases by two or more men, supplies their place to a great extent. The introduction of tramways in some parts of the town has had the good effect of diminishing the number of second-rate carriages drawn by miserable horses.

There are no reliable data as to the population of Yedo during the shogunate (see below). Owing to the influx caused by the periodical visits of the daimios with their numerous attendants, it probably exceeded one million during the early part of the present century. At the abolition of the shogunate there was a marked decrease, but the returns of recent years (1,121,560 in 1881; 1,173,603 in 1883; 1,300,073 in 1885) indicate a rapid increase. Of the 1,519,781 who constituted the population in 1886, 1,211,357 are to be classed as belonging to the town proper, and 308,424 to the six suburban districts. The sanitary condition of the city leaves much to be desired, but extensive improvements are now being carried out. The general health, however, is good, and the enforcement of vaccination has virtually stamped out the scourge of small-pox. The deaths from cholera are occasionally very numerous, especially among the lower classes.

A well-organized system of education exists, under the supervision of the ministry of education. In 1885 there were in the Tokio-Fu 658 public and private elementary schools, with 1563 teachers,—the cost of maintaining public schools being 145,152 yen (Japanese dollars [or $143,700.48]). In the same year the boys and girls of school age numbered 172,653, of whom 77,001, attended schools recognized by the Government. Kindergartens on the European system have been introduced. There are also the *shihangakko* (normal schools), the *chugakko* (middle schools), and schools, both Government and private, for special branches. In the district of Hongo is the imperial university, sub-divided into the four branches of law, science, medicine, and literature. Many of the students attain a high degree of proficiency.

No mention is made of Tokio in Japanese history before the end of the 12th century. It appears to have assumed no importance till about 1457, when Ôta Dokwan, a general in the service of Uyesugi Sadamasa, governor of Kamakura, built a castle there. About thirty years later the town fell into the hands of Hôjô of Odawara, and subsequently on his overthrow by Hideyoshi and Iyeyasu, the castle was granted to the latter, who was the founder of the shogun house of Tokugawa. In 1590 Iyeyasu made his formal entry into the castle of Yedo, the extent of which he greatly enlarged. From this date the real importance of Yedo commenced. The family of the Tokugawas furnished the shoguns (or tycoons) of Japan for nearly three hundred years, and these resided during that period at Yedo. Under them the town was vastly extended, land was reclaimed from the bay, canals were constructed, and a water-supply introduced. The shoguns compelled the daimios (feudal lords) to reside at Yedo with their numerous retinues during a considerable portion of their lives, and thus the prosperity of the town rapidly increased. At the restoration of the supreme authority of the emperor in 1868 the shogunate was abolished, and the population of Yedo speedily decreased. A fresh vitality was again imparted by the transfer of the court from Kioto, and the town then received its present name Tokio (eastern capital). It has since been the seat of the imperial Government, and may be considered the centre of the political, commercial, and literary activity of Japan. It is the channel through which the stream of European civilization pours into the country, and all recent progress has there taken its rise. (R. S. L.)

TOLAND, JOHN (1670–1722), or Janus Junius, as his sponsors are said to have named him, usually described as a chief leader of the English deists, was born November 30, 1670 or 1671, in the north of Ireland, near Londonderry. He was the son, perhaps illegitimate, of Catholic parents, and was brought up in their faith. But in his fifteenth year he became a zealous Protestant, and in 1687 he passed from the school at Redcastle to Glasgow university, recommended by the magistrates of Redcastle "for his affection to the Protestant religion." Thus early in life he became "accustomed to examination and inquiry, and was taught not to captivate his understanding to any man or society." After three years at Glasgow he entered the university of Edinburgh, taking his M.A. degree there June 30, 1690. He then spent a short time in some Protestant families in England, and with their assistance went to Leyden university, to qualify him for entering the Dissenting ministry. He spent about two years in Leyden, studying ecclesiastical history especially under the famous scholar Frederick Spanheim. At the expiration of that time he took up his abode, January 7, 1694, at Oxford, having good introductions to Creech, Mill, and others. Here he made large use of the Bodleian Library, and soon acquired the reputation of being "a man of fine parts, of great learning, and of little religion," though there is no evidence to show that the last distinction was justly his due. His letters show that he then claimed to be a decided Christian, and that he was too orthodox to be classed with the Arians or the Socinians. At the same time the characteristic freedom and originality of his mind were displayed by his anticipation of subsequent doubts of the integrity of the book of Job, and the separation of the historical prologue and the speeches of Elihu from the original poem. While at Oxford he commenced the book which called him into notoriety, and became one of the standard "deistical writings"—his *Christianity not Mysterious.*[1] The book gave great offence, and several replies to it were immediately published. The author was prosecuted by the grand jury of Middlesex the year of its publication; and, when he attempted to settle in Dublin at the beginning of 1697, he was greeted with dangerous denunciations from the pulpits and elsewhere. He was soon prosecuted before the court of King's Bench, and on September 9th his book was condemned by the Irish parliament to be burned and its author to be arrested. He escaped the latter part of the sentence by flight to England. The title and the philosophical principles of Toland's book were singularly akin to those of Locke's famous work, *The Reasonableness of Christianity*, published the year before; and Locke's opponents seized the opportunity of fathering upon the philosopher the doctrines of his more heterodox and less guarded disciple. Thus Toland's work became the occasion of the celebrated controversy between Stillingfleet and Locke, in which Locke takes pains to show the difference between his position and Toland's. Toland's next work of importance was his *Life of Milton* (1698), in which, in connection with his exposure of the fictitious authorship of the *Eikon Basilike*, he found occasion to make reflections on "the numerous supposititious pieces under the name of Christ and His apostles and other great persons." This provoked the charge that he had called in question the genuineness of the New Testament writings, and he replied in his *Amyntor, or a Defence of Milton's Life* (1699), to which he added a remarkable list of what are now called apocryphal New Testament writings. In his remarks he really opened up the great question of the history of the canon, towards the examination of which Stephen Nye, Jeremiah Jones, and Nathanael Lardner made in reply to him the first valuable contributions. The next year his *Amyntor* and *Christianity not Mysterious* were under discussion in both Houses of Convocation, and the Upper House declined to proceed against the author. In 1701 Toland spent a few weeks at Hanover as secretary to the embassy of the earl of Macclesfield, and was received with favor by the electress Sophia in acknowledgment of his book *Anglia Libera*, a defence of the Hanoverian succession. On his return from the Continent he published a defence of himself, and of the bishops for not prosecuting him, *Vindicius Liberius* (1702), and several political pamphlets. The next year he visited Hanover and Berlin, and was again graciously received by the electress and her daughter Sophia Charlotte, queen of Prussia. On his return to England (1703) he published *Letters to Serena*, and afterwards acknowledged that the queen of Prussia was intended by the pseudonym. In these letters he anticipated some of the speculations of modern materialism. The next year appeared his *Account of Prussia and Hanover*, of which Carlyle has made use in his *Life of Frederick the Great.* From 1707 to 1710 he is again on the Continent,—at Berlin, Hanover, Düsseldorf, Vienna, Prague, and The Hague, with very varying fortunes, but generally of an adverse character. In 1709 he published *Adeisidæmon* and *Origines Judaicæ* (The Hague), in which, amongst other things, he maintained that the Jews were originally Egyptians, and that the true Mosaic institutions perished with Moses. This work provoked a number of replies from Continental theologians. In 1710 he returned to England, living chiefly in London and latterly at Putney, loving the country and his books, and subsisting precariously upon the earnings of his pen and the benevolence of his patrons. His literary projects were numerous (see the incomplete list in Mosheim); and the nobler traits of his warm Irish nature appear in his projected history of the ancient Celtic religion and his chivalrous advocacy of the naturalization of the Jews. The last of his theological works were *Nazarenus, or Jewish, Gentile, and Mahometan Christianity* (1718), and *Tetradymus* (1720), a collection of essays on various subjects, in the first of which, "Hodegus," he set the example subsequently followed by Reimarus and the rationalistic school in Germany, of interpreting the Old Testament miracles by the naturalistic method, maintaining, for instance, that the pillar of cloud and of fire of Exodus was a transported signal-fire. His last and most offensive book was his *Pantheisticon* (Cosmopoli, 1720). He died May 11, 1722, as he had lived, in great poverty, in the midst of his books, with his pen in his hand, and left behind him a characteristic Latin epitaph, in which he could justly claim to have been "veritatis propugnator, libertatis assertor."

---

[1] The first edition, London, 1696, was anonymous; the second, published the same year, bore on the title-page his name, and received a preface and some slight alterations; and the third appeared in 1702 with an appended *Apology for Mr. Toland.*

Toland is generally classed with the deists, but at the time when he wrote his first book, *Christianity not Mysterious*, he was decidedly opposed to deism, nor does Leland deal with that work as an exposition of deistical views. The design of the work was to show, by an appeal mainly to the tribunal of Scripture, that there are no facts or doctrines of the "gospel," or "the Scriptures," or "Christian revelation" which, when revealed, are not perfectly plain, intelligible, and reasonable, being neither contrary to reason nor incomprehensible to it. The work undoubtedly aimed a blow at some of the dogmas of later Christian times, but it claimed to be "a vindication of God's revealed will against the most unjust imputations" which occasioned "so many deists and atheists." Toland's line of argument is to show that the supposition of the doctrines of the gospel being repugnant to clear and distinct ideas and common notions leads into absurdities and inevitable skepticism; that the proof of the Divinity of Scripture is its self-evidencing power; that, though men are dependent on Divine revelation for the knowledge of the most important truths, the truths must themselves be plain and intelligible when revealed; that all the doctrines, precepts, and miracles of the New Testament are perfectly intelligible and plain; that, though reason is disordered in the case of many men, the disorder is not in the faculty itself but in the use made of it; that in the New Testament "mystery" never means anything inconceivable in itself, but things naturally intelligible enough, which are either so veiled by figurative words or rites, or so lodged in God's sole knowledge and decree, that they could not be discerned without special revelation; that no miracle of the gospel is contrary to reason, for they were all produced according to the laws of nature, though above its ordinary operations, which were therefore supernaturally assisted: that mysteries were first introduced into Christianity by the early admission into the church of Levitical ceremonies and heathen rites and mysteries, and especially by mixing up heathen philosophy with the simple religion of Christ. The work was intended to be the first of three discourses, in the second of which he was to attempt a particular and rational explanation of the reputed mysteries of the gospel, and in the third a demonstration of the verity of Divine revelation against atheists and all enemies of revealed religion. But, like so many other of his numerous projects, this failed of execution. After his *Christianity not Mysterious* and his *Amyntor*, Toland's *Nazarenus* was of chief importance, as calling attention to the right of the Ebionites to a place in the early church, though it altogether failed to establish his main argument or to put the question in the true light. His *Pantheisticon, sive Formula celebrandæ Sodalitatis Socraticæ*, of which he printed a few copies for private circulation only, gave great offence as a sort of liturgic service made up of passages from heathen authors, in imitation of the Church of England liturgy. The title also was in those days alarming, and still more so the mystery which the author threw round the question how far such societies of pantheists actually existed. Poor Toland had been outlawed by the churches of his day, and took a most imprudent delight in alarming and mystifying his persecutors. This and all his later works must be read from the point of view first suggested by Herder; "Who can refuse to see in Toland the man of wide reading and of clear intellect, and the earnest inquirer, although, as embittered by persecutions, with every fresh book he dipped his pen in a more biting acid?"

See Mosheim's *Vindiciæ Antiquæ Christianorum Disciplinæ*, 1st ed., 1720, 2d ed., 1722 (the life of Toland prefixed to the 2d edition of this essay gives still the best and most learned account we have of his life and writings); "Memoirs of the Life and Writings of Mr. John Toland," by Des Maizeaux, prefixed to *The Miscellaneous Works of Mr. John Toland*, in 2 vols., London, 1747; Leland's *View of the Principal Deistical Writers*; Herder's *Adrastea*; Lechler's *Geschichte des englischen Deismus*; Isaac Disraeli's *Calamities of Authors*; *Theological Review*, November, 1864; Hunt's article in *Contemporary Review*, vol. viii., and his *Religious Thought in England*; Leslie Stephen's *History of English Thought in Eighteenth Century*; Cairns's *Cunningham Lectures for* 1880. On Toland's relation to the subsequent Tübingen school, as presented in his *Nazarenus*, see *Theological Review*, Oct., 1877; and on his relation to materialism, F. A. Lange's *Geschichte des Materialismus*. (J. F. S.)

TOLEDO, a province of Spain, in New Castile, is bounded on the N. by Avila and Madrid, on the E. by Cuenca, on the S. by Ciudad Real, and on the W. by Cáceres, and has an area of 5620 square miles. The surface is throughout lofty, and in a great part of its extent mountainous. Towards the centre, indeed, there are extensive plains or tablelands, but the whole of the south and east is occupied by the Montes de Toledo, which separate the waters of the Tagus on the north from those of the Guadiana on the south. These mountains are of no great height; and they were once densely covered with forests, which have now been almost entirely cut down, although there are still woods and groves of considerable extent on their lower slopes. Branches of this chain enclose the province on the east and west, and part of the range that stretches north of the Tagus approaches its northwestern frontier. Toledo is well watered by the Tagus and its affluents,—the Tajuna, Jarama, Guadarrama, Alberche, and Tietar on the north, and the Algodor, Torcon, Pusa, Sangrera, and Cedron on the south. The Guadiana forms for a short distance the southwestern frontier, and its tributary the Giguela waters the eastern part of the province. The country is rich in minerals, as yet almost entirely unworked, containing veins of gold, silver, lead, iron, quicksilver, copper, and tin. Coal, alum, cinnabar, etc., are also found. The soil produces corn, pulse, potatoes, oil, wine, flax, oranges, lemons, chestnuts, and melons in fair abundance, but the trade in agricultural products is almost confined to the province itself. The number of sheep and goats is few, of horses and mules still less; while the only oxen are those used in agriculture. Bees and silkworms are kept in considerable number. Manufactures once flourished, but are now in a very low state,—silk and woollen cloth, earthenware, soap, oil, chocolates, wine, rough spirit (*aguardiente*), guitar strings, and arms being almost the only articles made. The province is traversed by three lines of railway,—that of Madrid-Seville-Cadiz in the east, Madrid-Toledo-Ciudad Real through the centre, and Madrid-Cáceres-Lisbon in the north. There are 12 partidos judiciales and 206 ayuntamientos; and three senators with eight deputies are returned to the cortes. The total population in 1885 was 332,000; the only towns with a population exceeding 10,000 are Toledo (20,251) and Talavera de la Reina (11,986). Some of the most brilliant fighting of the Peninsular War took place in Toledo and the neighboring province of Cáceres, the battle of Talavera de la Reina being fought on the 27th and 28th of July, 1809.

TOLEDO, the capital of the above province, and once of the whole of Spain, stands upon a circle of seven hills, 2400 feet above the sea, and washed on three sides by the Tagus. It is 37 miles west-southwest of Madrid. The river is spanned by two fine stone bridges,—the Alcántara, a Moorish bridge of a single arch, giving entrance to the city from the east, and the other, that of San Martin, from the west, while between them the river makes a sweep southwards. The place is enclosed on the land side by two walls, still in fairly perfect condition,—the inner one being built by King Wamba in the 7th century, the outer by Alfonso VI. in 1109. The gates are numerous and well preserved, the most noteworthy being the famous Puerta del Sol, the Puerta Visagra, and the Cambron. Some Roman remains (a circus, etc.) lie without the walls, on the plain to the northwest. The appearance of Toledo from a distance is imposing in the extreme, from its noble situation and the terraced lines of its buildings; but upon a nearer approach it reveals itself as dull and decayed enough, with little or no traffic in the streets, and a strange silence brooding over all its ways. The houses are large, massive, and gloomy, generally Moorish in style, of the 12th, 13th, and 14th centuries, with a great central *patio* (courtyard), and yielding abundant traces of Arabic decoration. The principal public square is the Zocodover. It forms the favorite promenade, and from it the one fairly wide street of the city leads to the cathedral. The latter is the glory of Toledo, and one of the finest monuments of art in Spain. Built upon the site of an ancient mosque, and commenced in 1227 it was completed in 1492; and, though sacked over and over again,—finally by the French under La Houssaye in 1808,—it is still, with the exception, perhaps, of the cathedral of Seville, the richest and most magnificent foundation in the Peninsula. The exterior is unfortunately hidden to a great extent by mean surrounding buildings, but the fine western façade, with its two towers, one rising 325 feet, is effective. The interior is somewhat dwarfed in appearance by the immense width. It is 404 feet long by 204 feet broad, and is divided by 84 pillars into five naves, with central lantern and choir, and a complete series of side chapels. Most of these latter are late additions, of the 15th and 16th centuries, and are very magnificent in detail. The 16th-century stained-glass windows, chiefly of Flemish work, are superb; and the treasury, reliquaries, and library, notwithstanding their repeated despoilings, are not unworthy of the see which styles itself the "first of all the Spains." In the Muzarabic chapel the ritual known by that name is still performed daily. Within the precincts of the cathedral are interred the archbishops and cardinals Tenorio, Fonseca, Mendoza, Ximenez, the great constable Alvaro de Luna, and a long array of kings and heroes. The archbishop is primate of Spain, and has for suffragans Coria, Cuenca, Siguenza, and Palencia. Besides the cathedral Toledo still possesses a great number of fine churches and other religious buildings, together with numerous Moorish and Jewish monuments. The most important church is the 15th-century florid Gothic San Juan de los Reyes, built by Ferdinand and Isabella. The best Moorish work is to be found in the old Jewish synagogues of Santa Maria la Blanca and El Tránsito, in the mosques of Cristo de la Luz and Las Tornerias, in some private houses, and in the later churches of San Roman, Santo Tomé, Santiago, and Santa Leocadia. The patio and staircase of the hospital of Santa Cruz present some of the finest Renaissance work extant. Seen from afar, the Alcazar, or royal palace, is one of the most conspicuous features of the city. It stands upon a commanding position overlooking the Tagus, and was originally built by King Wamba, but has been repeatedly altered and pulled about. It was almost entirely rebuilt by Charles V. and Philip II., under the architects Covarrubias and Herrera, and has lately been converted into a huge military academy. The city is provided with numerous elementary schools, a public library, museum, town-hall, and several large hospitals. The well-known manufactory of swords is about a mile to the north-west, beyond the Cambron gate. It is in excellent order, and produces blades as perfect as ever, but is no longer of great importance, employing only about 120 hands.

Toledo existed in the time of the Romans, who conquered it in 193 B.C. They strengthened the fortifications, and built an aqueduct to supply the place with water. By the Goths, who captured the city in 467 A.D., these works were kept up and improved; and, under the Moorish domination, from 714 to 1085, Toledo was second only to Cordova in rank and importance, with a population of 200,000 souls. Alfonso VI. of Castile and Leon recovered the stronghold in 1085; and under him and his successors it continued to flourish until the permanent establishment of the court at Madrid gave a deathblow to its prosperity. The population now is no more than 20,000.

TOLEDO, a city of the United States, the county seat of Lucas county, Ohio, is situated in 41° 40′ N. lat. and 83° 33′ W. long., chiefly upon a peninsula between the Maumee on the south and the Ottawa upon the north, just above their points of discharge into Maumee Bay, and 5 miles from Lake Erie. A small part of it, formerly known as Maumee City, lies south of the Maumee. Toledo includes an area of 21.5 square miles within its corporate limits. The bay and river form an excellent harbor and roadstead. The harbor is easily made and is well sheltered, and the bottom affords good holding ground. Besides being open to the navigation of the Great Lakes, Toledo is the terminus of the Miami and Erie Canal, connecting it with Cincinnati (184 miles distant). Seventeen railroad lines enter it, making it one of the principal railroad centres of the country. The site of Toledo and the surrounding country are very level, and only slightly elevated above Lake Erie. The soil is very productive, and is highly cultivated, being largely devoted to market gardening. There are three public parks, having a total area of 41 acres. The city is well sewered. Water is obtained by pumping. The city, which is divided into eight wards, had in 1880 a population of 50,137. The number is probably now (1887) not far from 65,000. In 1840, 1850, 1860, and 1870 respectively the population was returned at 1224, 3829, 13,768, and 31,584.

Besides its large commercial interests, as one of the principal ports upon the Great Lakes, and its importance as one of the leading railroad centres of the country, Toledo holds high rank as a manufacturing city. The capital invested in this class of industries in 1880 exceeded $5,500,000, and the products were valued at double this sum. They employed nearly 7000 persons, and paid in wages over two and a quarter millions of dollars. These industries are very varied in character, but consist largely in lumber manufactures, brewing, and iron and steel manufactures.

The first settlement within what are now the corporate limits of Toledo was made, shortly after the war of 1812, upon the south bank of the Maumee. North of the river no settlements were attempted until 1832, when the villages of Port Lawrence and Vistula were commenced in what is now the heart of the city. In the following year they were united under the present name. The city was incorporated in 1837. In 1852 it was made the county seat, and in 1874 its corporate limits were considerably enlarged.

TOLL is a sum of money paid for the use and enjoyment of a privilege. In England it is now always or almost always a sum of money; but formerly tolls in kind were not unknown. An instance is afforded by the Act of 36 Geo. III. c. 85, substituting a money payment for tolls of corn in kind taken by millers, with an exception in favor of tolls taken by custom in soke mills. Such customary tolls, if any such now exist, are apparently the only examples remaining of tolls in kind. The Weights and Measures Act, 1878, enacts that all tolls are to be charged and collected according to imperial weights and measures.

The word toll, in its earliest use, appears to have signified a franchise enjoyed by lords of manors, and is defined by Glanvill as the liberty of buying and selling in one's own land: "tol, quod nos vocamus theloneum, scilicet libertatem emendi et vendendi in terra sua." The word then became used to denote duties payable to the crown, especially on wool, generally with an inseparable epithet indicative of unpopularity. It thus took the form of "maletote" or "malum tolnetum,"[1] against which many early statutes were directed, from the Magna Carta of John till the final abandonment of the duty by Edward III. In modern English law toll is either an incident of a FRANCHISE (*q.v.*), as of a market or fair, or is independent of franchise. In the latter case it is claimed by prescription, as toll traverse or toll thorough, or is created by Act of Parliament, as in the case of turnpikes, railways, harbors, navigable rivers, and canals. Toll traverse is paid for passing over a private way, bridge, or ferry. No consideration need be proved. Toll thorough is paid for the use of a highway. In this case, if charged by a private person, some consideration, such as repair of the highway, must be shown, as such a toll is against common right. In one case, that of the Cornish custom of tin-bounding, the right to tin tolls may depend upon custom. At common law a toll must be reasonable. The same principle appears in various Acts of Parliament. The Statute of Westminster the First, 3 Edw. I. c. 31, inflicts a penalty for taking excessive toll. The Railway Clauses Consolidation Act, 1845, and most special Acts of railway companies provide, by what are known as "the Shaftesbury clauses," for the equality of tolls, that is, that all persons and classes of goods shall under like circumstances be treated alike as to charges. A right of distress is incident to the right to impose tolls, but the distress cannot be sold unless an Act of Parliament expressly authorizes the sale. Tolls are rateable for the relief of the poor where they are appurtenant to land, but not where they are extrinsic profits not arising from the possession of land. Exemption from tolls may be claimed by the prerogative, by grant or prescription, or by Act of Parliament. The king pays no toll, and may grant to another exemption from toll. The exemptions by Act of Parliament mainly affect persons in the public service, clergy on their parochial duty, and persons going to or returning from their usual place of religious worship. Most of the exceptions from turnpike tolls will be found in 3 Geo. IV. c. 126. Turnpike tolls, bridge money, and causeway mail were abolished in Scotland by the Roads and Bridges Act, 1878, as from the 1st June, 1883. In England there has been no such general abolition, but the abolition of tolls has been facilitated by several recent Turnpike Acts, and their entire disappearance is only a question of time.

---

[1] The same term was known in mediæval Italy. Dante, in *Inferno*, xi. 36, alludes to "tollette dannose."

In the United States tolls are a subject for State legislation, except in a few instances in which Acts of Congress have dealt with tolls in rivers and harbors (see Revised Statutes, tit. lxiii).

The question of tolls was at one time an important one in international law. Tolls were exacted on certain straits and tidal rivers by virtue of the sovereignty of a particular state. Such tolls have mostly ceased or been redeemed. Notable instances were the Scheldt tolls and the Sound dues levied by Denmark. See NAVIGATION LAWS.

TOLUCA, or TOLOCCAN, a city of Mexico, the capital of the state of Mexico, on the Mexican National Railway, 45 miles southwest from the federal capital. It lies on the west side of the Anahuac tableland, at the foot of Mount San Miguel de Tutucuitlalpillo, at an elevation of 8653 feet above the sea, being the highest town in the republic next to the mining station of Ameca-meca (which is 8800 feet). Toluca had in 1886 a population of about 12,000, and is usually described as a well-built flourishing town, with fine buildings and clean well-drained streets. But T. M. Brocklehurst, who visited it in 1880, gives an unfavorable impression of the place, which presented nothing attractive beyond the Portales, a fine arcade running round a large block of central buildings, with a number of good shops under the arches (*Mexico To-day*, p. 222). There is also a good theatre, and in the Plaza de los Martires a well-executed white marble monument to the patriot Miguel Hidalgo y Costilla. But the Carmen, Vera Cruz, and one or two other churches are dirty and tawdry, without presenting any striking architectural features. The city is traversed by a foul stream flowing at the bottom of a barranca or deep ravine, along whose banks are herded numerous swine in a half-wild state, which supply the hams and sausages for which the place is noted. Here also soap and wax candles are manufactured and supplied to the surrounding districts. In the southwest the Nevado de Toluca, an extinct snow-clad volcano with a flooded crater, rises to a height of 15,156 feet above sea level.

Although Toluca appears to have been one of the earliest Toltec settlements in Anahuac, its foundation dating probably from the 6th century, it has preserved no remains of its ancient grandeur, nor have any monuments been discovered in the district in any way comparable to those of Cholula, Tula, Teotihuacan, and other ancient centres of Toltec culture. According to M. Charnay, Toluca formed one of the chief starting points of the great migrations which, after the overthrow of the Toltec empire by the Chichimec irruption in the 11th century, moved in two parallel streams southwards, converging at Copan and spreading their arts and industries over Chiapas, Yucatan, and Guatemala (*Ancient Cities of the New World*, 1887, p. 125).

TOMATO. See HORTICULTURE, vol. xii. p. 301.

TOMPA, MIHÁLY (= MICHAEL) (1817–1868), one of the best and tenderest Hungarian lyric poets, was born in 1817 at Rima-Szombat, in the county of Gömör, of very humble parentage, his father being village bootmaker. He studied law and theology in Sáros-Patak, and subsequently at Budapest; but, feeling little inclination for the first-mentioned career, after many vicissitudes he, at the age of thirty, accepted the post of Protestant minister in Beje, a small village in his native county, whence, in two years, he removed to Kelemér, and four years later to Hanva, in the county of Borsod, where he remained till his death in 1868.

At the age of four-and-twenty Tompa published his first poems in the *Athenæum*, which soon procured for him a high reputation. His first volume, *Népregék és Népmondák* ("Folk-Legends and Folk-Tales"), in 1846, met with great success, and the same may be said of the first volume of his "Poems" in 1847. In 1848 he took part in the war of independence, acting as field chaplain to the volunteers of his county and seeing several battles; but the unfortunate close of that heroic struggle silenced his poetic vein for a considerable time, and when in 1852 and 1853 he gave vent to his patriotic grief in some masterly allegories on the state of oppressed Hungary, he was twice arrested by the Austrian authorities. After being released he published his *Virágregék* ("Legends of Flowers"), a collection of poems of the highest order, showing great imagination and love of nature, and displaying the loftiest humanity and great meditative power. Soon after this he became oppressed with melancholy and abandoned this branch of poetry. Indeed from this time he produced comparatively little. He published three volumes of sermons, "which," says his biographer, Charles Szász, Protestant bishop of Budapest, "are among the best in Hungarian literature, and will favorably compare with those of Robertson, Monod, or Parker." His collected poetical works, in six volumes, were published at Budapest in 1870, and again, in four volumes, in 1885.

TOMSK, a government of Western Siberia, extending from the Chinese frontier to 60° N. lat., is bounded by Tobolsk on the N.W., by Yeniseisk on the N.E., by the Chinese province of Khobdo on the S.E., and by Semipalatinsk on the S.W. Its area, 329,040 square miles, is fully one and a half times that of France. The surface is most varied, including in the southeast the high alpine tracts of the Altai Mountains, with an elevated steppe which skirts these, and in the northwest and west the lowlands of the Irtish and the marshy tracts of the Ob.

The Altai Mountains, which cover within the limits of the Russian empire an area of 53,000 square miles, or three times that of the whole of Switzerland, although visited by many geologists, still remain very imperfectly known, even as regards their orography. The country has been mapped only along the rivers and the course of a few footpaths, and great confusion still prevails with reference to the directions of the different chains of the Altai and their mutual relations (compare SIBERIA). The best descriptions, however (including the most recent by M. Potanin),[1] indicate in that part of Asia the very same leading orographical features that are seen in the Tian-Shan Mountains farther south, and in the West Sayan range farther north. A plateau with an average altitude of more than 4000 feet, watered by the tributaries of the upper Yenisei, all flowing in open valleys 3000 to 4000 feet above the sea, is known to rise in that part of northwestern Mongolia which is drained by the upper Yenisei and Selenga. The surface of this plateau is diversified by ridges, and by depressions like that of the Ubsa-nor—a relic of what was formerly a much larger lake. A lofty mountain chain, which has its southeast foot on the plateau and its northwest foot in the valley of the Us, fringes the plateau, and has all the characters of a border-ridge. The present writer has proposed to call this Erghik-shan. It runs from northeast to southwest along the Russo-Chinese frontier, and is pierced by a deep gorge through which flows the Yenisei. A belt, some 200 miles in width, of alpine tracts, made up of three or four chains parallel to the border ridge, fringes the outer border of the plateau, and fills up the Minusinsk region. The structure of the hilly tracts (watered by the Kemtchik) between the Yenisei and the Altai remains quite unknown, no scientific man or topographer having ever visited it. But the very same orographical features as those already described reappear in the Altai region. There is now no doubt that the backbone of the Altai is a huge and lofty border-ridge, the Sailughem, which includes the small alpine plateaus of Ukek, the upper Tchuya, and Juvlu-kul, and runs from southwest to northeast, being a continuation of the border-ridge of the West Sayan. Its flat dome-shaped summits rise to about 10,000 feet, and the small alpine plateaus just named range from 7800 to 8200 feet in elevation. It has a very steep slope towards the northwest, *i.e.*, towards the broad valleys of the upper Bukhtarma and Tchuya, and a very gentle slope towards the southeast, and its southeastern hillfoots are on the level of the plateau of Khobdo (from 4500 to 5000 feet). A broad alpine region spreads to the northwest of the border-ridge, but in the imperfect state of our knowledge it is difficult to discriminate the real directions of its chains. Nevertheless, another lofty chain, containing the snowclad Alps of the Katuñ (Katunskiye Byełki) and those of the Tchuya, and running also from southwest to northeast, parallel to the Sailughem border-ridge, can be distinguished in the labyrinth of confusedly scattered mountains seen on our present maps. It is one of the most picturesque chains of the region, and contains the Byelukha peak, estimated at 11,000 feet, and the Alas-tu, of nearly the same height. It is pierced, however, by so many rivers, which rise on the northwest edge of the plateau, and find their way to the lowlands by a series of gorges, that its continuity could be easily overlooked. Farther to the northeast it joins, in the opinion of the present writer, the high chain on the left bank of the Kemtchik, which is continued by the picturesque Alps on the northern bank of the Us. A third system of mountain chains, also parallel to the above, can be distinguished in the succession of the Terektinsk Mountains, those which are pierced by the Tchulyshman and those which follow the right bank of the Abakan; while traces of a fourth plication of the rocks may be discovered in the Tigeritsk Mountains, those pierced by the Biya below Lake Teletskoye, and the Kuznetskiy Ałatau, on the left bank of the Abakan. A number of smaller, much lower, and shorter chains faintly appear as outer walls of this extensive alpine region. As for the Great Altai, or Altain-Nauru, our knowledge of which has been greatly increased by the recent explorations of M. Potanin,[1] it may be regarded as a southwestern border-ridge of the Khobdo plateau, with its steep slope facing towards the wide Dzungarian depression, or rather to the broad trench of the Ulungur. Its direction is nearly at right angles to the above, running from northwest to southeast, like the Tarbagatai Mountains (see TURKESTAN), and it is continued farther to the southeast by the Irdyn-ula and Artsa bogdo Mountains, which separate the eastern Gobi from the Tarim depression. It is most probable that upheavals, having the same northwestern direction (which, according to M. Mushketoff, are in Central Asia more recent than the northeastern ones), have to a certain extent modified the old northeastern chains of the Altai, and complicated the chains of its alpine region. If so, the structure of the Altai would be very similar to that of the Turkestan mountains. A chain having a northwestern direction—the Salair Mountains—shoots off from the main ranges of the Altai, between the Tom and the Tchumysh; it is about 170 miles in length, with a width of nearly 60 miles, and contains the best silver mines of the region, as also several gold-washings. Its upheaval belongs to a more recent epoch than that of the Sailughem ridge, and (like the mountains of Turkestan, having a northwest direction) it is due to dioritic rocks. In the Kuznetsk depression it is covered with deposits of the Lower and Upper Carboniferous, containing beds of coal. The Kuznetskiy Ałatau, in which Humboldt saw one of his meridional upheavals, consists of a series of ridges running southwest to northeast, with further continuations within South Yeniseisk.[2]

---

[1] *Jivopisnaya Rossiya*, vol. xi.; *Sketches of N. W. Mongolia*, vols. i. and iii.; Addenda to Ritter's *Asia*.

The alpine region of the Altai is most picturesque; most of its chains, rising over 8000 and 9000 feet, are snowclad, and a great glacier descends from the hollows under the Byelukha peak; several other less known glaciers occur in the different "byełkis" (snowclad chains). A thick forest vegetation clothes the mountain slopes, while beautiful valleys, often of great length, such as that of the Bukhtarma (180 miles) or that of the Uimon and Koksu, offer on their fertile and well-sheltered floors most favorable conditions for agriculture. Several lakes are met with, some, like the Juvlu-kul and Kendykty-kul on the small alpine plateaus, at heights where only the dwarf birch grows and the polar marmot takes up its abode, while two others, Lakes Kołyvanskoye and Teletskoye, respectively 1170 and 1600 feet above the sea, from their position amidst steep and picturesque mountains, recall those of Geneva and Lucerne.

The Altai flora is very rich. Although the European flora (including the beech) which clothed the Altai at a recent period has disappeared, and the Siberian flora invades its hillfoots from the northwest, while the steppe flora is advancing from the south, still in a zone ranging from 1000 to 6000 feet above the sea the botanist has to admire a flora rich in bright flowers, tall grasses, and shrubs, several of which are now common ornamental plants in European gardens; and the zoologist discovers in the Altai the meeting-place of the northern fauna (including the reindeer) with that of the high Central-Asian plateau (including the tiger and the two-humped camel of Bactriana).

A strip of elevated plains or grassy steppes, also about 200 miles in breadth, girdles the alpine region upon the northwest. Its outer border can be roughly indicated by a line running northeast from Lake Gorkoye to Tomsk. They have an average altitude of from 700 to 1000 feet above the sea, and are covered with a luxuriant grass vegetation; the conditions for agriculture are excellent, and Russian villages are rapidly springing up. The southwest portion is known as the Kumandinsk steppe. An innumerable succession of small lakes—rivers in the process of formation—cover this steppe, where we have a system of parallel undulations, resulting in tributaries of the Ob, all flowing northeastward with remarkable regularity.

Beyond the high plains, that is, all over northwestern Tomsk, are the lowlands, which may be subdivided into two portions,—The Baraba steppe in the southwest (see TOBOLSK), and the marshy region of the Ob (the Vasyugan and Narym regions). The latter is one boundless marsh, a few settlements of native hunters occurring only along the rivers. The interior is for the most part inaccessible alike to boats and to human feet. Low hills, or rather swellings, intersect it, but even the highest points, barely 200 or 300 feet above the sea, are covered with marshy forests. The forests themselves grow on marshy ground; but where the trees disappear one sees for hundreds of miles nothing but green flowery carpets, which, when trodden on, treacherously yield under the unwary traveller. Similar in character must have been the marshes in which the Siberian mammoths and rhinoceroses of the Quaternary epoch found their graves. Only the light and broad-hoofed reindeer, but not the elk, can cross them. This inhospitable region is inhabited only by Ostiaks, who have been driven into it by stress of circumstances, and support themselves partly by fishing and partly by hunting.

[2] Kropotkine, "Orographical Sketch of the Districts of Minusinsk and Krasnoyarsk," in *Mem. Russ. Geogr. Soc.*, vol. v., 187[illegible].

The Sailughem ridge, and the high Khobdo plateau as well, consists of granites, syenites, porphyries covered only with the oldest metamorphic slates belonging to the Archaic formation (Huronian and Laurentian). The structure of the outer chains of the Altai is more complicated. Their backbone is also composed of granites, porphyries, and porphyrites covered with metamorphic slates which are intersected by layers of crystalline limestones, breccias, and veins of jade.[1] Diorites, diabases, augitic porphyries, and hypersthenites also appear, but they are of a more recent origin. Silurian clay-slates are widely spread in the southern Altai. Devonian slates and limestones are also developed in the southern Altai, and the metalliferous deposits of Zmeinogorsk, Petrovsk, Riddersk, etc., belong to that age. Carboniferous dolomitic limestones and slates are widely spread both in the southern and northern Altai. After the Carboniferous epoch the southern Altai was not again submerged, while the northern Altai was covered by the Jurassic sea, and has thick Jurassic deposits containing a copious fossil flora and rich beds of coal. Basaltic eruptions, dating from the Jurassic period, have been found in the Salair Mountains. Thick diluvial deposits cover the whole area, and in many valleys are traces of immense former glaciers; in fact, the whole of the Sailughem ridge must at one time have been clothed with an ice-cap.[2]

The southern Altai is rich in silver, copper, lead, and zinc; while in the Ałatau are concealed its chief auriferous alluvial (or diluvial) deposits, iron-ores, and coal-seams. The mineral wealth of the Altai is really immense, but only a very few of the mines already known are worked. In 1881 4030 ℔ of gold, 14,820 ℔ of silver, 13,100 cwts. of lead, 6720 cwts. of copper, 240,000 cwts. of coal, 330,000 cwts. of salt, and 30,000 cwts. of bitter salt were obtained. In the same year only 3000 cwts. of iron were manufactured, and that metal is still imported from the Urals. The jade, beautiful porphyries, and the like of the district, which are cut into works of art at the crown works of Kołyvañ, are well known through the urns and vases shown at the St. Petersburg Hermitage. The mineral waters of the Altai are of high quality.

Tomsk is watered mainly by the Ob and its tributaries, only its southeast corner draining into the Abakan, a tributary of the Yenisei. The Ob, formed by the union of the Biya and Katuñ, has within the government a course of more than 800 miles, and is navigated as far as Barnauł and Biysk. Its tributaries, the Tom (450 miles), the Vasyugan (530 miles), the Ket (230 miles), and the Tym (200 miles), are all navigable. The Tchułym and the Tchumysh are also great rivers. Of tributaries of the Irtish, the Bukhtarma, the Om, the Uba, and the Tara are worthy of notice. As many as 1500 lakes have been counted on the maps, but this number is exceeded by the reality. Some of them are alpine; others dot the steppes or the marshy tracts. Lake Tchany, notwithstanding its rapid desiccation, still covers 1265 square miles. Many brackish lakes, Kułundinsk, Kutchuk, etc., attain a great size, and some small salt lakes yield about 100,000 cwts. of salt.

The climate is very severe, and has, moreover, the disadvantage of being very wet in the northwest. The average yearly temperatures at Tomsk, Kainsk, and Barnauł are 30.2°, 31°, and 32.7° (January, 4°, — 6.2°, and 3.7°; July, 65.5°, 68.5°, and 62.2°). The Altai steppes, enjoying a much drier climate than the lowlands, are covered with a beautiful vegetation, and in the sheltered valleys corn is grown to heights of 3400 and 4250 feet.

The population, which is rapidly increasing, in 1882 reached 1,134,750. The Russians are in a large majority, the indigenous inhabitants numbering in 1879 only 63,600, or 6.6 per cent. of the aggregate population. They include 23,600 Altaian Tartars, 5730 Teleutes, 17,020 Mountain Kalmucks (see TARTARS), 10,000 Tomsk Tartars, 2920 Samoyedes, and 4210 Ostiaks. The prevailing religion is Greek-Orthodox, but there are also some 50,000 Nonconformists, 7320 Catholics, 2600 Jews, 10,700 Mohammedans, and about 28,000 pagans.

Agriculture is the prevailing occupation. It is most productive on the elevated plains of Tomsk, Mariinsk, Barnauł, Kuznetsk, and Biysk. Cattle-breeding is much developed, especially in the Kułundinsk steppe; and bee-keeping is an important source of wealth. Fishing and hunting are extensively carried on in the forest region. Mining occupies several thousands of men in the Altai. Manufactures are insignificant, the aggregate production —chiefly from distilleries and tanneries—hardly amounting to £250,000 [$1,215,000]. Trade is actively carried on at Tomsk and Barnauł, which are two great centres for the export and import trade of Siberia with Russia. The Biysk merchants carry on exchange trade with Mongolia and China. There are eight gymnasia (696 boys and 569 girls in 1883) and 225 primary schools (5680 boys, 1730 girls). The government is divided into six districts, the chief towns of which (with populations in 1884) are Tomsk (31,380), Barnauł (17,180), Biysk (18,960), Kainsk (4050), Kuznetsk (7310), and Mariinsk (13,090). Narym (1600) also has municipal institutions; it is the centre for the administration of the wide Narym region. Of the above towns only Tomsk and Barnauł have the aspect of European towns. Barnauł, capital of the mining district of the Altai, which belongs to the "Cabinet of the Emperor," is a wealthy city, with a mining school and laboratory, a botanic garden, a museum of mining and natural history, and a meteorological observatory. Kołyvañ, with a stone-cutting manufactory, has 12,250 inhabitants. Several mining villages are more important than the district towns: Zyryanovsk (silver-mine; 4500 inhabitants), Riddersk, Zmeinogorsk (6160), Suzunsk (5400), and Salairsk (3500).[3] (P. A. K.)

TOMSK, capital of the above government, is situated on the Tom at its confluence with the Ushaika, 27 miles above its junction with the Ob, and 2377 miles from Moscow. It is one of the chief cities of Siberia, second only to Irkutsk in population and trade importance. The great Siberian highway from Tyumeñ to Irkutsk passes through Tomsk, and it is the terminus of the navigation by steamer from the Urals to Siberia. It has, moreover, communication by steamer with Barnauł and Biysk in the Altai. The position of Tomsk determines its character, which is not that of an administrative centre, like so many Russian cities, but that of an entrepôt of wares, with many storehouses and wholesale shops. Before 1824 it was a mere village; but after the discovery of gold in the district it grew rapidly; and, although the immense wealth that accumulated suddenly in the hands of a few proprietors of gold diggings was as rapidly squandered, it continued to maintain its importance, owing to the navigation on the Irtish and the Ob, which meanwhile had grown up. It is built on two terraces on the high right bank of the Tom, and is divided into two parts by the Ushaika. The streets are rather narrow and steep; many houses of the richer merchants are of stone, but rather heavy in appearance, and altogether the aspect of the streets is not attractive. The best building is that of the future university, which is a spacious and elegant structure, with ample accommodation for library, museums, and clinical hospitals. The Government has not as yet given permission to inaugurate the building. A large cathedral, begun some five-and-twenty years ago by proprietors of gold diggings, collapsed after considerable progress had been made. The industries are almost entirely confined to tanning and the manufacture of carriages. The trade is of great importance, Tomsk being not only a centre for traffic in local produce, in which sledges (50,000 every year) and cars are prominent items, but also for the trade of Siberia with Russia. The population in 1884 was 31,380.

TONGA. See FRIENDLY ISLANDS.

TONG-KING, TUNG-KING, TONQUIN, or, as it is called by the Annamese, DONG-KING, consists of that portion of Annam between 18° N. lat. and the frontiers of the Chinese provinces of Kwang-se and Yun-nan, with an area of 60,000 square miles. On the W. it is bounded by the Tran-ninh range, which forms the limit of the Lao states, and on the E. by the sea. In shape it resembles, roughly speaking, an isosceles triangle, having its apex at its juncture with Annam and its base along the Chinese boundary. The name Tong-king, "the eastern capital," was originally applied to Hanoi, but was eventually adopted as that of the whole country. It is the same word as TOKIO (*q.v.*).

See vol. xxi. Pl. IX.

Geographically Tong-king is divided into three well-defined areas. First, there is the delta of the Song-koi ("Red river") and its affluents, which, beginning at Sontay, widens out into the low lands which constitute the most fertile district in Tong-king, and within which are situated the principal cities of the country. Here is grown the rice which constitutes 39 per cent. of the total exports from Tong-king, and which is reckoned in the Hong-Kong market to be equal in quality to the rice from Siam and superior to that from Cochin-China. During the rainy season this part of the country, with the exception of the embankments, is under water, but notwithstanding this the climate is fairly healthy, and the prevalence of fever and dysentery is not so great as might be expected. From the delta northward and westward rise plateau districts, while westward of 103° E. long. there stretches a forest region about which very little is known, but which is said by the natives to be inhabited only by savages and wild beasts.

Yadrintseff's *Siberia*.

Politically the country is divided into sixteen provinces, of which the following seven are in the delta mentioned: Bac-ninh, Sontay, Hanoi, Hai-Dzuong, Hung-yen, Nam-Dinh, and Ninh-Binh. Five provinces constitute the upland districts, viz., Cao-Banh, Lang-son, Thai-Nguyen, Tuyen-Kwan, and Kwang-yen; while the forests form the province of Hung-hoa. The main geographical feature in the country is the Song-koi, which, taking its rise near Tali Fu, in Yunnan, enters Tong-king at Lao-kai ("the Lao boundary"), and flows thence in a southeasterly direction to the Gulf of Tong-king. It was this river which mainly in the first instance attracted the French to Tong-king, as it was believed by the explorers that, forming the shortest route by water to the rich province of Yunnan, it would prove also to be the most convenient and expeditious means of transporting the tin, copper, silver, and gold which are known to abound there. This belief has, however, proved fallacious. The upper course of the stream is constantly impeded by rapids, the lowest being about 30 miles above Hung-hoa. Beyond this point navigation is impracticable during the dry season, and at all other times of the year goods have to be there transferred into flat-bottomed boats built for the purpose. Within the limits of Yun-nan the navigation is still more difficult. Near Sontay the Song-koi receives the waters of the Black river, the Clear river, and other streams, and from that point divides into a network of waterways which empty themselves by countless outlets into the sea.

Hanoi, the capital, is a fine city, and stands on the right bank of the Song-koi, at a distance of 80 miles from the sea. The commercial town extends along the water face for a distance of a mile and a half, while behind it stands the citadel, which encloses within its walls the palace, the treasury, the court of justice, the royal pagoda, the prison, the barracks, public offices, and official residences. Embroidery and mother-of-pearl work are the principal industries of Hanoi, which never has been and probably never will be a great commercial centre. But, notwithstanding this, the population is said formerly to have numbered 150,000, a number which has of late years probably been reduced by at least one-third.

Next in importance to Hanoi is Nam-Dinh, on one of the lower branches of the Song-koi. It is the centre of an extremely rich silk and rice district, and was before the war a great resort of Chinese merchants. But the chief place of trade is Hai-phong, on the Song-tam-bac Canal, 14 miles from the sea. This is the port of Tong-king, and its trade represents the foreign commerce of the country. In 1880, the last year of anything like normal trade, goods were imported to the value of 5,467,315 francs [$1,055,-191.80], and the exports amounted to 7,507,528 francs [$1,448,952.90]. Of the imports 34 per cent. consisted of English cotton goods and yarn, 21 per cent. of opium, 11 per cent. of Chinese medicines, 9 per cent. of Chinese water-pipe tobacco, 5 per cent. of tea, and 20 per cent. of miscellaneous goods. From 97 to 98 per cent. of these goods came from Hong-Kong. Saigon furnished about ½ per cent., and rather more than 2 per cent. represented the trade from Annam and elsewhere. The exports were in the following proportions: rice, 39 per cent.; raw silk and silk piece goods, 21; tin, 16; lacquer oil, 6; and miscellaneous goods, 18. Of these 79 per cent. were shipped to Hong-Kong, 16 per cent. went to Saigon, and the remaining 5 per cent. were distributed among the coast ports.

The mineral wealth of the country is doubtless considerable, though so little has been done in the direction of working it that it is impossible to form any idea of its richness. According to Major-General Mesny, there are flourishing gold-fields in seventeen districts, while silver and copper mining occupies a great deal of native and Chinese labor. Only very small quantities of these minerals, however, are produced in evidence.

The population of Tong-king is estimated at about 12,000,000, and consists of Tong-kingese, Chinese, and an admixture of Lao from beyond the western frontier. The Tong-kingese belong to the Indo-Chinese stock. They are taller and a finer people than the Annamese, and they are more frivolous and excitable than their northern neighbors, the Chinese. Their intelligence is, generally speaking, of a very low order; they are dirty in their habits; and their natural timidity serves to make them deceitful. As traders they show little enterprise, and are quite unable to compete with the Chinese, into whose hands the commerce had, before the arrival of the French, entirely fallen. Their spoken language is allied to the Cambodian, while Chinese forms the medium of literary communication.
